## A Parcels Post Tunnel Railway

### Transporting Mail Automatically by a New System

*[The advent of the Parcels Post will probably create a demand for means of transporting large numbers of parcels by some more expeditious and less costly interrupted method than the hoist, drum, vehicles or motor cars that must be relied upon for the present at least. The following article describes one system which has been constructed for demonstration purposes.—EDITOR.]*

Placing a parcel in the car. The space is sufficient to hold six ordinary mail sacks, or many Parcels Post articles.

IN five of our big cities, namely New York, Chicago, Philadelphia, Boston and St. Louis, a large part of the first-class mail is transported between the post office and branch stations and railway stations through underground pneumatic tubes. These tubes are 8 inches in diameter and the letters tied up in small bundles, are dispatched in steel carriers which fit like a piston in the tube, and follow one another in rapid succession. There are some routes—for example between railway stations, or between general post offices and railway stations—where it is desirable to transmit the mail in sacks or post boxes that are too large to be sent through the pneumatic tubes. A commission has recently been appointed by the Postmaster General to investigate the feasibility and practicability of an underground tube or tunnel between the new post office located at the Pennsylvania Railroad Station, and the Grand Central Depot, in New York city, which will be large enough to transmit the mail in sacks.

An automatic tunnel railway has been designed that can be laid either underground or on the surface, in which small cars are propelled by electric motors mounted on them, in much the same manner as ordinary trolley cars, but with this difference, that there is no attendant on the car to control it. A demonstration plant of this new system has recently been erected on a vacant lot in Cambridge, Mass., opposite the site of the new Technology buildings by the company that operates the pneumatic mail tubes.

It consists of a galvanized iron building 60 feet long, for a station, a tunnel and track nearly a third of a mile in length that begins and ends in the building, and a car to run on the track. Inside the station are located an electric generator, controlling switches, instruments used in making experiments, space for loading and unloading cars, and means of switching the cars from the main track

The tunnel railway car is cylindrical in form, about 25 inches in diameter and 7 feet 3 inches long, large enough to hold an adult. There is one supporting wheel and two guide wheels at each end.

A demonstration plant of the new automatic railway tunnel system. It comprises a tunnel and track nearly one third of a mile long and begins and ends in the station in the background. Car is position on the track.

An automatic tunnel railway that can be laid underground or on the surface, in which cars are propelled by electric motors, in much the same way as ordinary trolley cars, but with this difference, that there is no attendant on the car to control it.

As the car stops the shoes are unlocked, and the car may be moved out of the way of the following one.

to sidings. Leading out of the building is a tunnel made of 30-inch diameter cast iron pipe, similar to ordinary water pipe. Four rails are laid inside of the pipe, one on the bottom to support the car, one on each side to keep it in an upright position and an insulated conductor rail on the top. This pipe or tunnel is 234 feet in length and includes a bend of 90 degrees. The track extends beyond the pipe in a skeleton tunnel formed of cast iron hoops at intervals of three feet, to which the rails are attached. This skeleton construction is used for the rest of the distance around a rectangular space, terminating in the station. Part of the way it is supported on trestle work to make an ascending and descending grade of 5 per cent. The total length of the track is 1,534 feet and includes four curves of 50 feet radius. No shorter curves or steeper grades would be required in underground lines for regular service. At one point a short section of concrete tunnel has been constructed of elliptical cross-section 6 feet high and 7 feet wide to show how two tracks can be laid in a single tunnel. In some places a single concrete tunnel is preferable to two cast iron pipes, and it has the further advantage of giving freer access to the tracks.

The car which runs through the tunnel on the 1 rail track is shown in the accompanying photographs. It is cylindrical in form, about 25 inches in diameter and 7 feet 3 inches long. The space for mail and parcels inside the car is 24 inches in diameter and 4 feet long sufficient for six ordinary mail sacks, and if used for parcels post would be ample for a large number of miscellaneous parcels. The opening through which the car is loaded and unloaded is closed by a double-hinged cover that can be opened from either side. There are one supporting wheel and two guide wheels at each end of the car. The supporting wheels have double flanges, and one of them is connected through

(Continued on page 16.)

Four tracks are laid on the inside of the railway, one at bottom to support the car, one on each side to keep it upright, and a conductor rail on top.

# Scientific Management for Scientists

"The Bridge." The Trust Idea Applied to Intellectual Production

By Professor Wilhelm Ostwald

**WILHELM OSTWALD** must be reckoned among the founders of the modern science of physical chemistry. As the director of the Physico-chemical Institute at the University of Leipzig he not only himself contributed a lion share toward the upbuilding of this science, but by personal encouragement, teaching and writing, he has done more than is probably realized by all but a few to assist in the making of such men as Arrhenius, Brody and others. It will be remembered, too, that one of von Hoff's principal publications appeared in an early issue of the *Zeitschrift für physikalische Chemie*, then newly founded by Ostwald. Of late years, since laying aside his professional duties Ostwald has devoted his main efforts to philosophical work and to the support and propaganda of movements relating to various phases of scientific and public activities.—[Editor.]

Within the last century or so the world has awakened to a realization of the fact that, of all the social activities of humanity, science in its broadest sense, is the most important. It is true that as yet the appreciation of this state of affairs has failed to find adequate expression in a practical way, and the so-called civilized nations are to-day spending incomparably more for the maintenance of barbarous military organizations than for the scientific development of problems relating to the culture of mankind, although the former are specifically destructive of energy and persistence in their action, while only the latter work for energy concentration and upbuilding. The leading spirits of all nations, however, have long since come to a clear understanding of this situation, and accordingly we see numerous institutions, universities, academies, scientific societies, etc. engaged in energetic and efficient activity in the effort of extending the entire field of human knowledge to the utmost.

The phase of this field which has not as yet been satisfactorily organized is essentially that which relates to the character of the knowledge after which we are to strive. Through a perfectly natural process of his torical evolution many still regard a mere knowledge of the past, a mere accumulation of facts, as real science, and only slowly, under the pressure of the exigencies of our day, the fact is gaining recognition that all science has one and but one purpose, viz., that of predicting the future. Hence every branch of knowledge which claims the right of cultivation by humanity at large, or by an individual nation, must, first of all, justify its existence and prove its claims to social support by demonstrating its social value—which consists in nothing more nor less than its capacity of forecasting the future, and thus influencing it in a direction favorable for humanity at large.

Thus, for example, as has been clearly shown in the development of medicine in the last few decades, it is now merely a matter of time, and especially of money, whether and to what extent the diseases which are the scourge of the people, such as tuberculosis, can be exterminated, and humanity thus be freed from one of its direst plagues. The successful war waged against a number of febrile diseases by an investigation of their mode of propagation through the agency of mosquitoes has resulted in the opening up of great tracts of territory on our earth, which were hitherto uninhabitable owing to the prevalence of such diseases, and has thus greatly increased the total population which can find sustenance and be accommodated with some degree of comfort upon our globe. At an expenditure of a few millions of dollars it would be possible to relieve in exactly the same manner greater and more difficult problems, and, I repeat it, it depends merely on our ability to anticipate how soon and how successfully such work will be actually realized.

While the financial means for carrying out work

which obviously and directly serves for the welfare of the community are obtainable with comparative ease, more difficulty is experienced when the effort is made to engage assistance for some abstract scientific work, which can be applied only in the third or fourth instance to the direct amelioration of human conditions. But such science also deserves the most assiduous and careful attention. The question whether a given knowledge can or cannot serve for forecasting the future, need not be restricted to the inquiry whether such prophecy relates to possibilities of direct practical ap-

an undertaking, comprising the whole province of chemistry, is, at the present day quite unthinkable for a single individual. Even the subdivisions, as organic chemistry or physiological chemistry have grown so vast, that there is probably no man living at the present day who can command such a division in the same way as years ago Berzelius covered the entire field.

What has been said of chemistry is equally true of the numerous other branches of science. Everywhere complaints are made by workers and investigators that it is becoming more and more difficult to obtain a complete survey even in the current scientific production of the day.

The conclusion is brief in that at present the scientific production exceeds the human capacity for assimilating it. The ratio which the production of new knowledge bears to our means of disseminating and utilizing the same has become modified to the detriment of the latter task. This is a perfectly natural phenomenon for the production of knowledge is a matter of such primary importance, that it has received very predominant attention on the part of the most enlightened upholders of humanity. It is only in our own day that the second problem has become more and more pressing in view of the conditions depicted above. It is true that in certain of the smaller subdivisions of human knowledge, such as technical organization for the purpose of effecting the assimilation in question has taken place. In particular to chemistry the debt is due on the part of the state of the scientific work of the Division of the Annual Review by Berzelius, through which the total production of a year is brought together in orderly sequence and arranged in handy form for future reference. But this method of recapitulation is no longer sufficient with modern high speed of production and thus, for instance in the *Chemisches Zentralblatt* of the German Chemical Society we see an attempt to communicate to the world at large the current production with the minimum loss of time possible. Such abstracting is very widely developed in the field of chemistry and in other sciences also. The great chemical societies of all civilized nations have each organized a separate abstracting service, which seeks to cover comprehensively the total scientific production of the world in the form of short abstracts.

It will be only now that this method is attended with great waste of energy. Not only are there three hundred abstracting centers among English-speaking nations—one controlled by the American Chemical Society, another by the English Chemical Society and in a certain measure by the Society of Chemical Industry—but in addition to these there are at least five or six abstracting agencies in the German language devoted partly to the entire field of chemistry and partly to large subdivisions thereof, in addition to those there are similar publications of the same character in French, Italian, Russian, etc. Every paper published is therefore abstracted independently at least in three and in this way an unnecessary waste of energy is incurred which is in no way inherent in the matter at issue, but is purely the result of lack of organization.

What I have stated here from personal knowledge with regard to the lack of organization in chemical sciences, is in a sense in precisely the same way in the other sciences. A few domains in which co-operation is particularly important such as astronomy and meteorology are considerably better organized in proportion to their special needs. These organizations are international, but are restricted to certain narrow fields of pure and applied science. Other international organizations, which theoretically cover the whole field of science, such as the Association of Academies, have not

PROFESSOR WILHELM OSTWALD

plication. Every anticipation of the future may sooner or later become important. A very good example of this is the development of organic chemistry, which originated in Germany in the hands of Liebig, primarily as a matter of purely scientific research and which has since then made Germany the unquestioned peer in the world's chemical industry.

We can therefore say—speaking very generally—that at the present day a great deal is being done for science. Indeed, at times it almost appears as if too much were being done, for, if we imagine from any worker in one of the large divisions of science about the present state of our knowledge in such field, the answer is almost invariably a complaint that it has become practically impossible for the individual to follow the total production in his science, which has grown to gigantic proportions. While in the first half of the last century one head, such as Berzelius, was capable of completely commanding the entire field of chemistry, as that he was in a position for many years to write his famous "Annual Report" (*Jahresbericht*) on the advances of chemistry, and to give an authoritative statement of the value of the researches covered, such

yet acquired a form of activity which should insure for them co-operation with economy of energy in the entire field of science, so that here also the problem still remains to be solved.

Now it so happens that at the present time, in an entirely different field, namely, that of finance, a process is going on which may be regarded as a model for the organization of sciences and intellectual work. The recognition of the fact that competition alone is the most energy-consuming and impracticable of all methods by which opposing wills can be brought into equilibrium, is gaining a stronger and stronger foothold. In place of bitter competitive strife among related in Germany and commercial nations, all are going on everywhere the inverse process of the combination of analogous enterprises for joint collaboration and for the rational distribution of the several functions to such parts as are, through the general flow of circumstances, best adapted to perform the same, or in other words, as are in a condition to carry them out with the highest efficiency of energy consumption.

The process which we thus see going on in the world of economics must necessarily unfold itself also in that field in which the highest possessions of humanity are treated, namely, the field of intellectual labor. The need has become urgent that the total work of this activity of the human race be so organized and brought into harmonious union that no energy be wasted. Energy is wasted where one and the same piece of work is performed several times over, as we know is the case, for example, in the distracting current (chemical) literature, and energy is also wasted where essential individual pieces of work are not performed under the most favorable conditions with the best auxiliaries available at the present time. An organization of the world's intellectual work would therefore have to solve the problem of exerting a favorable influence in these two directions.

If, now we ask ourselves how such an organization could shape its activity, the answer is as follows. The highest creative productions in science will have to be left as before to individual high gifts and talents, and all that an organization can do here consists in placing the mechanical aids for such work at the disposal of those who are capable of carrying it out. In this direction a great deal has already been done, as was remarked above, both by private initiative and by the state. The work of this character, then, cannot very well be organized. At the other extreme, on the contrary, there is every possibility of organization. The possibility of organizing that is in a way, establishing some uniform and simple plan, is given in principle to all of those portions of intellectual work which are simplest and most widely distributed, for the simpler a matter is, the more easily can it be made independent of the individuality of the worker, and the more readily can it be replaced by, as it were, factory methods of production and a mechanical mode of procedure. With this point in view, then, an international institute was founded last year in Munich, under the name "Die Brücke" ("The Bridge"), which deliberately and positively follows the plan of undertaking the organization of scientific work, not from above downward, as hitherto, but from below upward, by first of all, introducing uniformity and effecting a saving of energy consumption in those things which can be thus rendered uniform without prejudice to the main task itself. Such are more particularly matters of detail relating to the technique of the production and use of publications and libraries. By far the greater part of science is, at the present day, recorded in the form of the printed word, whether in writing or print, and consequently a practical and thoroughly efficient "get up" of this fundamental tool of all intellectual work represents a problem of fundamental importance.

Thus, the establishment of a definite scientific scale of size for books and publications of every kind, has, for example, been one of the first tasks undertaken by "Die Brücke." If we reflect how very much waste all labor writing and printing would be if it were restricted to uniformly upon paper in a series of systematically well regulated sizes, how much less space would be taken up by books in our libraries if they all had the same height and breadth, how much easier the management and the use of all collections of printed documents would be, had we not continually to contend with the difference in the sizes of the volumes, it will be seen that this seemingly trivial matter, in point of fact, lies at the base of all rational organization of scientific work.

The work of "Die Brücke" is in a way restricted to this. Part and parcel of this purely technical organization, which comprises, in addition to the work mentioned, a number of similar tasks such as the preparation of copies, the cultivation of libraries, etc., etc., is also the organization of the intellectual work already accomplished and of that still in progress, as regards its arrangement according to subject, author and institution. "Die Brücke" is planned as a central station, where any question which may be raised with

respect to any field of intellectual work whatever finds either direct answer or else indirect, in the sense that the inquirer is advised as to the place where he can obtain exact information. Just like a telephone central, "Die Brücke" is intended to place every investigator in communication with every one of his fellow workers and to unite his field of work with every other field, and in this manner ultimately to establish a central for the entire unlimited field of intellectual work, by making use of which every person can automatically find his place in the great organism of the entire intellectual world, working with the minimum waste of energy.

Within the last few years successful efforts have been made in America to introduce the idea of scientific management in all sorts of fields, so that we may expect with confidence to find there a responsive audience when we speak of the organization and systematization of the world's intellectual work. "Die Brücke" has only recently come into existence and is therefore still engaged with preliminary work in Germany, the place of its origin, but we believe that we can confidently assert that our first brother institution, which will work together with "Die Brücke," according to the same principles and with the same aims, will be opened in the United States, the energetic and determined population of which seems best adapted, not only to the realization of this plan, but also to the organization, but also to secure for it a practical realization.

### The Military Supremacy of the Air—II

By Theodore M. R. von Kéler

(Concluded from the SCIENTIFIC AMERICAN, December 28th, 1917, page 1500)

WHILE France possesses a goodly number of airships of the Lebaudy and Clément Bayard type several years ago, the rapid development of the swift aeroplanes placed the large airship in the background, and it was not until the Zeppelins succeeded that France awoke to the fact that it had allowed Germany not only to catch up in this particular field, but to set the pace for other nations to follow. The need for large ships capable of staying in the air twelve hours or more, at an altitude of 500 feet and traveling up to 100 kilometers without landing, was felt, and the new law provides for several new ships of not less than 8,000 cubic meters (282,516 cubic feet) during the year 1918, more ships are to be constructed, until the next battle ship fleet is completed. In the first-class class of ships. Therefore the number of ships is always to be kept ready for service, old types are to be constantly improved or replaced by new ones, similar to the programme followed in naval aviation.

In the report of Clément to the French Senate on the subject of airship construction, special emphasis is laid on the excellence of the rigid type. The separate compartment idea is also advanced, as utilized in the Zeppelins. The arrangement of the hull in the form of the Zeppelin ships are recommended for use on the new French ships now building.

It is but natural that such extensive plans for increase in the size and number of the ships should demand similar plans for the housing, transportation and filling of these giant plants. The big fortresses, Verdun, Toul, Epinal and Belfort are fully equipped as aerial "incubators," while Maubeuge, Reims, Châlons-sur-Marne, Châlons-Meuse and La Motte-Breuil are being prepared for the reception of the ships.

The great movements of rail have shown that aeroplanes, in order to be of real value to an army, must be capable of rising from the ground anywhere without the necessity of depending on a permanent base. The aeroplanes are naturally a real means of taking the machine army for transportation, this was one of the tests of army aeroplanes last year, and has been made more rigid this year. It is now required that aeroplanes can be taken from the motor truck, put together and made ready for flight in a space of ten minutes. Specially designed motor cars accompany the aviation companies, carrying spare parts, supplies, wireless outfits and even complete machines for "dark-rooms" conditions.

In order to be absolutely independent of road conditions in a hostile country, some of the aviation companies will be attached to cavalry and artillery divisions, and the horses of the latter will be utilized in towing the aeroplanes across country, where it is desired to move fast and keep the presence of the machine hidden from the enemy.

What type of flying machine is most suited to military work, is still a much mooted question. The rapid development of the various types renders this question impossible at the present time, but two or three main types are preferred to single. The military, quite sensibly, contends that the handling of the aeroplane itself is at present such a difficult and comparatively complicated matter, that no opportunity is

left to the aviator to take proper heed of the ground below him, to make sketches or notes, or to transmit and send wireless messages. To take any of the most important duties of the military aviator, an observer should take a seat in the machine, whose sole occupation would be the reconnoitering of the enemy's position and an examination of the territory over which the machine flies. To take any of the other, more experienced officers of the general staff are to be used, leaving the youthful lieutenants in charge of the flying.

An aeronautic section of the French army consists of eight aeroplanes and fourteen motor cars, divided into four columns. The first column, of the most important, with single seats, for fast superficial observation and delivery of orders, the second has two biplanes with double seats, the third has aeroplanes with two and three seats, while the fourth, or reserve section has one single and one double-seated machine. Each section comprises seven pilots and fifty non-commissioned officers and men.

Besides these "regular" aeronautic sections there are a number of especially fast and powerful machines, capable of carrying two observers each in addition to the pilots, for emergency work. These machines are directly under the orders of the commanding general, are kept near his headquarters, and are able to cover a territory of not less than 100 miles radius.

The second column, of the French army, has twelve biplanes with single seats, for fast superficial observation, while before the end of this year no less than 334 machines (30 triplanes, 180 doubles and 144 singles), valued at \$1,000,000, operated by 286 military pilots and 210 observation officers, will be in service. The average life of an aeroplane is fixed at two years and no operating cost \$500 annually for each machine.

During the great artillery maneuvers in March of this year, aeroplanes were used in determining the firing efficiency of the guns. Six biplane single-seated monoplanes, four German double-seated biplanes, and three triple-seated biplanes were used in the tests with remarkable effect. While the officers are naturally reticent about the exact results obtained, it has been positively stated that any hostile battery could be destroyed in a few minutes by means of the aeroplane observations, provided it was located within shooting distance. Particularly the aeroplanes with two and three seats did good service, and monoplanes with single seats are not likely to be in this work.

France pays special attention at present to three things designed to throw or drop explosives from soaring aeroplanes on moving trains, on bridges, powder magazines, etc. It is, of course, self-evident that the first hostile action on the part of the enemy is to be followed by a descent of a flock of French aeroplanes upon frontier towns and fortresses. Bridges would be destroyed, railroad tracks demolished and magazines exploded, thereby greatly hampering the German advance after mobilization. Military aviators do not place much value on machine guns designed for shooting into the air, and less on rifles installed on the aeroplanes for horizontal attack. It appears to be the general opinion among those that the mastery of the air must be fought in the air, and that aerial battles will be won by skill in operating the machine and high speed. According to their idea, an aeroplane would have to soar over or above its enemy and then drop an explosive on it. To do this, the machine must be high-powered, and must be able to rise and descend rapidly. And that these considerations have passed the romance stage, and are hard facts of the present day—the next big continental war will show Germany is watching the activity of the French with eagle eyes, and the soldiers of the German army are determined to permit themselves to be left in the rear in the fight for control of the air.

## High Speed on No. 20 Crowsnest

To the Editor of the SCIENTIFIC AMERICAN

After following very closely the controversy in your columns precipitated by the *Springfield Republican* and the complete knocking out by you of every leg which he attempted to stand on in his argument, my attention is drawn to the enclosed half-page advertisement in the *Springfield Republican* to-day, which I presume is being published extensively in the prominent papers through the eastern part of the country, as a large amount of the stockholders' money is being squandered at the present time in this manner.

The point to which I wish to call your attention and ask for technical information on is the first paragraph, which has been marked, as in your argument the statement was made that the No. 20 Crowsnest over the New York and Philadelphia daily crossed for the trains at full speed. As this advertisement is published at the same time that the "truth has been told," it would appear as though a misstatement was made, as, without further knowledge, I should much prefer to tie to statements which you made regarding the daily operations on the Pennsylvania.

H. F. SCHAEFER

Springfield, Mass.

[The overturning tendencie of a No. 10 crossover are nearly four times as great as those of a No. 20. The Pennsylvania expresses daily run through No. 20 crossover at far higher speeds than the slow order speed of 45 miles an hour, and they do so without risk.—EDITOR.]

## The Reindeer in Alaska

To the Editor of the SCIENTIFIC AMERICAN

The note about the Alaskan reindeer herds in the issue of August 10th, 1912, calls for some statement of facts as commonly but accurately known throughout interior Alaska. Any success resulting from the introduction of the reindeer into Alaska has been confined entirely to narrow strips of land bordering the oceans, and capable of supporting but a small population. A few, a very few, people have been able to make a living with them. These cases have been quoted repeatedly by other hand, continued attempts to introduce reindeer throughout the interior have been expensive failures, because of the scarcity of the variety of moss which the reindeer requires. More moss can be found almost anywhere, but the only kind upon which reindeer can live is found only occasionally. Consequently, the reindeer animal, it is impracticable for the greater part of the country, since long detours must be made in search of food. Such detours are expensive and often unsuccessful. I recall one instance, happening at Anvik, in the winter of 1908 to 1909. The superintendent of schools for the Government came in one day with several reindeer, drivers, etc. They had hunted for suitable moss in vain, and now had to hire native guides to lead the way to the nearest patch, some twelve miles away. Arrived there, they had to shovel snow several hours in order to make it possible for the reindeer to reach their food. The superintendent was at the time on his way to remove the small herd at Holy Cross, which had been a great success to the Government, and he was now attempting the continual service of between thirty and forty men, whose main duty was to shovel snow off the moss for the herd.

Your article states that "it is expected that the exportation of reindeer meat will soon become an important industry." This is absurd, and can plainly be seen from the fact that thousands of moose, as well as sheep and poultry, are annually imported to supply the meat needed. There is a continuous but unfilled demand for mutton and reindeer meat. The price of meat here is far higher than in the States, so that a surplus of reindeer meat from the coast herds could move more profitably be shipped here than elsewhere. As it is, the Government itself buys hundreds of moose to supply meat for the army posts and for the Signal Corps mess stationed along the telegraph line.

So it is that, both as a draft animal and as a meat producer, the reindeer has proven a failure in Alaska except in the localities. Furthermore, the trails, the Alaskan dig (Hauls or Walenets) is the present staple. On the main trails, hard packed and constantly used, stage coaches and horse-drawn "double-enders" slide prevail. At each station of the Signal Corps there is found a horse or dog, according to the nature of the surrounding place. Meat is shipped in hundred-ton lots or driven in from Cordova or Valdez in loads of hundreds. Practically all reindeer herds have been withdrawn from the interior, since careful attempts have shown that their maintenance for the purpose of a meat industry is not feasible, considering the limited success in a few places,

it is little more than a quibble to make such ambitious claims for the Alaskan reindeer herds.

Chena, Alaska.

A. W. WILLIAMS.

## Artificial Respiration With a "Lemon Squeezer"

To the Editor of the SCIENTIFIC AMERICAN

Lately a great deal of interest has been shown in resuscitation from electric shock. We live in an age of electricity, and electric accidents are getting to be of every-day occurrence in most places, and, what counts more with the electric companies, we have now a national employers' liability law as well as similar laws in some of the States. There have been their pet defenses away from the companies and lay them open for damage.

Everybody seems to agree that in artificial respiration must be placed our greatest hope in such cases, but how this is to be done there is a difference of opinion. The thorax or chest resembles a rubber bulb like those we use on steamers. Now, we all agree that such a bulb can be emptied of air by compression, provided there is a way for the air to get out. After the compression the rubber bulb regains its former size and shape through its inherent elasticity and in doing so it must suck in air. The chest in its method of artificial respiration is worked just like a rubber bulb. First a way for the air must be provided. If we put an unconscious man on his back which is the natural and handsomest way to work him, his tongue will fall back, close his larynx, and so render his upper air passages, mouth and nose useless. To prevent this, an assistant has to grasp the tongue with a cloth and pull it out to the limit. The neck should at the same time be stretched. If there is no bystander to do this, I put a rolled coat or some other soft neck and I have stretched over his pulled-out tongue and lower jaw, knitting it in the back of the neck. Then the common procedure is to compress the lower part of the chest with my hands. In adults I used to straddle the man and throw my full weight

Method of using the "lemon squeezer" I, active inspiration, II, deepest unassisted expiration, III, deepest expiration assisted by levers.

on them—175 pounds. There is no doubt in my mind that this is the most efficient method of artificial respiration, but it is so tiring for the operator that it becomes necessary to take turns at compressing, especially since artificial respiration must be kept up for a long time in all such cases.

Of all the mechanical appliances the lever is the simplest and most efficient, and it occurred to me that a modified lemon squeezer would work well on the chest. So I took two boards for levers, and I kept the hole in the board with a cord for a fulcrum. Two boards, one about 10 by 3 by 1/4 inches, will do. I shape them with my pocket knife into flat Indian clubs, drill a hole through one end of each, run a string through the hole in one lever, loop the string from pulling through by a knot, and am ready for business.

When anybody is shocked around electric work, he should be put flat on his back, his neck stretched, his tongue pulled out to the limit, and his chest compressed with the levers or "long clothes" as I call them. They are simply attached as handles to the chest, and the chest worked like bellows. The operator (in electric works the foreman should be so trained) slips the cord fulcrum under the man's chest, runs it along the hole in the other lever, adjusts it with a slip knot to the arm of the patient so that the cord is taut between the back and the handles not quite parallel but a little divergent in front. Then he compresses the chest slowly and easily, keeping time with his own breathing. This he keeps up till a physician arrives and takes charge.

Such artificial respiration is, as far as the change of air into and out of the lungs is concerned, similar to natural respiration, but it is not equal to it. Anyhow, it is the best we can do till a physician arrives and tries to restore the natural heart by other measures.

Cambridge, Cal.

## Risks in Straightening Rails

To the Editor of the SCIENTIFIC AMERICAN

Some few years ago I visited a large mill where rail-road rails were being made. The person acting as guide showed me all of the various manipulations, and in the end I saw them being made straight by a couple of workmen. The process consisted of sagging along the rail, which was shifted back and forth until a press, which was thrown in and out of action as the various kinks and bends were subjected to the pressure to straighten them.

I stood there interested in the work. I saw two rail men under the pressure exerted. Having noted a number of articles in the SCIENTIFIC AMERICAN on rail failures it occurred to me that possibly not a few of these failures might be traced to a small incomplete fracture caused at the time of straightening, developing into a complete one. I would not attempt to offer any suggestion as to a better way to straighten a rail, but surely any act which would break a rail could develop a crack which might develop into a complete fracture with disastrous results.

Do you not believe that a careful examination along these lines would result in an explanation of why an apparently sound rail suddenly goes to pieces?

Opoli, Utah.

[Our correspondent draws attention to a possibility which has been criticized as liable to be permanent injury to a rail (old straightening is undesirable, to say the least, the rails should never be straightened when they are below a certain fixed temperature.—EDITOR.)

## The Transmutation of the Elements

To the Editor of the SCIENTIFIC AMERICAN

The interesting article which appeared in the August 24th issue of your valuable paper, on the *Base Metals Changed to Gold?* attracted especially my attention because closely following an article wherein the same argument is masterly treated by Prof. J. Soddy of Glasgow University.

Let me consider two possible sides of the transmutation problem, viz., transmutation from light to heavier atoms, weight for weight, and transmutation from heavy to lighter atoms a weight elements.

The first side of the problem offers enormous difficulties and is obviously unworkable.

The latter from your writer's point of view, seems to be solved by Sir W. Ramsay's and Cameron's experiments.

Mr. Rutherford's criticism is reported and I will add that of Mr. Soddy, who clearly states in the article referred to that "The energy of disintegration changes is thus of the order of a million times greater than the energy of ordinary chemical or molecular changes. The energy evolved from the disintegration of a single atom is detectable by radioactive methods, whereas a million million atoms of any non-radioactive element at a quite undetectable quantity even with the spectroscopic. For this reason the identity of the final non-radioactive product of the whole sequence of changes still remains uncertain."

As a matter of fact, Mr. Soddy is referring here to radioactive series disintegrations, not to artificially produced transmutation, but he next points out that "The fact that it has been found quite impossible even by the most powerful agents now known, to alter artificially the ratio at which a radioactive element is changing either to retard or to accelerate it, is obviously the corollary to the well-known impossibility of artificially transmuting one element into another."

It seemed to me necessary to note this discrepancy in judgments for the present, because of the importance of transmutation that is going to take the preponderant place among the big problems of modern science, both chemical and physical.

## Preserve Your Papers; They Are of Permanent Value

By taking a little trouble when a paper first comes to hand it may be preserved to form a permanent and valuable addition to the reader's store with which everyone should be provided. We furnish a neat and attractive cloth-bound binder which will be sent by mail, prepaid for \$1.50. It has good strong covers on which the name SCIENTIFIC AMERICAN or SCIENTIFIC AMERICAN MILLBROOK is stamped in gold and worn by which the number and year of issue of a bound volume is clearly marked. It is a most valuable addition to any library embracing a wide variety of scientific and general information, and timely and original illustrations. Save your papers.

Transmutation: The Initial Problem of the Future. SCIENTIFIC AMERICAN, 2 pp. 190-202.

# The Modern Automobile Torpedo

## The Story of a Great Invention

By Robert G. Skerrett

THE modern automobile torpedo so far as its inception is concerned is forty-seven years old. In 1861 Capt. Lupus of the Austrian Navy, realizing the potential destructive powers of a torpedo capable of self-propulsion, conceived a type of miniature fire-ship or boat, torpedo, which could be directed from a fixed base by guiding lines. Capt. Lupus proposed to propel his torpedo by means of clockwork or steam, but he had not personally the mechanical knowledge needed for the proper development of his weapon. At that time Mr. Whitehead, an Englishman and a man of exceptional mechanical skill, was in charge of an engineering plant at Plume, and to him Capt. Lupus turned for assistance. The net result of the association was the awakening of Mr. Whitehead to the field thus offered to engineering cunning. Abandoning Capt. Lupus' scheme entirely, Mr. Whitehead set about devising a torpedo capable of self-propulsion and self-direction—after once being started on its way—which, unlike the crude surface affair of Capt. Lupus, should be able to run under water and safe from gun fire.

financial position to obtain exclusive rights to the invention.

From the modest 14-inch torpedo of 1864, with its limited range and speed, we have reached to-day a weapon weighing more than 1,000 pounds and capable of covering ranges up to 7,000 yards—traversing this distance in the remarkably short period of less than seven minutes. This particular torpedo is the invention of Jent. Harcourt of the British Navy. In our own service we do not claim the same long range—4,000 yards being the maximum upon which we now place a military value, and the remaining speed at the end of this run is in the neighborhood of 28 knots. The explosive charge of the present-day automobile torpedo varies from 140 to 250 pounds of gun-cotton. The destructive force of a blow of this sort has been amply demonstrated recently by practical tests against the under-water bodies of fighting ships. To-day, the builder of battlehips can hope only to restrict the area of under-water damage by subdividing his ship below the waterline into numerous watertight compartments. The torpedo will probably not be able to sink a dread-

the value of the gyroscope, however, other minds promptly set about improving this instrument of lateral guidance. To begin with, the adoption of ball-bearings, finer balancing, and the refining of various moving parts made it possible to lengthen the directive period of the gyroscopes as well as to increase its sensitiveness—thus insuring a more reliable run and a speedier one by flattening the sinuous course. The next developments introduced an air-impulse, turbine-driven gyroscope, and then an electrically-driven Ory gear followed. These have done away with the shock of the original spring impulse and have naturally greatly increased the directive value of the gear, besides making it possible to fire the torpedo from a broadside and cause it to swing automatically through an angle of 90 degrees toward a target dead ahead. From a weapon that was a menace to friend and foe alike, the installing of the gyroscope has revolutionized the automobile torpedo, making it under some conditions even more certain of hitting its mark than that possible with the biggest of our modern guns.

For years the wonderfully compact and efficient

Sweating in the ends of the air flask or "middle body" of a torpedo.

No. 1 is the fore or head of the torpedo. 2 is the "middle body" or air flask. 3 is the after body of the torpedo.

### THE MODERN AUTOMOBILE TORPEDO

Some time in 1864 Mr. Whitehead built in secret his first torpedo. This weapon was a relatively modest effort, having a diameter of 14 inches, weighing but 200 pounds, and carrying a charge of but 18 pounds of dynamite. The motive power was compressed air stored at a maximum pressure of 700 pounds per square inch, and the torpedo was capable of making about 6 knots an hour for a short distance. As soon as this torpedo was subjected to test in the water, Mr. Whitehead was brought face to face with some of the harder problems of his undertaking. One of these was the task of properly controlling the submerged run. Instead of keeping at a uniform depth the torpedo divided its time uncertainly between the surface and the waterbed, and it was seemingly impossible to keep it within the desired bounds. After four years of patient experimenting Mr. Whitehead evolved his "balance-chamber"—for years guarded by every effort to keep it secret—by means of which the submergence of the torpedo became automatic, the movement of a pendulum combined with hydrostatic pressure serving to actuate certain controlling mechanisms which, in their turn operated the diving rudders. The Austrian government was the first to give official recognition to Mr. Whitehead's work but was not in a

position but it will be likely to so impair her military efficiency as to make her an easy mark for deliberate annihilation either by gun-fire or further torpedo attack.

Only a few years ago, comparatively speaking, the lateral course of the torpedo was decidedly uncertain, to put it mildly. The range and speed had been greatly improved, but the torpedo still had a way of departing suddenly and mysteriously from its intended course—sometimes coming back at the vessel from which it was sent to the no small dismay of all hands. This was not a pleasant thing to contemplate in time of war when the head of the weapon would be loaded with its violently destructive charge. At this critical stage in the history of the torpedo, the Ory gear was invented. Briefly, the Ory gear consisted of a gyroscope placed within the torpedo and so connected by intermediate power mechanisms with the directive rudders that the weapon could be held to a fairly straight course or, more properly, to a sinuous one consisting of a series of flattened curves alternating from right to left. The original Ory gear had a spring impulse, its directive force rapidly diminishing from the instant of starting, and it became quite useless after the torpedo had run something over a thousand yards. Realizing

three-cylinder Brotherhood engine was the best available motor for the automobile torpedo, but even with its progressive developments it had the inherent limitations or drawbacks of the reciprocating engine, and it was only logical that the torpedo builder should cast about him for a motor capable of utilizing still better the power stored in the air flask. The turbine was the natural solution of the difficulty.

All the while that the torpedo was improving in military value, the range of modern guns on shipboard was likewise undergoing substantial increases—making it possible for ships to fight at greater distances, and the torpedo expert realized, despite all that had been done to make his weapon more effective, that both the range and speed of the torpedo must be further increased if it were to meet properly the changed conditions. This was a staggering realization, because there were difficulties in the way of making a larger torpedo susceptible of easy handling, and it was not practicable to add much either to the capacity of the air flask or to the pressure of the energy stored therein. At this critical stage, American inventive skill found a way to surmount the obstacle. Mr. Frank M. Lewis, of the E. W. Bliss Company, made the startling proposal to heat the air stored in the flask, and thus to

came its expansion and multiply its propulsive capacity. The first American development of the super heater for this purpose consisted of means by which alcohol could be burned within the air flask—the heated air passing thence through the valve system to the engine or turbine and, while still relatively warm passing onward through the exhaust. Apart from propulsive advantages, superheating obliterated another objectionable feature of the older system in which the changes of temperature were so great—due to the rapid expansion of the compressed air—that the exhaust was frequently far below the freezing point. This caused the lubricants to congeal and, in turn impaired the action of moving parts. The British development of the superheater omitted the alcohol flame from within the air flask and put it between the reducing valve and the motor. This was an advantage in some ways. It did not require the heated air to pass through the delicate valve system, it fed into the engine the air at its most efficient temperature, and it made possible a nicer control of the pressure at the

during the entire run of the torpedo as he first did, he, too, heats the impulse supply outside and between the reducing valve and the turbine, but, in order to make use of more of the stored air than possible heretofore he causes the ignition of an alcohol flame inside of the flask toward the latter part of the run. By this means he is able to use to good effect 174 pounds of the original 101 pounds of the compressed air—thus increasing the range and the maintenance of higher speeds throughout the longer run.

Without giving away state secrets, the following table will show what the superheater has made possible in the case of an 18-inch torpedo. These figures are very instructive:

Speed in Knots.	Air Unheated	Air Heated
At 1,000 yards	15	11
At 1,500 yards	10	8
At 2,000 yards	24.25	38
At 2,500 yards	23.24	52
At 3,000 yards	15.20	28

called Calamine (i. e., "made of reeds"), in Lydia, which were not only driven by the wind but could be pushed about from place to place with poles.

Floating gardens—some natural and some artificial—have flourished in many parts of the world from early times. They are particularly advantageous in regions exposed to floods where a garden planted on terra firma would be ruined by these occurrences, while the floating garden is undisturbed by the rise of the waters. The famous floating gardens of Kashmir are a case in point.

The lake of Xochimilco, near the city of Mexico, is nearly covered with floating gardens called chinampas on which are raised vegetables and flowers for the city markets. They are formed of floating masses of water plants covered with soil and secured by poplar stakes. The latter take root and surround the islands with living hedges.

Among the largest of natural floating islands are those formed by tangled masses of trees and brush wood carried down by great rivers. On the Mississippi

Erickson's automobile torpedo of the TWA, built in this country, and tested at the United States Naval Torpedo Station at Newport.

This dirigible torpedo was designed to rival the Whitehead and the Lay torpedoes. It never survived the experimental stage. It was driven by compressed air.

One of the latest types of the Bliss-Leavitt torpedoes, showing the three separate sections of the torpedo in their assembled condition ready for service.

#### THE MODERN AUTOMOBILE TORPEDO

engine or turbine. However, like all good things, it had a drawback from a military point of view. When the air flask of one of our torpedoes is fully charged, the actual weight of that compressed air amounts to something like 101 pounds. The reducing valve, which regulates the pressure and supply of air to the motor—standing sentinel between the air flask and the propulsive mechanism—is designed to maintain a feed pressure of 300 pounds for the turbine impulse. When the pressure in the air flask approaches 300 pounds, the run of the torpedo is substantially at an end so far as its useful military speed is concerned. As the air in the air flask expands due to its gradual escape to feed the motor, the temperature is lowered sometimes even to below zero, and this remaining air is incapable of expelling itself from the flask for the purpose of effecting the propulsion of the torpedo. It has been found that when the superheater is outside of the air flask, of the total weight of 101 pounds of stored energy, not more than about 148 pounds are utilized. Again Mr. Leavitt's ingenuity has supplied a remedy. Instead of heating the air within the flask

This article has reviewed only the more startling features of development in the so-called Whitehead automobile torpedo, but it must not be imagined that there have not been numerous other directions in which the weapon has been modified and bettered to overcome the curbing of the defense. These, however, contriving as they do to improve effectiveness and precision of action in one direction or another, are matters of detail which cannot be touched upon within the space of this contribution—interesting as they undoubtedly are.

#### Floating Islands

THE imagination of man has always been impressed by floating islands. In ancient times such islands were regarded with superstitious reverence, and the romantic story of Delos—the natal Isle of Apollo and Artemis—is but one of many cases recorded in classical literature of vagrant islands in the sea. Pliny says that in the lake of Vadimonis there is a dark wood which is never seen in the same place for a day and a night together, and he describes the islands

and its tributaries these islands are known as "rafts." One of the most remarkable of these rafts began forming in the Atchafalaya, one of the lower arms of the Mississippi in 1778, and gradually increased until by 1816 it had extended to 10 miles in length, over 400 feet in width, and 8 feet in depth. Although it rose and fell with the water it was solid enough to support the growth of trees, some of which were 60 feet in height. This vast obstruction was finally removed by the State of Louisiana at great expense. The work began in 1848 and lasted four years. In 1850, even times a great raft in the Red River completely blocked the channel for 45 miles, until it was removed by the National Government.

Where a vast of vegetation borders the seashore the action of waves sometimes breaks off large islands. This was probably the origin of a remarkable floating island which was first seen in the Atlantic Ocean about 400 miles east of the New Jersey coast in July, 1882. Its area was about 9,000 square feet and it bore trees 30 feet in height. When again seen in the following September it had traveled over 1,000 miles.

## Turntable for Cars

IN the majority of garages there is very little room for the easy maneuvering of automobiles and a great deal of time is wasted in trying to turn a car about, particularly if it has to make a right angle turn to reach the elevator which will carry it to the shop. The accompanying picture shows a special form of turntable adapted to overcome the necessity of tedious maneuvering. The turntable is similar to that used for locomotives. It may be rotated by a single man by using a bar to engage any one of the several small levers in the outer edge of the table. The table itself is built of reinforced concrete and hence is proof against water and fire. The diameter of the table here shown is fourteen feet, so that it will take the largest touring car. It has been found of great convenience when adjustments or repairs must be made for the car can be swung around without any trouble to the best position to obtain all the available light.

Readers are invited to contribute photographs of novel and curious objects, unique occurrences and dangerous contrivances. Such as are found available will be paid for promptly.

An automobile turn-table for garages.

## New York's Cave of Stalactites

ONE of the most noteworthy forthcoming exhibits in the Mineral Hall, at the Museum of Natural History, New York will be the representation of a beautiful cave of stalactites and stalagmites. This will be a reproduction of almost an entire cavern recently discovered in the Copper Queen Mine, at Bisbee, Arizona. Here, a quarter of a mile below the surface during the mining operations of blasting for copper, a spacious chamber was uncovered containing a series of terraced like grottoes adorned with a wealth of magnificent and many-colored stalactites and stalagmites. Dr. Douglas and the mining company placed the find at the disposal of the museum. Dr. Edmund T. Cresson, Curator of Geology and in vertebrate Paleontology, with three assistants visited Bisbee to collect and bring back the original material so as to form an exact reproduction of the Arizona cave. A half a hundred boxes, containing the clusters of formations from the walls, floors, ceilings etc. were brought back. They weighed from one pound to nine hundred. The delicate task of setting up the pieces in the cave at the museum is being executed by Mr. William Peters, artist of the museum staff who accompanied the expedition to Arizona.

A steel frame 12 feet high by 8 feet wide forms the outside of the cave, which will be covered with limestone blocks, taken from the mountain under which the cave was found. These wonderful formations of stalactites and stalagmites are made through the evaporation of percolating waters. The most striking feature of the reconstructed cave will be a stalagmite 1 foot in diameter and  $\frac{3}{4}$  foot high, of a beautiful green color, and weighing about 300 pounds. This stalagmite is remarkable on account of the radiating clusters of pointed calcite crystals thick all over it but diminishing in size from the bottom of the column upward.

## Electricity and Diet

SCIENTISTS have been looking for some method of repairing the multiple ailments which are needed to keep up the human body by food in a concentrated state, so that it could be absorbed with less fatigue. On the other hand a French scientist, Prof. Bergonié claims that electric shocks will solve the problem. We have already mentioned some results which he obtained in this direction, according to the account presented by him to the Science Administration Congress. Since then he has continued his researches and arrived at results which have almost a sensational character. Before this he simply proposed the idea that electricity could be made to replace food that is by adding to the least energy absorbed by the body, so that less food need be taken into the system. At present he is making actual experiments which appear to prove this conclusively according to his communications

made to the Academy of Sciences. The experiments were made during the last few months at his laboratory at the Bordeaux University and fully confirmed his theories on the subject. His method, known as "diathermy," or application of low tension and high frequency currents to the human body, is able to make up for a part of the alimentation of the system by furnishing a large amount of heat to the body, instead of producing the heat from food materials which need to be consumed or indeed burned in the system. This giving rise to overwork of the physiological organs of the body. Such electric currents, as Prof. Bergonié says, will pass through the body without causing the least feeling, and with a current of 2 to 3 amperes strength and a voltage of 1,000 to 2,500 volts per hour about 1,000 calories of heat can be furnished per hour, this being over one third of the daily food ration. The following test will bring out the remarkable results which can be obtained by this method. He applied the electric treatment to a man 5 feet 10 inches high, whose weight before the treatment was only 110 pounds. The patient ate a great deal of animal food, but was in very bad condition, as he could not walk over 300 feet without needing aid. He was unable to work and was very sensitive to cold. After a series of treatments of 40-minute duration by the electric method, this corresponding to an absorption of heat equal to about 1,700 calories each time, the patient began to improve rapidly, and at the end of the treatment he gained considerably in weight. In fact, he then weighed as much as 140 pounds, which makes a gain of about 30 pounds. Dr. Bergonié states that the patient can now walk for hours without fatigue, and his physical vigor is restored to the normal. He is able to stand all degrees of heat, and his general appearance is very good. The author considers that the time is not far distant when all troubles due to insufficient nutrition will disappear under a series of electrical treatments by high frequency currents according to the general method of M. d'Arsenauval.

## A Frozen Whirlpool

WE have received from a reader in Schenectady, New York, the accompanying photograph of a most unusual ice phenomenon. As the result of rotary currents in a mill pond, a large circular piece of ice nearly six feet in diameter was formed and kept separate from the main body of ice, owing to its continuous motion. The disk was almost a perfect circle, and moved slowly from left to right. This phenomenon occurred last winter. The unusual condition continued for several days until the ice had obtained a thickness of nearly two inches.

The original cave in Arizona.

Reconstructing the cave in New York.

A rotating ice disk, naturally formed.

## Marcus Aurelius Unhoused

THE noble statue of Marcus Aurelius in the Capitol Square of Rome has suffered severely from the ravages of time. Recently it was found that the pediment bronze was urgently in need of repairs. The only thing to do was to remove the Emperor from his horse, and take him to the museum of the Capitol, where the repairs in his garments and the work on his limbs could receive proper scientific treatment. A scaffold was built over the statue and the Emperor was firmly bound by the legs and chest and then lifted from his horse by means of suitable tackle. Our illustration pictures him as he is being lifted and shows that even in this trying position he was not lacking in stolid gravity. While the Emperor was undergoing repairs at the museum his horse was completely holed in by a temporary wooden shack. When the figure was removed from the horse there was considerable agitation on the part of a faction of young Italians who were anxious to have him replaced by a statue of Omar. Fortunately for the memory of the great Marcus Aurelius, this agitation was unheeded by the authorities.

Statue of Marcus Aurelius removed from his horse for repairs.

## Power of a Microscope

By C. W. H. Macpherson

**A**MATEUR who has a microscope aims a great deal of the pleasure and interest to be derived from its use unless they are able to find the magnifying power of their instrument and to measure objects with which they are working. It is surprising how much more intimate an acquaintance with an animalcule or portion of an insect is obtained if we are able to say that it is  $2/10,000$  inch in diameter, or whatever else its dimensions may be.

In order to measure objects under the microscope it is first necessary to find its magnifying power, or, in case the instrument has several objectives and eyepieces and the tube can be changed in length, to find the magnifying power under the various conditions in which it is used. All the methods the writer has seen involve the use of an object of known length which can be observed under the microscope. This usually consists of a pair of lines ruled on a glass plate at known distance apart, and can be bought for a couple of dollars. This outline, however, is unnecessary if the following method is employed.

Take a good watch and measure the exact radius of the hour hand, that is, from the tip to the center of the pivot. Suppose this is found to be 0.57 inch. Then the path of the point in 12 hours will be  $2\pi \times 0.57 = 3.58$  inches. Therefore, it will move  $1/100$  inch every 2 minutes and 1 second. If the crystal is opened and the microscope focused on the tip of the hour hand, in 2 minutes and 1 second it will have moved  $1/100$  inch, and will fill the same purpose as the lines ruled on the glass. To the side of the barrel of the microscope fasten a piece of sheet metal with a small hole in one end and bent as shown. The distance between the hole and center of the eyepiece must be the same as the distance between the experimenter's eyes. On the table below the hole fasten a ruler running across the table 1 ft., forward and back from the operator and exactly 10 inches from the hole. This 10 inches is the arbitrary distance selected in this country for such measurements. The watch must be so placed that the hour hand is moving directly toward or directly away from the operator. Now, upon looking in the microscope with one eye and through the hole with the other, the watch hand and the ruler will appear to be one on top of the other. Note the exact point on the ruler where the hand is at any instant. Then let 2 minutes and 1 second pass and again note the position. If the distance moved is  $1/100$  inch it will mean a magnification of

$25 \text{ inches} = 250 \text{ diameters}$ . A little practice will enable a person to hit the time very closely. This can be repeated for various conditions, for power lenses a greater distance than 0.01 inch being taken for higher powers perhaps a shorter one.

The next thing is to construct a scale for the measurement of microscopic objects. The scale reads thousandths of an inch, but each thousandth inch is magnified according to the power of the microscope. Thus, where the magnification is 250 diameters the "thousandths" will be  $1/4$  inch apart. The proper length and division of the scale (or scales in the case of several objectives) can be figured and can then be drawn on a strip of cardboard. To measure an object it is only necessary to put the scale in the same position as the ruler in the first experiment. The object will then appear right on top of the scale and can be measured as easily as a carpenter measures a board. *Cautions.* Always hold the scale at right angles to the nearest edge of the table. If it is laid parallel to a line connecting the hole and the eyepiece it will be nearly impossible to read. The glass should be cleaned is easily proved by trial. Also remember that the scale must be 10 inches from the hole. If this is an inaccu-

Device for measuring the power of a microscope.

venient distance owing to the shortness of the microscope any other distance can be adopted, as 8 inches, but in this case each division must be  $8/10$  as long as for the regulation distance.

## How to Remove Black Paper Strips from a Film Pack

By Stanley P. Mellins

**I**n removing the black paper strips from a film pack such as commonly is used by countless numbers of

amateur photographers, trouble not infrequently is experienced by reason of the paper tearing off before it has been completely withdrawn. Under ordinary circumstances, in order to nullify the effect of the remaining piece of black paper, it is necessary to pull out the rest of the strip, thereby sacrificing one exposure. It is quite possible, however, to remove the section of black paper without destroying the exposure or disturbing the film remaining in the pack, with the aid of the summed portion from an envelope. The envelope flap first should be trimmed to the width of the film pack, an envelope made of fairly heavy paper would be better used, though almost any thickness will serve the purpose. Then if the gum is loosened, which by reason of the slippery nature of the envelope will operate to inhibit it, little difficulty will be experienced in slipping the improvised "flap" down between the torn-off paper and the next black strip in the pack. Care should be taken, of course, to ascertain that the summed portion of the envelope comes in contact with the torn paper and not with the next black strip. The envelope should be permitted to remain in position for about 10 minutes, or until the gum has had time to harden thoroughly, when it will be a simple matter to draw out the torn strip by grasping the free end of the envelope.

## An Interesting Static Electric Motor

By H. B. Dalley

**F**OR exhibiting in an entertaining way the effects of static electric attraction and repulsion, and for stimulating an interest in the observation and study of these phenomena, there is perhaps no form of demon-

The "tumbler" static electric motor.

stration appears more effective than a static electric motor. While examples of static motors have occasionally appeared, the degree of mechanical skill involved in their making has usually been such as to discourage attempts at amateur construction. The first and most extensively known of these is the "tumbler" motor here described should therefore commend it to the home experimenter.

The apparatus employs three large equal sized tumblers of this blown glass. The central tumbler, in vertical position, has a pivot pointed stem of  $3/16$  inch steel wire whose upper end enters a small indentation drilled in the exact center of the tumbler's bottom. A lower bearing is provided by fitting into the mouth of the tumbler a centrally apertured disk of stiff mica through which the supporting rod passes, the disk being secured in place with a little shellac applied to its edges. To keep the pivot stem from wearing the mica, a copper cone drilled to an easy running fit for the rod is attached to the mica disk with sealing wax. The tumbler, which is raised about an inch above the base, has cemented with shellac upon its outer surface eight equally spaced vertical strips of tinfoil  $5/16$  of an inch wide, with rounded ends, and of a length about  $3/4$  of an inch shorter than the length of the tumbler.

Then opposite sides of the inverted tumbler and quite close to it are placed two similar tumblers, right side up, their bottoms fixed with shellac into snugly fitting recesses bored in the wooden base of the instrument. Each of the first tumblers has cemented upon its inside surface exactly facing the central tumbler a vertical strip of tinfoil  $1/4$  of an inch wide, rising from the bottom of the glass up to within  $1/4$  of an inch of the upper rim, the lower ends of these tinfoil strips, or their ends, may be turned, being electrically connected with vertical knob-tipped metallic rods fixed in the centers of the outer glasses with a setting of plaster of Paris.

Lastly, from one of the upper corners of each of the field strips (these corners diagonally opposed on the field, strips touch each other in the apparatus) a narrow tinfoil extension  $1/4$  of an inch wide rises vertically to the rim of the glass over which it passes, and terminates  $1/4$  of an inch down the outside of the glass. On connecting the two balls at the top of the vertical rods with the opposite pole of a static machine, the central tumbler immediately begins a rapid rotation

which continues to increase until the apparatus fairly hums.

In starting, the foil sectors on the central tumbler are at first attracted by the charged foil strips within the outer glasses. As the sectors move into position opposite the field strips they receive sparks from the latter and become similarly charged, when repulsion ensues. Moving forward with the rotation of the tumbler they soon come within the influence of the oppositely electrified foil strip on the other side and are strongly attracted, until as they pass the field strips, their electrification is reversed and the cycle is repeated. The moving sectors receive their sparks from the tips of the field strip extensions whose lateral displacement prevents the electrification of the sectors until the latter have come opposite the exact center of the field strips. The "tumbler" motor is a fascinating little machine to watch in operation, and when one sees its vigorous rapid action it seems incredible that the motive power is static electricity. The instrument operates satisfactorily from a very small static machine.

## To Fill a Barometer Tube

By Henry H. Riggs

**A**MATEUR who have to fill or refill their own barometers are sometimes severely troubled by the redoxon air which will remain in the tube in spite of all precautions, and spoil the vacuum and the accuracy of the barometer.

The following will be found a very helpful trick, though it will not take the place of other precautions for keeping mercury and tube dry.

Take a piece of soft iron stove wire, and wind half a dozen turns around a large nail or rod of such a size that the coil will just slip inside the barometer tube. The coil must be a close one, with no space between the turns. Straddle in the rest of the wire, so that it lies parallel to the axis of the coil. Finally wind a piece of cotton yarn in the coil so that it lies snugly in the grooves between the turns of wire, bring one end through the coil and fit.

This makes a hollow mesh which just fits the tube snugly. After the mercury has been poured into the tube, hold the latter upright, mouth up, and slowly run the swab down to the bottom and up again several times. Any minute bubbles of air that adhere to the surface of the glass will be wiped off and carried away by this swab leaving the tube clean and dry and absolutely full of clean mercury.

## An Electrical Method for Glass Cutting

By Philip Edelman

**T**HE following method will be found useful for cutting off bottle necks, the ends of incandescent lamp bulbs, glass tubing, and similar pieces. Obtain a piece of the resistance wire, preferably of some non-ferrous alloy alloy such as is used in electrical heaters. A 100 ohm iron wire of the size which is used in the heater will be found satisfactory. Wind one turn of the wire around the part to be cut, taking care to insulate them at the point where they meet. Asbestos or mica will be satisfactory for this purpose. One turn is sufficient and should be sound tight. Now connect this short piece of wire in circuit with a suitable current. This may be A.C. or D.C. from a car run tap or from a battery. If a current tap is used a resistance should be connected in series so as to avoid a direct short circuit on the line. If a battery is used it must have sufficient voltage and amperage to heat the wire. Allow the wire to come nearly to a white heat for a short time and then plunge the glass piece into some cold water. Holding the piece under a water tap will assist. The glass should be broken cleanly at the point covered by the wire. The same general method can doubtless be applied to a variety

Cutting glass with electric heat

of uses. There seems to be a limit to the size of a piece which can be cut in this manner. However, the worker can now finish his flints and then use the method of the wire to break them.

The hot wire heats the glass in a restricted place which can be regulated by the worker as desired, and the heat does not spread all over the glass so as to cause an irregular heating. The glass coming into contact with the cold water is subjected to condensation strain at the heated portion and consequently either breaks or cracks.

# From Horse-Driver to Tractioneer

One  
Tractioneer = Sixteen  
Horse-Drivers in  
Efficiency

One Man and one Horse can handle 25 acres and no more. But one Man and a small Tractor can handle 400 acres. A Tractioneer, you see, is at least 16 times as efficient as a Horse-driver.

Or, if the Tractor delivers its power at the belt, instead of at the driver, one Tractor will equal from 30 to 50 Horses.

Now that wages are high, and horses are expensive, the Tractor has become the most valuable of all farm machines.

It enables one man to do 16 men's work, and at a lower cost.

One Tractioneer, with 2 to 4 gallons of kerosene, can plow one acre of ground. Such is the wonderful efficiency of the

This Tractor has solved the problem of Cheap Power for all farming purposes.

# Velvet

THE SMOOTHEST TOBACCO

"ES, there's a big difference in tobaccos and you can't always judge by the price. Velvet proves that. At ten cents a tin there's more real pleasure per puff than you can get out of the more expensive brands."

Velvet is smoked by particular people. It's just human nature that gives Velvet the preference. Velvet is genuine Kentucky Derby—well aged. This gives smoothness—smooth bits and horns. It also develops the foot evenly—the full, rich, delicious flavor, therefore, never varies. You've waited for such a smoke as Velvet—don't keep Velvet waiting for you.

Light Orange Flavor, etc.

Full 2-ounce Tin 10c Handy 5c Bags and one-pound Glass Hammer Jars.

of the car pass over them are located at intervals of 30 feet along the track, thus recording the time of passage of the car over each 30-foot section of track. Half second intervals are also recorded on the chronograph by connection through pendulum of a clock. The power consumed by the motor on the car is registered by a recording wattmeter, the chart of which makes one revolution while the car makes the circuit of the track. An electrically controlled pen in the time circuit of the chronograph records half second intervals on the edge of the chart. Thus the records of the chronograph and the wattmeter are co-ordinated. Air resistances in the tunnel are measured by a photographic recording water column.

## Progress of the Weather Bureau

THE annual report of the Chief of the Weather Bureau, just published, covering the fiscal year ended June 30th, 1912, while containing nothing of unusual interest, is a record of substantial progress in the meteorological work of the Government. The following items are especially worthy of notice.

As usual, the work of the Mount Weather Observatory heads the report. The scope of this institution has been somewhat enlarged, as it now serves as a school of instruction for newly appointed observers, who spend a few months here before being assigned to stations in the field. For five years past the observatory has been making daily observations of the upper air with kites and captive balloons, in all kinds of weather. The results of these observations, telegraphed to Washington, are sometimes highly useful to the forecaster at other times less so, hence the plan of making daily flights has been discontinued, and hereafter flights will be made only when there is a type of weather above the station that it is desired to explore. During the year three series of continuous kite flights were made for periods of 24 hours each, in order to obtain information concerning the diurnal variation of temperature at various altitudes in the free air. The Bureau has published a valuable digest of all the sounding balloon observations heretofore made in this country, viz., 70 made by the Mount Weather staff at certain places in the West, and 50 made by the staff of the Blue Hill Observatory. Studies on the relation between the temperature on mountain tops and that of adjacent valleys have been continued. There have been a practical bearing on the question of air drainage and its effects on fruit in the valleys.

Perhaps the greatest desideratum in meteorology is more knowledge concerning radiation from sun, sky and earth, and the Weather Bureau is doing its part toward supplying this need. The radiation received from sun and sky upon a horizontal surface is measured at Mount Weather by means of a horizontally disposed Callendar pyrheliometer. Direct solar radiation is measured with the pyrheliometers of Marvin, Angstrom, Callen and Åström, and polarization of sky light is observed with the Pickering polarimeter and the Nevart polariscope. The observations of polarization are employed in the study of atmospheric transmission ability, which not only varies with the weather from day to day, but also from year to year on account of causes not yet understood. All this is in line with the wide field efforts which are being made to find out how far the energy we receive from the sun, how the amount varies, and how this energy is disposed of by the atmosphere and terrestrial objects. On the answer to these questions depends the explanation of the principal mechanical phenomena of the atmosphere.

The Weather Bureau is co-operating with the University of Pittsburgh in the study of the mackerel problem, which course has meteorological bearings. Several contributions to pure sciences have been made during the year by the physicist of the Bureau, Prof. W. Humphreys, the most noteworthy being his explanation of the double diurnal fluctuation of the barometer.

The dream of the weather forecaster is to have at his disposal daily synoptic charts of the meteorological conditions over the whole world. Year by year the realization of this ideal is being approached. The synoptic charts drawn every morning in Washington have recently been made more complete by the addition of reports from Dutch Harbor, in the Aleutian Islands, Seward, Japan, and Shantung, and several stations in Asiatic Russia. Now the great question is to bring the coastal areas into the field by means of wireless reports from vessels, and the most important step in this direction has been achieved through the efforts of the Chief of the Weather Bureau, who as a delegate to the London Radiotelegraphic Conference last summer induced that body to agree to a regulation giving weather reports priority over all other wireless messages except distress calls. The Weather Bureau has already framed a tentative plan for a weather service covering the North Atlantic Ocean, and this will doubtless be put into effect as soon as European co-operation can be secured. In waters adjacent to the United States an effective wireless weather service is already in operation.

Other projects under way include an investigation of the mysterious "thermal belt" or "stratopause" of the Blue Ridge Mountains, experiments with devices for frost protection, especially early snow coverings, which is thought may be used not only for fruit trees, but also for vegetables and alfalfa, and, last but not least, a thorough experimental investigation of the errors of anemometers at high wind velocities.

## The Respiration Calorimeter

One of the most efficient and valuable aids to the investigation of the changes which take place when a chemical substance or a plant or an animal is observed under controlled conditions is the respiration calorimeter of the Department of Agriculture.

The first report of experiments with the respiration calorimeter was published in 1907, during the first year of Secretary Wilson's administration. Since that time numerous bulletins and other papers have appeared which have described the apparatus, noted very important modifications and reported the results of investigations. As time has progressed, the apparatus as originally devised has been greatly simplified and made easier of operation, and so developed that more factors can be determined than was the case at first.

The respiration calorimeter was designed and has been used for the study of problems concerned with the food and nutrition of man and animal, the value of different foods as sources of energy for muscular work, and other similar questions. It has recently been adapted to the study of fruit-ripening and other problems of vegetable physiology, and is equally useful for the study of a great variety of other problems, as for instance, questions of ventilation of houses and farm buildings.

The experiments with the respiration calorimeter have furnished new facts and figures of great importance to students regarding the processes of respiration and accurate information regarding the energy which man needs to run his body machine and the effects upon his energy requirements of sleeping and waking, rest and work and other factors. It is therefore possible to discuss such questions on the basis of accurate measurements, and this was not hitherto the case. The question of the energy which man expends to digest and assimilate his food has also been studied.

A deduction of great theoretical interest obtained with the respiration calorimeter experiments is that the rate of consumption of energy holds in the animal body. Such a conception is at the basis of many important deductions regarding nutrition and diet and the use which man makes of his food and farm animals make of feeding stuffs.

The human body is a complex machine.

Sixty-Ninth Year

# SCIENTIFIC AMERICAN

## for 1913

**A**S WE go to press for the first issue of the 69th year of the Scientific American we should like to be able to publish an approximate table of its contents for 1913. Although this may be possible for some journals, with the Scientific American it is obviously out of the question. As stated at the head of our editorial columns "The purpose of this journal is to record accurately, simply and interestingly the world's progress in scientific knowledge and industrial achievements." Scientific knowledge and industrial achievements are undergoing phenomenal developments, the progress of which will be chronicled in these pages. But what these developments will be who can foretell? So, in forecasting the Scientific American of 1913 we can only refer back to the year just past as an index of the manner in which the subjects for the coming year will be treated, and as a measure of our own development, we invite comparison between the Scientific American for 1912 and that for 1911.

Although a table of contents is now out of question, we are able to announce a series of subjects that will come in for special attention. These will appear in special magazine numbers which will be continued this year, as they have been in the past two years. The list of subjects is indicative of the broad scope of the paper, which concerns itself on the one hand with the vast powers of nature, and on the other with the minute micro-organisms of bacteriology, the great agricultural operations made possible with modern machinery.

In the following list of magazine numbers it should be understood that the subjects given out will not monopolize the whole of the number, but each number will contain the same variety of subjects as do the regular issues of the Scientific American.

### Motor Number

JANUARY 11

NEXT week the Scientific American publishes its fifteenth annual motor number. This unlike the other magazine numbers will be wholly devoted to the subject of the automobile and the motor truck. Topics of special articles are Automobile Bodies, Past Present and Future, Partnership Ownership of a Car, Kerosene Engine Carburetors and Converters, How to Realize Economy with a Motor Wagon, Left side Steering and Central Control and the Capabilities of the Motor Truck and the Horse Compared. There will also be a valuable table classifying all American made cars according to price, showing what cars can be bought for \$500 \$1,000 \$1,500 etc.

### Agriculture

FEBRUARY 1

FOLLOWING our practice of the last two years the February number will take up the subject of agriculture giving the latest information on improved agricultural machinery and the scientific treatment of soils.

### Water Supply

MARCH 1

THE tallest building in New York towers 750 feet above the ground—the deepest hole sinks as far below ground giving access to the Acqueduct Tunnel under the East River. Although the aqueduct has been described from time to time in the Scientific American it is hard to give an adequate idea of the greatness of this engineering undertaking. In our March issue a general survey of the whole aqueduct will be given.

### Harnessing Nature

APRIL 5

COAL will not last forever. What shall we do when it is gone? Of the great powers of nature we have succeeded in harnessing so far only those of the wind and the flowing stream, but there are open to us still the enormous power of the waves and the energy that the sun is constantly sending us in the form of light and heat. Many efforts have been made to utilize wave power but so far with little success. Just what has been done will be fully explained in the April issue. Also there will be an article on the utilization of sun power in which line some very promising experiments have been made.

### Safety in Travel

MAY 3

IT is time for radical improvements in the conduct of railroads. It is time that the automatic stop for trains was adopted not to relieve the engineer of responsibility but to act as a check upon him and to come into operation only in case of a lapse on his part.

### Bacteriology

JUNE 7

THIS issue is taken up with the greatness of the infinitely small. It will explain how some micro-organisms are our enemies and others our friends and how we may make alliance with the latter to war upon the former.

### Compressed Air

JULY 5

NOT a steel building, not a bridge, not a tunnel of any description has been built in the city without the use of compressed air. Why should the power be used in place of electricity? The advantages of compressed air and the peculiar conditions requiring its use will be explained in the July issue.

### Electric Furnace

AUGUST 2

IN the mass we shall deal with the electric furnace as used not in the manufacture of steel but in the laboratory where the intense heat it furnishes permits of chemical operations that enable us to reproduce artificially nature's own work in manufacturing diamonds, precious stones and other valuable products.

### Waterways

SEPTEMBER 6

IN the number we are reminded that we must not be so engrossed in the Panama Canal as to forget the important waterways in our own immediate neighborhood. The Cape Cod Canal the Canadian canal, harbor improvements, the widening and deepening of our navigable streams etc.

### Paper—Its Use in the Arts

OCTOBER 4

THE subject which is to be taken up in this issue is full of great interest. Not many realize to what extent paper and wood pulp enter into the arts, to suggest the various uses here would be to spoil the coming story.

### Great Inventions of Our Time

NOVEMBER 1

ALTHOUGH all important inventions are described in the Scientific American there are some that stand out above the rest and that are of an epoch-making character. These will come in for particular attention in the November issue.

### Panama-Pacific Exposition

DECEMBER 6

THE last magazine number of the year will be devoted to the Panama-Pacific Exposition and the opening of the Panama Canal to ocean service, which will mark a new commercial era for the United States.

The subjects referred to in the magazine numbers will be written by specialists in their several departments. Although we have made special detailed reference to those numbers it must not be inferred that all the interesting material will appear in them. The regular weekly numbers will contain the same variety of matter that they have in the past and we shall by no means follow the policy of using the best for the magazine numbers.

**STUDY** the illustrations! They show how you can double the efficiency and profit of your heavy service truck.

The upper cut shows the "traction" wave always formed in the ordinary continuous tire under heavy load. This wave, caused by the bulging of the rubber, works into the base and tears the tire from its fastenings. It can't be avoided in any ordinary way. Then, too, this wave forms a constant hill—the tire is always climbing, retarding progress, reducing power efficiency.

Showing traction wave in ordinary continuous tire (A) indicates where wave forms. (B) indicates base where roll and tread separation occur

Contrast this condition with the profit-making worth of—

# Firestone

**Continuous Base—Notched Tread**

## Truck Tires

The lower cut shows how the Firestone Notched Tread overcomes the wave, by preventing its formation. This is *not* an individual block tire, with tread-tearing, metal-retaining plates. The Firestone continuous base is of the same tough, resilient compound as the tread. These tires hold the road, increase traction, absorb all vibration.

Get the full facts. They mean Economy and Increased Profits

**Firestone Truck Tires for Every Type of Car, Every Load, Every Road Condition**

The Firestone Line of Truck Tires has in it the tire, solid or pneumatic, you need for your particular service. Get the books which tell the story. Ask, as well, for Quick Removable Rim facts. They are valuable.

## America's Greatest Touring Cars are Premier Sixes The First of the Five Leading Makers to Establish the New Price Basis for the Six was the Premier

**T**HE public has decided that the high-class car of the future must be a Six. The Premier is one of the four makers whose six-cylinder cars have created this six-cylinder demand. Seven years' production of successful sixes.

The Premier six-cylinder is not only a leader in price but in style and appointments. It is fitted with pneumatic starter pneumatics, the inflator independent elec-

tric lighting system, imported magnesium imported annular bearings, left hand drive, electric running boards, a cabinet mounted in the dash providing a tool carrying compartment, gasoline fed by gravity with filling cap accessible without removing the cushions, luxurious upholstering, Turkish cushions, concealed hinges, and straight line bodies, finished with the pleasing touches which make for elegance and class.

### **Premier Sixes, \$2735 to \$4000**

FULL TOURING CAR EQUIPMENT

The Premier has earned its position as one of the leaders among America's leading cars by its wonderful performance and successful showing in the most trying tours and contests each year.

The first of the five leading makers to establish the new price basis for the six was the Premier. Its name which preceded the standard with the Premier Sixes, is the first.

## Four years ago we recorded a prediction

### The Prediction

Reproduced from Cadillac advertisements of December 1908

Ultimately the Cadillac will find its way into the hands of hundreds of owners who have heretofore paid twice and thrice as much money.

The deep rooted conviction which these men naturally cherish—that there must be something lacking in the Cadillac to make such a price possible—is one which the Cadillac Company is eager to encounter wherever it can be found.

To meet and defeat that impression by practical demonstration during the ensuing season is of vastly more importance than the mere matter of sales.

The latter problem has been disposed of by a demand from dealers which has exhausted an output of ten thousand cars, and driven the factory to exert its fullest continuous capacity night and day.

Of infinitely greater moment, as affecting the well being of the Cadillac Company a year from to day, and ten years thereafter, is the establishment of the principle that a high powered car, of the highest grade can be built to sell at a popular price.

Stripped to the chassis and subjected to the jealous scrutiny of experts in material and in mechanics matched part against part down to the last detail with cars of known integrity sold at the highest market figure, the Cadillac will prove beyond question that such a car can be built at such a price.

But your investigation, proving that the Cadillac Company has made the impossible possible by heroic means and methods will likewise demonstrate this that:

HIGH POWERED CARS EQUAL TO THE WORLD'S BEST CAN BE BUILT TO SELL AT A POPULAR PRICE IN ONLY THE ONE FACTORY WHICH IS FITTED BY EXPERIENCE AND EQUIPMENT TO UNDERTAKE THE TREMENDOUS TASK.

Four years ago we foretold in our advertisements as reproduced in the appended column, that—

Ultimately the Cadillac Motor Car would find its way into the hands of hundreds of owners who had theretofore paid twice and thrice as much money.

You must be conscious that the prophecy is being fulfilled; that the "hundreds" predicted is being realized in "thousands."

The prediction was not made in a spirit of vainglory. Nor is its realization recorded now with any special sense of elation. But the simple fact is interesting, and highly creditable.

Creditable, we mean, to the discernment of the American business man.

It is not easy to resist the glamor of the highest dollar mark.

It is not easy to believe that equal or greater excellence can be found at a lower price.

But that is precisely what has happened in the case of the Cadillac. We felt four years ago that it must happen.

We were sure that no manufacturer could have higher ideals, or adhere more rigidly to those ideals.

The basis of a car's worth, of course, is the engineering practice and the factory practice which govern its construction.

That is the first excellence you strive to obtain when you pay the highest price.

And that was precisely the point in which the Cadillac was awarded world's precedence by the Royal Automobile Club of London.

We knew that in practice—close measurement, standardization, alignment, proportion—the Cadillac was not an aspirant but actually a leader.

We knew, in other words, that it was not surpassed, and that it was not even equalled in that respect.

And we knew, too, that that which went into the car could not be better.

We had no thought of emulating cars of higher price.

We were wholly engrossed in making the Cadillac the best of cars. So, the fact that our prophecy has come true is an incidental, although an important result.

It has happened because we began with the positive conviction that—given a production of adequate size—no higher price than the price of the Cadillac was necessary for the highest type of motor car.

Surely your own Cadillac experience, the experience of every Cadillac owner in your community—and, indeed, of every Cadillac owner you have ever met anywhere in the world—justifies it.

The Cadillac is now the choice of thousands who were once wedded to cars of the highest price.

They have abandoned the recognition of the dollar-mark as the symbol of highest value.

It is one of the most interesting things that have occurred in motor car history—one of the most significant signs of enlightenment in buying that has occurred in latter-day America.

#### STYLES AND PRICES

Standard Touring Car, Six passenger		\$1975 00	
Six passenger car	\$2075 00	Runabout two passenger	\$1975 00
Phaeton, four passenger	1975 00	Coupe four passenger	2300 00

CADILLAC MOTOR CAR CO., DETROIT, MICH.

# Electricity's Part in the Automobile

## Electric Lighting

Photo H. W. G.

The gasoline car is dependent on its electric spark the electric car upon its storage batteries.

When lighting up time comes safety is in a large measure due to a dependable lighting system and satisfactory lamps.

On all representative cars **Edison Mazda** automobile lamps have been adopted as standard. Due to the large volume of light given by **Edison Mazda** lamps for comparatively little current, electric generators and batteries were made small and light enough to be incorporated in the equipment of the modern, up-to-date car.

The General Electric Company was not only the pioneer in the development of automobile lamps, but is today the largest manufacturer in the world of this type and of every other type of incandescent lamp.

This company is in the closest co-operation with car builders and makers of electric lighting systems—the result therefore is the most efficient lamp for all conditions of automobile service—the **Edison Mazda**. This lamp has a strong sturdy filament made from drawn tungsten wire. In connection with electric lighting a number of wiring devices are made which facilitate connecting and disconnecting lamps for permanent or portable use. The switches which control the lights also bear the hallmark of quality of the largest electrical manufacturer in the world.

Three Terminal Lamp Socket H. W. G. Co.

## Electric Motors and Controllers

It is a real pleasure to step into a luxuriously fitted electric carriage, and by the movement of a single lever apply and govern the propelling force. Nothing takes the mind from the fullest enjoyment of the ride.

Starting out in evening clothes, without a chauffeur, one can be sure of arriving at his destination with certainty and an unruffled temper if the car is equipped with a dependable power plant, furnished by the General Electric Company, such as has been adopted by electric car builders of the United States using more than 65% of all the electric vehicle motors built.

This power plant is so unobtrusive and demands such infrequent inspection or adjustment, that its presence in the vehicle may almost be forgotten.

The motor of an electric car must be efficient and light in weight. This is to give the greatest possible touring radius on a single battery charge and thus preserve the life of the storage battery, which is dependent upon the number of times it is discharged.

Automobile motors made by the General Electric Company meet all these conditions and in addition absolutely prevent over discharge of the battery on steep grades.

The electrical design of the motor assures the best operating characteristics as well as embodies many important novel features which have made G-E motors pre-eminent in the world's haulage today.

The weight of the motor is reduced by the use of aluminum wherever possible and great strength is obtained by making the frame and head of a single piece cylindrical steel casting, machined from end to end.

The controllers made by the General Electric Company are of the continuous torque type securing smooth acceleration and deceleration under all conditions. In both mechanical and electrical design they use the same features which have made G-E street car controllers the standard of the world today.

Because of the above reasons more than 65% of the electric motor and controller equipment

Automobile Motor, a view from a side.

Automobile Controller, Three Type.

used by automobile manufacturers of the United States is of G-E manufacture.

Many merchants who require absolutely dependable delivery service are using in the aggregate hundreds of electric trucks. Records show that these trucks are in use more days each year than any other kind of delivery vehicles and that their upkeep is much less.

These trucks climb the steepest hills in deep snow or plow through heavy mud with equal ease and certainty.

## Electric Charging Devices

When Electric Automobiles were first introduced one of the most serious inconveniences connected with their use was to get the batteries charged.

This difficulty has been removed by the invention of the Mercury Arc Rectifier, an inexpensive, easily operated device for changing the alternating current of the ordinary lighting circuit to direct current suitable for charging storage batteries. With a Rectifier installed in the private garage the car does not have to be sent to the public garage for charging and is always ready for use. The General Electric Company makes a small rectifier known as the "Runabout" type, which has just the right capacity for charging the batteries of electric pleasure cars.

When the current supply is from an electric railway circuit, a motor generator set is used in place of a rectifier, but where direct current lighting circuits are available, as in the downtown district of New York City, charging rheostats are all that is necessary.

In all cases the convenience and usefulness of an electric car greatly increased by reliable equipment for home charging.

The foregoing shows the many advantages due to electricity in its application to the automobile.

Wherever that silent power called electricity is used, there will be found skilled engineers, backed by the wide resources of the General Electric Company, perfecting the product—making the G-E monogram stand for the "guarantee of excellence of goods electrical."

## Grauling Tests for Artillery

By Our French Correspondent

**T**HE Krupp establishment is making use of some very efficient endurance or breakdown tests upon artillery both for keeping up a check upon the standard types of pieces and for testing new designs. One of the most novel methods is the use of a circular electric testing track upon which a car is run in order to draw the artillery pieces over the ground at slow or high speeds as may be required.

At the Dagen artillery grounds which lie near the main factories there is laid out a circular railroad track with a special kind of electric car running upon it for making the tests upon the artillery. The track has 210 feet mean diameter which gives it a total length of about 660 feet. It is substantially laid on beton and, using a single rail on the outer side and a double rail on the inner track, so as to keep the car from running off the track. The railroad track proper is usually reserved for the electric car while the artillery is run on a circular way which lies on the inside and also on the outside of the main track thus allowing two pieces to be drawn along at the same time. The artillery track is slightly banked. The railroad track has a 7 foot 6 inch gauge and if desired the artillery can also be run in the space between the rails. In order to vary the tests the nature of the ground is made different upon various parts of the circular tracks. For instance, some 60 feet of the track is about half the circle is laid with a good stone paving while the remainder represents country roads in more or less good condition. Upon these different stretches of road there can be placed obstacles of various kinds such as timber lying across the road and ditches or holes and the like. The use of the electric car for drawing the artillery has an advantage from the great number of different running speeds which can be employed representing what a team of horses would give at a trot or gallop and much higher speeds can be used when desired.

On the upper floor of a cabin is an inspection room which serves for engineers or official committees when making certain tests upon the artillery whence the track can be overlooked. Signals can be sent from the track into the cabin in order to give notice to the operators and when in this use there are placed six signal posts around the track so as to send electric bell signals to the cabin during the maneuvers for changing speed or stopping and the like. Across the car is a bar to which the tongue of the artillery piece can be attached so as to run it on the outer middle or inner track. The car is started up and the piece is taken around at the different speeds which may be required for any given case so that it will be seen that the electric track allows any such maneuvers to be made very quickly and avoids loss of time. As regards the obstacles which are put in the way of the artillery piece to give it a severe endurance test one of our correspondents shows a field howitzer taking over a heavy piece of round timber and at a high rate of speed. Seeing that the artillery piece springs up to a considerable height and then falls on the ground and that its total weight is 24 tons, an idea of the good quality of the axle and wheels will be obtained. Another illustration represents an ammunition wagon

Electric motor dragging an ammunition cannon through a hole with steep sides

A test over prepared roadway composed of large stones and boulders.

Recall siege cannon upon carriage drawn by horses clearing a wooden obstacle at the testing ground of Tanagerhite

Two field guns and their fore-carriages drawn by a steam locomotive over obstacles consisting of railway rails

Testing track at Ennon. Field mortar clearing a road leg placed across the track

being drawn at a high rate by the car and passing over a steep ditch dug on the track at this point. It is so laid that it is stated that the track is well lighted by arc and incandescent lamps. Up to the present time the tests which cover a period of several years are not to be much as 40,000 miles run up on the circular track.

Some very severe tests of another kind are obtained by the use of steam locomotives running on a special stretch of railroad track at the company's artillery grounds at Meppen. At each side of the track is laid out a paving way containing surfaces of varied character or special obstacles. Our engraving shows two artillery pieces attached to a crossbar, each running on a separate way. Here the road is made up of heavy broken stones. When the locomotive is run at high speed this gives a very severe test and in some cases the artillery pieces jump high from the road to a considerable height. This is the case in our present figure where the obstacles consist of railroad rails laid crosswise and spaced along the way.

Other endurance tests of artillery are made upon actual roads in the country using a team of horses as one of our photographs shows. The field piece is here passing over a very high obstacle formed of three logs laid together and it strikes a conspicuous height off the road.

## Showing Visitors How Cars Are Made

**S**OME of the latest saving devices which have been described in a recent issue of the Scientific American will be shown to the visitors of the New York automobile show in Madison Square Garden. Several typical multiple production machines will be exhibited in operation at turning out standardized parts at the same number as it is done in the large automobile factories. This part of the exhibition will probably draw larger crowds than the more show of the cars, for it will show the way in which the things are done.

## Automobile Accidents in Paris

**A**CCIDENTS due to automobiles are becoming more frequent in Paris owing to the development of the taxicabs and auto buses. The official figures for last July show a total of 170 accidents during the month of which the taxicabs are responsible for 50 accidents with 2 deaths. For the auto buses there are 11 accidents with but 1 death. The tramways have for 20 (6 deaths) and private automobiles make up the remainder. It will thus appear that the automobiles are not responsible for as many accidents as might be thought and the complaint made by the public appear to be unfounded.

## The Automobile in Egypt

**T**HE use of automobiles is becoming quite extensive in Egypt within a recent date especially at Alexandria and Cairo. The latest figures show as many as 265 cars registered at Cairo although all of these are in circulation. It is estimated that at least 400 are in regular use and these are running almost entirely within the city. Outside of town there are but few roads such as the Pyramids, Helwan and the Helwan routes. At Alexandria there are about 100 automobiles. The only good road outside the city is the Nile route leading to the resort of San Stefano.

Congress saw fit to establish our model experimental basin at the Navy Yard in Washington. Let us trust that the same legislative wisdom will provide a national aerodynamic laboratory. The cost will be modest, but the results will be invaluable.

## Electricity

**Electrically Operated Suspended Railway.**—A novel way of mountain climbing is provided in the new electric suspended railway on the Kohlenberg, in the Tyrolean Mountains. The suspension cables, 5,600 feet in length, are carried on twelve towers, and two cables on each accommodating fifteen passengers, and two cables are operated, one being hauled up the hill by duplicate traction cables while the other is descending. Complete safety appliances are provided, and a magnificent view is opened out as the cars ascend smoothly up the 2,700 feet from the Rissack in thirteen minutes.

**Picture Telegraphy Across the Atlantic.**—Although the Berlin scientist, Dr. Korn, is having good success in sending photographs by wire between stations located at Paris, Berlin and Monte Carlo for use in press work, he wishes to apply his method over a much longer distance. In fact, it is possible to send the photographs by mail between Paris and Berlin, for instance, in a comparatively short time, so that the newspapers are not so likely to take up a picture-transmitting scheme as when they are a long distance from the center of events. For this reason he expects to take up the question of operating upon the Atlantic cable and is confident that he will be able to send photographs by wire from New York to London, and considering the matter of coming to America in order to apply the system to a line between New York and San Francisco. We illustrated this apparatus not long ago.

**Electric Stage Service Across the Alps.**—Quite an extensive project is being organized in Switzerland for an electric automobile service across the Alps. The cost of improving the roads and purchase of material is about half a million. The line runs from Airolo by way of the Bedretto valley and the Nufenen pass, ending at Urikeren in the Valais. The line is 117.700 feet high, and 145 miles. Considerable work will need to be done in enlarging the routes so as to make them suitable for automobile traffic, and a bridge is to be built over the Trossa River. The new electric automobiles have capacity for 32 passengers and make the trip in 2 1/2 hours. The ordinary and 134 on express service, running at 12 to 22 miles an hour. There are eight to ten stations along the route and three trips are made per day in each direction, during all seasons when there is no snow on the roads. A great advantage is predicted for the electric service.

**How a Paris Central Station Gained by the Change to Greenish Time.**—The fact that Paris adopted Greenwich time not long ago causes an electric-light station to gain \$20,000 a year, according to an estimate recently made for this purpose for the city of Paris. It is a difference of time of burning electric lamps and even though this is very small, it figures up in a yearly estimate to quite an extent. Greenwich time of 5 o'clock corresponds to 5:10 Paris time, for instance. Lamps are on for an amount of time less than they would be if the clock at a fixed hour. Should an office close at 6 o'clock, it is evident that the lamps will have burned 10 minutes longer owing to the change over to Greenwich time. The extra amount of current is naturally paid for by the city, so that this makes the central station plan about 1 per cent, and even this small difference applied to the case of an electric plant furnishing 10,000,000 kilowatts a year, will give the above increase.

**Cableway to the Col du Midi.**—A suspended cableway is now building on Mount Blanc and it will reach the elevated point of the Col du Midi, which is not far from the summit. It follows somewhat the general lines of the Wetterhorn cableway and like the former it is designed on the Crest-Tanfay system. The terminus of the cableway is on the Col du Midi, 11,770 feet high, this being somewhat below the well-known peak of Aiguille du Midi, (12,000 feet), but the latter was rejected in favor of the former owing to lack of space at the peak to make a large landing place. The car hangs down from a roller carriage traveling on a single main cable which is stretched along the route upon structural iron towers. There is an upgoing and a downgoing car as in a cable incline, the car being drawn along by a cable working upon sheaves at each end. What is novel is the use of an extra cable running along under the main cable and passing through the carriage. Usually it runs idle, but should the main cable break, it then serves to support the car, being by a set of rollers as to take the place of the former and the car still runs on the main cable. On the other hand, the extra cable now serves to draw the car into the station, thus playing a double part in accidents. The line is about 3 miles long in seasonal periods and starts from the Pölen station at an altitude of 3,600 feet. The mountain peak of Col du Midi 8,200 feet higher. The lower end lies near Chamouni, and the railroad runs quite near this point. It is laid out in four sections to avoid using too long spans, so that the stations where the cables are strung are at a length of span allowed is 8,000 feet on account of the strain on the towers. The second station is in Le Praz and the third at Bonneville. It is proposed to run the automatic service to bring tourists from Chamouni to the lower station. One section of the cableway is nearly finished and the whole will be running in 1918.

## Science

**The International Union for Solar Research,** which met on the Mt. Wilson, Cal., in 1917, will hold its next meeting at Bonn, beginning August 1st, 1918.

**An Crystal-shell Building.**—A five-story concrete building, the concrete being made of crystal shell from the reefs of Galveston Bay, has been erected at Galveston, Texas. The owners of the building and its constructors, Nicholson and Theobald, claim this material is better and cheaper than concrete made with gravel. Shell concrete was built into a wall 3 feet high and 336 feet long in 1902 withstood the severe test of fire and water and is to-day as sound as when built. It is estimated that the shells of 5,000 crabs are imbedded in the walls of this building. This is said to be the only building of its kind in the world.

**The British Association for the Advancement of Science** will meet in Australia, for the first time, August, 1914. The Association has met three times in Canada, and in South Africa, but all the other meetings have been held in the British Isles. The coming meeting will include sessions at several towns. The Commonwealth government has appointed a federal council to arrange for the meeting, under the patronage of the government, and will make the arrangements as chairman, and has granted £15,000 to pay the passage of Australia of not fewer than 150 official representatives. A number of foreign men of science will be included in this number.

**Effects of Indol in Producing Symptoms of Scurvy.** Some interesting experiments as to the effect of the chemical compound indol in producing scurvy have just been conducted by a pupil of Metchnikoff. Indol is one of the toxins secreted by intestinal bacteria, and Metchnikoff has claimed that it is responsible for certain symptoms of scurvy. In the experiments referred to above 0.04 gram of indol were injected into guinea-pigs. Not only was scurvy of the scurvy character, but the liver, kidneys, and suprarenals were affected and there was a tendency to hardening of the brain. Since these are all symptoms of scurvy, Metchnikoff's theory seems thus far supported.

**The Electrical Resistance of Trees** has been the subject of some elaborate experiments by T. E. Stone and C. H. Stone at the Massachusetts Agricultural Experiment Station. It was previously known that tree piths possess relatively high resistance—an important quality as serving to protect them from lightning—and that the resistance varies for different kinds of tissues. Messrs. Stone have determined a law governing the resistance, the fact that the resistance varies markedly with the temperature, being higher with a low temperature and lower with a high temperature. This fact results in a diurnal and an annual variation in the resistance. The outer layer shows the least electrical resistance. This is followed by the phloem and then the pith.

**Aeronautical Weather Station in England.**—The British Meteorological Office has arranged to operate a branch of its service at the Royal Aircraft Factory, South Farnborough, for the purpose of supplying meteorological information and forecasts in a form directly applicable for the guidance of aeroplanes, and also for carrying on investigations of meteorological problems for the Advisory Committee on Aeronautics. Mr. J. S. Dines has been appointed meteorologist in charge. The equipment will include pilot and sounding balloons and laboratory instruments in addition to the ordinary meteorological apparatus. Special forecasts and warnings for aeroplanes will be issued on the basis of information telephoned from the Meteorological Office at South Kensington.

**The Economics of Mountain Snowfall.**—The attention of American meteorologists has been directed in recent years to the importance of the winter snowfall on the mountains of semi-arid western states as a source of the water available for agricultural purposes or for motive power the following summer. A dual problem has been thus discovered: (1) the development of methods of measuring the volume of snow lying on the mountain slopes, as a means of predicting the amount of water it will yield, and (2) the conservation of the snow by appropriate treatment of the forest cover. Among the interesting discoveries made in this connection is the fact that the ideal forest for snow conservation is one filled with glade woods, whose bare shrubs proportion to the height of the trees that, while snow enters freely, the wind and sun reach easily by bottom. The production of such glade by cutting and pruning, as well as by planting trees of suitable species (e. g., the mountain hemlock), becomes, therefore, a part of forest practice in the regions in question. Aside from investigations by the Weather Bureau and the U. S. Forest Service, the subject has been most actively studied by the excellent meteorological department of the University of Nevada, which is now planning to offer a special course for foresters on the relation of mountains and forests to the conservation of snow. The University of Nevada is the well-known meteorological observatory on Mount Rose.

## Automobile

**International Automobile Shows.**—Inter-billions of automobiles have been planned, 11th to 22nd, in Brussels, Belgium, and for the months of March, April and May in Vienna, Turin, Budapest, St. Petersburg, Berlin and Stockholm.

**The Pocket-knife Basket.**—If a way of killing two birds with one stone, so to speak, an enterprising accessory manufacturer has developed an automobile lunch basket which serves a dual purpose in that it is a footstool as well. The basket proper is made of wicker-ware and is fitted with the usual knives and forks, cups and saucers, etc., with a slatted space for the storage of food. The top is slatted and strong and is covered with leather to resist wear. It is designed to be placed in the tonneau.

**The Deep Cushion.**—Just where the deepening of cushions will end, unless it ends on the floor of the car, no man can tell at present. When ten-inch cushions were advertised as the sign of perfection, an enterprising manufacturer immediately announced twenty-inch upholstery and two more lately have gone to the length of providing cushions no less than fourteen inches in thickness. The saving grace of an otherwise ludicrous situation is that the deepening of cushions in general has had a distinctly beneficial effect—for the car owner of course.

**Greatening at Speed.**—Demonstrating the deepening of speed judging by sight alone the results of a test recently held by a British automobile club are interesting. Several motor cars were run up on an unfrequented road and required to estimate the speed of a car driven at a predetermined rate with the aid of a speedometer. Out of four trial runs at various speeds only two speeds were guessed by one person correctly. The others varied from the correct speed by more than 10 per cent to emphasize very forcibly that it is practically impossible without extensive practice, to judge of the speed of a car merely by watching it pass.

**"Clean Design" is Cars.**—There are no kinks no corners not gabbling projections at dash or elsewhere. It is a well-known fact that an automobile is a machine to public notice has latest creation. Which briefly, is exactly what the present American car is. Never before has the striving for "clean design" been so apparent in American products. Unusually tight boxes which heretofore have been the rule have been replaced by the "bleeding" of lines at dash and at tonneau in a marked contrast to the angles and generally unfinished appearance connected with the adoption of front doors.

**The Long-stroke Motor.**—Imported from abroad when it found its way into the United States, the long-stroke motor is apparent in the popularity of the long-stroke motor. From a conservative middle ground, manufacturers apparently are getting to the extreme in stroke to increase the volume of the motor. The motor has been developed. Among the latest developments announced for the coming season, are two motors from the same manufacturer one of which measures 3 1/2 x 6 and the other measures 4 1/2 x 7. It is true that motors with even longer strokes than these have given a measure of success abroad and they therefore cannot be viewed wholly in the light of experiments. Time only, on the road in the hands of owners can tell just how much the designer has bettered existing conditions by his plans.

**The Filled Tire.**—It is radically, almost continuously, the filled tire, which is the latest in the automobile world which is expected to replace the air in pneumatic tires makes its appearance, floats for a moment in the public eye and then fades away into the future. But it must not necessarily be assumed that such will always be the case and that the pneumatic tire will continue to be obtained. The repeated recurrence of the idea shows the existence of a latent demand and it is quite within the bounds of possibility that the demand may some day be filled. Already there are several such compounds on the market which are made in the same manner as the pneumatic tire, and their manufacturer, or compounder, would seem to have eliminated many of the difficulties which at first were experienced with everything that was supposed to take the place of air and handle the troubles for it.

**Wire Wheels.**—Despite the fact that the automobile undoubtedly has needed a not worthy means of efficiency and dependability there can be little reason to suppose that finally of design has been reached. There are few manufacturers who have not something new to offer either in the way of equipment or design and it is slightly altered still further to increase efficiency and to reduce the small amount of physical labor necessary in the operation of any car. More than ordinarily prominent among the changes which will be evident in the car of 1918, and which are such as to make the car more easy in design, is the widespread movement in favor of wire wheels. Already more than a score of manufacturers have specified wire wheels as optional equipment and three or four have taken the bull by the horns, in a number of special cases, and specified wire wheels as standard equipment, with wooden artillery wheels optional.

In outward appearance the "car of the future" resembles a submarine boat more than it does a carriage. Its long cigar-shaped body incloses everything except the wheels, and even they are covered for almost half of their diameter.

## The Future Car

### How Car Bodies Have Developed at Home and Abroad

By Walter Bunnard

*In automobile designing as well as in political movements coming events cast their shadows before them. If we would visualize the car of the future, we have only to study the car of the past. That is the object of this article. In order to obtain a correct impression of the automobile of the future, the author has presented and criticized both the European and American cars designed during the last twelve years.—Editor.*

Fig. 1.—Car built for the German Emperor in 1903. It had a rear entrance, proof that the problem of efficient mudguards and running boards had not yet been solved.

Fig. 2.—A car designed for the German Emperor in 1905. There are still unmistakable signs of the carriage maker's hand.

Fig. 3.—The German Emperor's 1907 car. Although it would not attract much attention to-day, the seat backs are stiff and vertical, the upholstery hard and thin. The driver has no protection.

Fig. 4.—A touring car of 1909.

Fig. 5.—A splendid car built in 1910 for the President of France. Fore doors appear for the first time.

Fig. 6.—A 1912 model, which, were it not for the presence of the tool box in the very middle of the running board, might be considered more beautiful than the graceful car shown in Fig. 7.

Fig. 7.—A 1913 German model, a good example of neat designing.

Fig. 8.—A 1906 American limousine.

THAT the first automobile bodies were in all respects nothing but adaptations of the older carriage bodies is fairly well known. Many of the readers of this periodical will remember the first cars of a dozen years ago, and their awkward appearance. They were the product of a compromise—and like most compromises, were very unsatisfactory. That the motor-driven carriage was a thing apart and different from the horse-drawn rig early became evident to thoughtful designers of automobile bodies. But while they well realized the necessity of striking out in different directions, they were not at all anxious to make radical innovations. The conservatism of the majority of the human race resents upheavals of any kind, preferring rather a gradual elimination of the undesirable. The change from carriage body to automobile body therefore had to be made slowly, and at the present time we have about arrived at the half-way station. The automobile of the future will look no more like the motor car of to-day than the limousine of 1913 looks like the *dos-a-dos* of 1906. The limousine or torpedo touring car of the present year is but a link in the gradual transformation of the horse-drawn buggy into the completely enclosed, dust proof, silent and comfortable "car of the future."

In outward appearance the "car of the future" resembles a submarine boat more than it does a carriage. Its long cigar-shaped body incloses everything except the wheels, and even they are covered for almost half of their diameter. To the eye of the motorist of 1913 it may present too "squat" an appearance, owing chiefly to the low position of the body. The car has no running boards, no hood, no mudguards, no wind shield and no flapping top. The motor is carried in front of the driver, as in the ordinary motor car, while the various indicators are placed within easier reach of the driver's hand than is possible in the orthodox vertical or sloping dashboard arrangement. The curved plate-glass front of the body affords a clear view of the road ahead, while giving absolute protection from wind, dust and rain. Ventilation is achieved by narrow slits in the sides and top of the car. Conforming to the shape of the body, the doors are curved, reaching so close to the ground that an eleven-inch step is all that is necessary to enter the car. Ample space is provided in the rear of the hollow body for baggage and the carrying of spare tires and other parts, while the seating arrangements allow each passenger more room than he would have in a modern limousine, and far more than in the various seven-passenger models of the present day. Wind resistance and the danger

Fig. 9.—A 1907 American landaulet

Fig. 10.—The few changes made since 1907 caused many to think this 1909 model the "car of perfection."

Fig. 11.—An American 1911 model which will not survive because of its peculiar broken appearance.

Fig. 12.—This type of 1912 is objectionable for the reason indicated in connection with Fig. 11.

Fig. 13.—A coupé type of 1913, which looks odd because the hood and dash-cowl combined are longer than the car body.

Fig. 14.—A so-called brougham, designed in America, in which it is difficult to pick flaws.

of skidding are reduced to a minimum in this design, and a number of racing cars constructed on these lines have proven that greater speed can be attained. The tendency toward "stream line" bodies is clearly evident although opinions differ as to the ultimate design which will be evolved. To assist the reader in forming his own opinion of what the car of the future will look like I am showing herewith types of body construction in chronological order from 1900 to 1915.

The cars shown in Figs. 1, 2 and 3 were made for the German emperor in 1900, 1905 and 1907, respectively, and therefore may be said to represent the best type of these years. The first two are "rear-entrance" cars, built in this manner chiefly for the reason that the problem of efficient mudguards and running boards had not yet been solved. They are clearly attempts at producing something comfortable and suitable for motor propulsion, and still suggestive of the carriage-makers hand in the design. The manufacturers of the chassis and motors were already striking out in new directions at that time, but the body builders were still hampered by the traditions of the carriage in design.

Fig. 3 shows a car which resembles the machines of to-day. It could be driven down Broadway in New York city without exciting sarcastic remarks among the pedestrians. But the backs of the seats are stiff and vertical, the upholstery is hard and thin and the driver has no protection from the elements and the dust.

The next illustration represents an immense step forward. It is a splendid car built in 1910 for the president of the French Republic by a firm which supplied Napoleon with the court carriages more than a century ago. It shows the fore-doors for the first time. When professional chauffeurs did the bulk of the driving of motor cars, no one gave much attention to their comfort and convenience, but as soon as the private owner began to drive the car himself the necessity of doors for the front part of the car became evident. A comparison with the preceding photographs shows a some of the most characteristic and pronounced tendencies of that year. The wheel base has grown longer, the steering column is set at a more "ranch" angle, the steering wheel is larger in diameter, the running boards are free from unnecessary boxes and litter of all kinds, and the whole car has more sweeping and pleasing lines.

Particularly graceful are the lines of the huge limousine shown in Fig. 6. Were it not for the presence of the tool box in the very middle of the running board, it might be considered a more beautiful car than the graceful model represented by Fig. 7. The cars were built in 1912 and 1911 respectively—that is to say, they are the leading models of these years. The sweeping curve at the rear of the top in the 1912 model is undoubtedly more pleasing than the sharp edge of the following year's type, but the usual outlines of the mudguards and hood, the lower steering column and especially, the clear running boards are advantages which the earlier model does not show.

The American automobile industry during these years kept fully abreast of its European rival. The same faults and drawbacks are noticeable in both but there are also in evidence all the little improvements that were added abroad, in addition to some that were invented on this side of the Atlantic. But for the peculiar construction of the body of the 1911 model in Fig. 11, which makes it resemble two independent carriage bodies, stuck together as a sort of afterthought there is no need of apology on this maker's part. The type is one which has a number of adherents, but which will not survive just on account of this peculiar "broken" appearance. In more exaggerated form it is shown in Fig. 16, which is a fine illustration of how an automobile body should not be designed. This style of construction is positively ugly—despite the fact that it may be comfortable and mechanically advantageous. The car also appears bigger than it really is, which may or may not be desirable, according to the opinion of the purchaser. The coupé type shown in Fig. 13 looks so odd chiefly on account of the extreme length of the hood, covering the six-cylinder motor, the hood and dash-cowl combined being longer than the entire body of the car.

It is difficult to pick flaws in the construction of the body shown in Fig. 14—a so-called brougham. The first view of this car impresses one with the immense power and speed possibilities lying within it, and subsequent closer examination only strengthens this first impression. It is a body design which is in no way inferior to anything produced in Europe, and shows the present high state of the industry in this country. The wheel-base of this car is practically thirteen feet.

An extraordinary European body construction is shown in Fig. 15. This type represents the latest idea in including everything within the outer lines of the body, presenting a perfectly smooth exterior and greatly reduced wind resistance. Not only are the running boards absent, but the

Fig. 15.—The latest European idea in including everything within the outer lines. Complete protection is afforded to baggage, spare tires and tools.

Fig. 15a.—Elevation and plan of car in Fig. 15

Fig. 16.—A French type of 1912, conspicuously ugly for its class.

Fig. 17.—A modern French roadster in which an attempt is made to obtain smooth lines.

Fig. 18.—A good example of present French tendencies.

Fig. 19.—A 1912 phantom which has a distinctive body suggesting speed and comfort

body itself hangs over the wheels, giving plenty of room to the six passengers. The car is by all odds the most radical innovation in the line of body design, and from reports from abroad is expected to be placed in commission during the coming season by at least one prominent foreign maker. The new body is built on an ordinary chassis at the last automobile show in Berlin Germany, and created a veritable storm of discussion and criticism. It is the most comfortable design that has as yet been evolved, and the complete protection it affords to the passengers were tires, foot levers, etc. is of great value to the long distance tourist.

French designers of peculiar shape are shown in Fig. 17 and 18 but a detailed description of their features is hardly necessary as an examination of the illustrations will disclose their possibilities.

The designing of bodies for motor cars is becoming more and more standardized. Only a few years ago body builders made a few special designs for each manufacturer and there were hardly any two of them alike. Then, too, the customer, particularly abroad, used to purchase his own bodies, made according to his preferences and ideas. The best example of this is the modest car or car which some time ago was built for a wealthy American body which actually was purchased as so to say by figure as closely as possible. While other automobile purchasers were not quite so particular as to just how the body fitted them, they did express preferences which the body builder had to consider. As a result a number of freak bodies are now running this country as well as Europe. In many instances their owners are heartily weary of looking at them.

A standardization in body design, therefore, is very desirable not only from an economical standpoint as also from the more altruistic one of beauty—as opposed to freakish and ugly designs. It is cheaper to build one thousand good automobile bodies after a time and the same design than it is to build one thousand mediocre ones after the individual designs of one thousand persons. Besides, the metal body is driving out the wooden body, and the latter before the standard automobile body will retain supreme. In this country the use of metal bodies is increasing tremendously and the greater ease of manufacture cheapness and practical indestructibility make them favored by manufacturers demanding large quantities of bodies.

Many of the automobile manufacturers make their own bodies, in this country at least, and there is naturally an increasing tendency on their part to specification of a few popular designs instead of pleasing the customer's individual tastes. It is still the custom in most cases to sell the chassis alone and have the customer order his own body attached. A much greater diversity among European cars is the result, and while this may appeal to some people it is decidedly uncommensurate. At any rate one must admit that a manufacturer who makes it his business to design automobile bodies knows better what would suit a customer than the latter himself.

The trend of the trade if examined carefully, shows the preponderance of four types of cars, and by gradual elimination of the various freaks and odd forms produced annually three four types will be generally accepted as standard for all cars and by all manufacturers. They are: The enclosed coupe for two and three people, the limousine for four people, the open-about or roadster for two people and, finally, the open touring car for five to seven people. These four types cover the whole field and until the actual arrival of the car of the future will be found sufficient to meet all requirements.

### Aeronautics and Aviation in 1912

THE year 1912 has witnessed greater development in aeronautics and aviation than any other year since the heavier than air machine was first conceived. Both air forces have been put to active military use by most of the large nations, and several nations have used dirigibles and airplanes to good effect in real warfare. At the end of 1911 it is possible that we shall have to record battles in the air just as last year there were several collisions in the air which were fatal. At present plans for airplanes to use in attacking other airplanes are an established fact, one of the best of these being the invention of Lieut. Cleland Davis, U. S. A., while Lieut. Wiley W. Post has perfected a bomb-dropping apparatus that leaves little to be desired, and has won it at the Michelin prize of \$10,000. He stands ready to deliver his device to any War Department that wants it and to instruct military airplanes in its use. Lieut. Post made a total of 47 of 15 hrs in dropping his bombs from a height of 2,900 feet upon a 12.5 ft target.

The principal lines of airplane development last year were two military and hydro-aeroplanes. England held a contest for military aeroplanes last fall in the United States in 1911, while all the leading nations used airplanes in the annual maneuvers. At

the close of the French maneuvers no less than 73 aeroplanes were reviewed by the Minister of War, and French pilots thought nothing of flying 300 miles a day during the war game. Flights totaling 40,000 miles were made in about a week's time. The first airplane in Connecticut and on the Pacific coast, Wright and Curtiss army airplanes were used. It was found possible to report to headquarters by wireless from a distance of 30 miles just what was occurring at the front. The chief difficulty experienced was the inability of the army two men—the first requisite of a military aeroplane.

After meeting with pronounced success the first of last year in the continuation of his hydro-aeroplane experiments at San Diego, Cal., Glenn Curtiss sent Hugh Robinson to the Monaco meet—the first hydro-aeroplane meet—in March. Robinson astonished the foreigners by his ability to navigate upon the open sea at Monaco. He had to compete only with a few other airplanes upon which floats had been hastily fitted. The result was that all foreign champions were eliminated, and in the fall a number of hydro meets were held. At the Aero Club House in the Grand Central Palace last May Grover Cleveland Looney, the author of "Monoplanes and Biplanes," exhibited the first "fly boat" consisting of an aeroplane, the body of which was watertight and formed a hull. He demonstrated successful flights with this new craft. Duane Lefevre, in France applied such a hull to a biplane in which André Beaumont flew from Paris to Boulogne over water.

Curtiss brought out a similar flying boat and our Navy has recently purchased one. The advantage of this type of hydro-aeroplane is that it can skim the surface of the water at 50 miles per hour and make 60 miles per hour a few feet above the surface with the least danger to the occupants. As a result four persons have made a trip of an hour or more in a French flying boat. There has been but a single fatal hydro-aeroplane accident, and that was due to foolhardiness, as mentioned in a recent issue. One of these machines flew double behind the flying boat, and while boasting with the dangers of the former entirely eliminated. Wheels may be fitted for land use as well, if desired.

Aeronautics in America received a severe setback early in July through the bursting of a valve in the "Akron" rigid dirigible. The dirigible was started in the morning of July 2nd, while maneuvering above the shallow water of the inlet at Atlantic City. Melvin and Calvin Vandeman and the three other men that formed the "Akron's" gallant crew felt their deaths when the dirigible, after its last flight, crashed into Atlantic with Wellman in the "America" had given his chief energy to the accomplishment of this feat. Finally, securing the financial backing required he had constructed the "Akron" for this purpose, but while building her he made an improvement which consisted of weaving wire in the cloth forming the gas bag so that the completed envelope was wire-reinforced like the barrel of a wirewound gun. The gas bag would then be strong enough to withstand the increase in pressure arising from heating and consequent expansion of gas. The envelope of the "Akron" Vandeman thought was strong enough to withstand a considerably increased pressure, and it is believed he allowed the pressure to increase when the sun came from behind a cloud, with the result that a weak section of the envelope gave way.

An equally appalling aviation accident that occurred on July 1st was the falling out of her 70 horse-power Hiotot monoplane of Miss Harriet Quibby and W. A. W. at the Boston meet. Miss Quibby, who was some distance behind Miss Quibby, was flipped from her seat probably as the result of suddenly developed gyroscopic force, and Miss Quibby immediately followed him. Both fell a thousand feet into shallow water, and were killed. Miss Quibby, shortly before, had won the honor of being the first woman to fly to this day to fly across the English Channel. She used a 50 horse-power Hiotot and made the flight from Dover to Calais in foggy weather. She landed at Harford 40 minutes after starting. Her accident at the Boston meet had no result for her two other flights, which have since been perfected, being obtainable at that time. One of these is a gyroscopic-controlled air automatic control for aeroplanes, which has been arranged to give automatic stability in all directions, and the other is a safety parachute for flying, weighing 6½ pounds, which is carried on an aviator's back like a knapsack and opens instantly when he is thrown out of his machine. Both are the inventions of Americans prominent in the electrical and aeronautic industries.

While there have been many long-distance airplane flights abroad, such as the 650-mile flight of Audemars in two days from Paris to Berlin, the only one of note in America was the 1,400-mile trip of Anthony Jannus from Omaha, Neb., to New Orleans in a Hiotot hydro-aeroplane. Jannus' flying time was 31 hours 43 min.

utes. He stopped at many towns on route, and gave exhibition flights. The 471 miles from Kansas City to St. Louis were covered by Jannus alone in 9 hours 38 minutes, which is about 50 miles an hour. Most of the express time was made. The 1,000 miles remaining were covered with a passenger and an 86-pound one of beer. The journey was made without any serious accident, the winding rivers being followed the entire distance. The replacements to plane and engine did not amount to \$25.

All speed records were broken in the Bennett Cup race at Chicago on September 9th, when Vedrine, on a 140 horse-power Duperdun "monocoque," covered the 124.8-mile course in 1 hour 10 minutes 37 seconds at the rate of 109.6 miles per hour. He covered 100 kilometers in 1 minute 27.5 seconds, or at a rate of 107.68 miles per hour. The American monoplane with 100 horse-power Gnome motor, built to defend the cup, was never flown.

As for the duration record, this was again raised by Pourcy on a Maurice Farman biplane from 11 hours 13 minutes and 30 seconds on September 11th. A distance of 626 miles was covered over a 10-mile circular course. In America Lieut. John H. Towers, on October 9th, made an endurance record of 6 hours and 10 minutes with his 75 horse-power Curtiss biplane monoplane, while on October 31st Walter E. Johnson, at Bath, N. Y., carried a passenger for 5 hours 51 minutes, with his Thomas biplane fitted with a 65 horse-power Kirkham Geylford motor. The greatest total distance covered over a circuit in a few hours was 1,000 miles between Valenciennes and Biarritz, traversed by Pierre Ducas in his 50 horse-power Borel monoplane also on October 9th.

Three notable altitude flights were made the latter part of the year, two by German and one by Looney. The record was raised each time. Looney, on a 100 Garmen now holds it with 8,501 meters (10,022 feet), subject to revision. He made the record at Tunis and then to New York—100 miles overseas—and thence to Italy and Rome—a total distance of 700 miles. This was the longest daring over water flight since Lieut. Bague was lost.

The international balloon race started from Stuttgart, Germany, on October 27th. The race was won by France by M. Hémard and Himmelspacher in the balloon "Eclair." The landing was made near Moscow, and a new record of 10,000 meters was set. The balloon was second with 1,200 miles, and John Watts of St. Louis, third, with 1,300 miles.

The requirement of aeroplanes by our Navy will probably be rapid from now on, since Capt. Charles de Gaulle's "Chandler" monoplane, which was built to be able to successfully launch an aeroplane from the deck of a battleship. The Navy already has four hydro-aeroplanes, and one flying boat in addition to eight or ten biplanes possessed by the Army. Recent experiments with the Navy hydro have shown that submarines can be easily located when completely submerged even in rather muddy water. The wreck of the American warship "Philadelphia," which stranded off Tripoli in 1903, was recently discovered from an aeroplane.

Future biplanes purchased by the Government are all to have monoplane bodies of streamline form, bodies similar in many respects to that of the Hiotot biplane used by Jannus. The two motored and duplicate twin propellered Wright biplane which the late Howard W. Gill was to use at the Boston meet, the Gould Scientific Aerocar, 18400 two motor plane, cost of \$10,000, and, last, also had a body with aviator's seat therein. The above event was declared off as Mr. Gill was the only entrant ready to appear at the stated time and place. In England lately successful flights have been made with a two-motored monoplane, the "Globe" built by Capt. de la Roche in 30 hours last summer with a machine fitted with four motors of 200 horse-power each. The first promulgated by Mr. Edwin Gould has, therefore, fruited.

### Shedding the Motor Car

WITH a view of cutting them out for mobilization, the French as well as the German government allows annual subsidies to owners of power wagons, motor trucks, and other vehicles. The subsidies are to the War Department specifications. The leading constructors are now building their wagon trucks with this end in view, and this leads to a standardization of the chassis as regards certain general ideas and other features, not including, however, with light rigid construction. The rules call for a 4-cyl. motor, 1000 cc. in capacity, and the preferred type carries about 8 tons load. Strict rules provide that the French cars shall be built entirely in France. The 5-ton car receives a first prize subsidy of \$200, a purchase subsidy of \$800 and an upkeep subsidy of \$200 during 2 years. The 8-ton car may the 5-ton wagon has subsidies of \$1,000 and \$500, respectively, for the same uses. Great Britain is now entering the movement, but the subsidies, \$40 to \$80, and 57% annual are much smaller. Austria has a similar system.

### Wanted: A Small Gasoline Plyow

To the Editor of the SCIENTIFIC AMERICAN

The above heading belongs mainly to me. Mr. K. M. Minkler, and named from the standpoint of the owner and operator of a gasoline outfit of this sort in the December 7th issue of the SCIENTIFIC AMERICAN, I have a few suggestions to offer (being a student of mechanics in general) that might be useful.

Now, to get at the root of the thing. A small gasoline plyow to be economical should essentially be light in weight and of corresponding small horse-power, so that fuel would not be too costly. But it must have as great tractive power as possible. Therefore, I believe that the novel traction wheel and tractor described in the SCIENTIFIC AMERICAN of September 7th, 1912, comes nearest solving the problem. It comes under the heading "Novel Italian Traction System."

ALVIN A. ANDERSON

Porterville, Cal.

### The Gyroscopic Effect of Motors

To the Editor of the SCIENTIFIC AMERICAN

In this discussion as to the gyroscopic action of rotary motors, and especially as to aviation, in the matter, the writer has come across the following footnote bearing on the question in a pamphlet entitled "Canter Lectures on Aerostation," by Charles Cyril Turner, being some lectures delivered before the Royal Society of Arts in 1910.

"It appeared subsequently, however, that with this rotating motor working at greater speed, it has a gyroscopic effect, and Delagrange, shortly before his fatal accident, told his friend, M. Cheneviere, that it kept the machine so rigid that he found it almost impossible to alter his course by moving the elevating plane, and that in order to descend he had to slow the engine slightly C. C. T."

It would appear that any danger due to the gyroscopic action of rotary motors—and also propellers—would exist only with very sudden changes of direction, such as might be caused moments by a sudden upward or downward wind-puff striking only part of the screw, or different parts at different moments, and that the aviator would rarely if ever change the direction of movement suddenly enough to bring this gyroscopic force into dangerous play, for it is well known that gyroscopic forces increase with the square of the speed with which the plane of rotation is changed.

It would also appear that gyroscopic force could be put to good use in steadying or even balancing a flying machine by producing a balanced effect with two or three sets of revolving motors—or motors and propellers—situated in both horizontal and vertical planes, each set consisting of two revolving in opposite directions, while one set of vertically revolving motors might extend fore and aft and the other transversely of the machine. It would be interesting, at least, to see these things tried.

ELMER G. SMITH

### The Gyroscopic Action of Gnome Engines

To the Editor of the SCIENTIFIC AMERICAN

I should like to make a few remarks on Mr. Earle L. Ovington's letter published in your issue of December 7th on the death of Paul Fick and gyroscopic force in an aeroplane using an engine of the rotary type.

In his letter Mr. Ovington asks if anyone has ever heard of an aviator who has really been killed by the gyroscopic motion of a rotary motor. I have never heard of a rotary motor complaint about its gyroscopic action. Of course Mr. Fick is dead and it would be a very easy matter for anyone so desiring to credit statements to him which he might make or not make. Mr. Ovington makes the statement that it was a fact that Mr. Fick was never aware of any gyroscopic action. According to him, therefore, it must be so, but it might be a good idea to hear from another aviator on the same subject. A few days before Mr. Fick was killed Mr. John D. Cooper, licensed pilot No. 60, questioned him in regard to his motor, and especially in regard to any gyroscopic action that it might develop. Mr. Cooper had never flown with a rotary motor, but was considering the buying of one. Naturally, in the course of the hearing all about them from an aviator who had had considerable experience with one.

Mr. Fick told Mr. Cooper that in making a turn he did the gyroscopic action of the motor, and accordingly if he was making a spiral. He said that in making the first turn he only felt the action slightly, but that in the second turn it was very strong, and that he seldom dared complete the third circle of the spiral. It was undoubtedly in making some turns that he was killed, and he therefore advised him to make, owing to the gyroscopic action, that he lost control of his machine and the sad accident occurred which resulted in his death. For we all know that it was in making a spiral that he met his

death, and that the machine never seemed to come out of its steep bank the least bit during its descent, even though Mr. Fick could be seen using his big hands, trying to bring it back to a level position. There can be little doubt about the gyroscopic action, about which he had spoken only a few days previous, having been too much for the contents of the machine once its full force was felt. I have every reason to believe Mr. Cooper's statement in regard to his interview with Mr. Fick.

I cannot blame Mr. Ovington for being so loyal to the type of motor that he has used most, for it is a poor kind of a sportsman who will not stand up for his favorite motor, and especially so when he has to use it as much for him as he, for we all know that he flew more miles in 1911 in a rotary-motored monoplane than any other pilot in the United States. I can only admire him for defending it so strongly, for its merits have been shown time and time again, but I fear that his arguments of late have been bordering very closely to narrowness, and to give the impression that he is far from being open to conviction.

While I do not hold a great deal of experience in flying with a rotary motor, I have made a number of flights in the most successful type of American-manufactured biplane, which happened to be equipped with one. I can truthfully state that I felt the gyroscopic action whenever I made a turn with it much more than I have ever felt it when using the stationary type of motor. And I can vouch for it that every student whom I instructed on that machine last winter in California will say the same. Therefore, I am not foolish in saying that the danger of knocking the rotary motor, for the wonderful records which have been made with it stand out as a glorious monument to its design. I simply state that there is a gyroscopic action when it is used, and this is far from being a point in its pedigree.

### Control of the Mississippi

To the Editor of the SCIENTIFIC AMERICAN

In the December 7th number of the SCIENTIFIC AMERICAN was published a letter by Mr. John Noble concerning the control of the flow of the Mississippi River. Mr. Noble suggests as a remedy "the construction of reservoirs in the upper courses and tributaries, in the case of the Mississippi the numerous tributaries of the Missouri in particular."

Possibly in the case of the Missouri Mr. Noble's plan may be of some merit, but the contrary must certainly appear to be the case with the Mississippi itself. Close to the head waters of the Mississippi in northern Minnesota at Wadena, Bemidji and Park Rapids, where the United States War Department has already constructed three large concrete dams, forming reservoirs many square miles in extent in the lakes and swamps through which the river passes. These dams have been completed and in operation for several years, quite a sufficient time to demonstrate their value in the control of floods, but the results obtained in that direction are very doubtful, so doubtful in fact that there has been serious complaint from people living on the lower lands along the river for at least three hundred miles below the dams, that their presence increases rather than decreases floods.

One reason that a system of reservoirs does not control floods is that the stream that breaks the dam's back, the extra water that causes the flood, comes on top of reservoirs already filled by a long wet season or by the annual spring freshet. It is not the unusual annual freshet that causes floods, but any unusual fall coming on top of this.

This has been shown by the reports of experts who have investigated the influence of a forest-covered watershed on stream flow as compared with a non-forested one. The forest floor acts as an enormous sponge, absorbing and retarding for a considerable period large amounts of water, and thereby regulating stream flow and lowering the volume of many small freshets. The authorities usually agree, however, that the ultimate high-water mark through which the stream is not lowered by the forest is the forest, for the known water that causes the serious flood always comes on top of a forest floor already saturated, a reservoir already filled; the result is quite as much run off as though the forest floor or the reservoir did not exist.

Mr. Noble suggests that by reference to our geographical maps we may learn that "certain characteristics and facts pertain to all of that large class of rivers which flow from the north to the south, that these rivers have their rise in hilly or mountainous countries." If he will turn to any good contour map of Minnesota, or of the United States, he may be surprised to learn that the Mississippi does not rise in a mountainous or hilly country, but that it rises in a level and down for the greater part of very slight relief and with an absolute elevation of only about 1,000 feet above sea level. The result is that the reservoirs overflow several thousand acres of low-lying land, which they convert into festering moun-

breeding swamps in summer and impassable tangle of prostrate water-killed timber in winter. The lakes converted into swamps, instead of being a source of beauty and a joy for fishing, as nature made them, have their natural shore lines spoiled and in many places made inaccessible and their waters polluted with green algae and pond scum as a result of the widely shifting level and the thousands of acres of water-clogged and now exposed swamps, which is caused by manipulating the gates of the dams to control the flow of water.

Perhaps the Mississippi can be controlled by a system of dams, but results so far obtained in Minnesota seem decidedly to point to the contrary. H. K. PLATT, Osakis, Minn.

### The Inventor and His Reward

To the Editor of the SCIENTIFIC AMERICAN

As an inventor I am gratified at the firm stand you have taken for the protection of the inventor's rights in the discussion of the patent bill now before Congress and you certainly have justice on your side. Article Section 8, of the Constitution says (par. 8): "The Congress shall have power to promote the progress of science and the useful arts by securing for limited times to authors and inventors the exclusive right to their respective writings and discoveries."

The word "exclusive" would seem to be broad enough to cover every point at issue, and would certainly cover the fixing of price and sales conditions by the inventor. Therefore, the Government has no right to interfere in the Constitution in Congress given power to abridge this grant other than by limiting the time it may run, and I am satisfied that the Supreme Court will take this view of the matter, in case the proposed bill should be passed.

The wisdom of the framers of the Constitution in recognizing the rights of authors and inventors is amply proved by the history of industry in this country.

The present stuporous wealth and prosperity of this country is due solely to its inventors. This seems a strong statement to make, but it is easy to prove its truth.

The vast resources have created since prehistoric times, but their present utilization has been possible only through the work of the inventor. The cotton gin, the steam engine, the steamboat, the steamship and the railroad made it possible to raise it in the interior, and it has gone on increasing until the year 1900 showed almost \$100,000,000,000 of cotton. This railroad, which first started in England, was first proposed by an American inventor and first brought to perfection here as a freight carrier. The steamboat was distinctly American. Agricultural machinery was the product of this country and without it the most fertile soil in the world would be a waste. Deere's "A" as it was once called. Here intensive farming will not pay on account of scanty rainfall but on extensive farming will, and on man can with the present labor-saving machinery farm as much as twenty men could by hand and do it better. The secretary of Agriculture estimates this year's farm products at nearly ten billion dollars. How much would it have been without the American inventor? What per cent of this enormous sum goes to him for his inventions?

John Deere, who invented the modern plow, McCormick with the reaper. Appleby with his twin harrow, are dead; their profits have long since vanished, but the country is still reaping the benefits. Was the exclusive right to inventors an injury? Goodbye struggled for years, in poverty and failure with splendid courage and hope, to make a useful product from the useless raw rubber. His ultimate success and the right for seven years to control his invention was a small reward for his long struggle. The Government not only gave him back his time it could not return his youth, all it could do was to secure his rights for a few years. Was this an injustice to the public? (Of what account was his profit in the first years of the industry created by his own efforts and his perseverance to which his own nation gave birth? And his story is but one. There are many others most of them obscure, who labored no less diligently to improve conditions and appliances of mankind, many like him unfortunates for their poverty and little fortune made still more bitter by the jeers of those who were striving to benefit.

It is any more than simple justice that they should be enabled to reap a monetary reward for the fruits of their labor? As you say, they have created some thing which did not previously exist and which would not have existed but for their efforts, and in which their right supersedes that of the public. On the other hand the first years of the life of an inventor may be very profitable, and the inventor frequently destroys what profit there is. The case of the Wright brothers is pertinent. They risked their lives in making flying a success and have been engaged in expensive litigation since the issue of their patents, to secure the rights and profits which were rightfully theirs.

Instead of detracting from the value and profits of an inventor it would seem more worthy for a Congress to secure the inventor more fully in his constitutional rights. Omaha, Neb. W. NARRIS

The spreader room of a rubber factory

## The Making of a Pneumatic Automobile Tire

### A Trip Through a Tire Factory

By E. R. Hall

**C**URIOUSLY rubber never reaches the manufacturer's hands. Before it can be converted into a tire it must be washed first. It is cut up into small pieces put into large vats of warm water and allowed to soak in order to soften it sufficiently to be broken down in the mangle. By means of a cracker machine consisting of two rolls with projections on their surfaces shaped like little pyramids, the two rolls revolving with a differential one going considerably faster than the other and being adjustable so that they can work close together or with some distance between them, the rubber is broken down into a coarse, spongy mass. Water flows on to the rubber during the process bringing down sand, dirt, bark and the many other foreign materials which come mixed with the rubber. The rubber is put through this machine a number of times until it is worked into a uniform condition. Some of the rubbers like the *Ceylon* and *Para* will sheet out into a coarse sheet by being put through this machine, others like the majority of the *African* rubbers will fall apart and come down in chunks and have to be fed into the machine with a shovel.

After the rubber is broken down sufficiently in the cracker it is next put through a washing machine built like a cracker except that the rolls are grooved or rifled so that their action is not so severe. Water constantly runs over this machine and the rolls work very close together so that the rubber is finely ground and run out into a thin and comparatively smooth sheet allowing the water flowing between the rolls to take out practically all of the foreign matter that remains. Some types of rubber such as *Manila*, which have large quantities of sand in them are washed in a special form of washing machine known as the *beater washer*—in endless, oval shaped trough with a fast revolving paddle wheel in this machine the rubber is submerged in water after being broken down in the cracker and the sand is literally knocked out of it by the paddle wheel. The sand

Mounting the partially cured tire on a rim preparatory to final vulcanization in inflated form

Machine for cutting the fabric into thin strips.

drops to the bottom of the machine where it is drained off, while the rubber floats to the top to be gathered and then put through a regular washing machine for the final sheeting out.

#### How the Rubber is Dried.

Before the rubber can be used in any articles of commercial value it must be thoroughly dried. Any moisture in the stock would turn to steam during the vulcanizing process and give rise to blisters or blow holes in the goods. There are two ways in which rubber is usually dried. The method mostly used and generally practiced with all the better grades of gums, is to hang the washed strips on horizontal poles and space them in slides, so that air may freely circulate around the surface of the rubber, the dry room being kept at a constant temperature. To dry the rubbers properly by this method takes from four to six weeks.

The other method is vacuum drying. Low grade rubbers which have a comparatively large percentage of resin in their composition cannot bear their own weight when hung on horizontal poles but drop off. Hence these rubbers have to be dried in a peculiar manner. They are laid in trays which are placed into a large air tight receptacle. Then the air is withdrawn and the interior heated by means of steam coils. Thus the water is evaporated from the rubber at a considerably lower temperature than that at which water boils under atmospheric pressure, and at such a low temperature, and in such a short time, that the rubber is not affected. By this process, these rubbers can be dried in a few hours.

#### Ingredients and Their Purposes.

After having been thoroughly dried, the rubber is ready to be mixed in proper proportions with the various ingredients, which give the desired quality for various products. In order that rubber shall vulcanize, it is necessary to mix with it a certain proportion of sulphur, vulcanizing, or curing as it is sometimes called, being merely the causing of a physical mixture of rubber and sulphur into a chemical

Applying the tread.

Arranging fabric on tire-building machine

The wrapping room of a pneumatic tire plant

compound of these ingredients, by the application of heat. Besides sulphur some of the more important ingredients used in compounding rubber are:

**Flax Oxide.** This toughens the rubber and increases its wearing properties and tensile strength.

**Barium Sulphate.** This stiffens the rubber and adds weight, so reducing the cost.

**Lithopone.** This whitens the stock and makes it soft and is used extensively in druggists' sundries.

**Antimony sulphide.** This makes the stock red and is a preservative against oxidation.

**Zinc oxide.** This has the same action as antimony sulphide but makes the stock black.

**White Lead.** This hastens the cure and is extensively used in gray and black stocks and is a good filler or weight additive.

**Magnesia Oxide and Carbonate.** These are used as fillers for white stocks.

**Oxide of Iron.** Used for coloring red and yellow stocks.

**Slime (unskated).** This hastens vulcanization and chemically removes any water left in the rubber.

**Whiting.** This is used only as a cheap filler to increase quantity and lower cost.

**Aluminium Silicate.** This is used chiefly as a filler.

The various ingredients mixed with rubber are not put into the compounds merely to cheapen the product and to lower the grade of the material. White traw of molded goods, rubber heels, bicycle grips, automobile bumpers (etc.) is not free of tires, lacking belting etc. In greases are added in the case of tires

Finishing pneumatic automobile tires

Room where the compounded rubber is put through calenders.

to toughen the gum, increase its wearing qualities to make it indestructible when subjected to heat or to make it soft and yielding so that it can be forced into fabric, etc.

In the actual process of manufacture, the sheeted rubber is sent directly from the dry room to the compound room where the various ingredients are weighed out into proper proportions along with the rubber to make up a batch and placed in receptacles ready to be mixed. The batch is then sent into the mill room to be mixed into a uniform pasty mass, which is the characteristic unvulcanized or scoured green rubber compound. The mixing is done in the mill, a very heavy machine, resembling a mangle and a washer, except that it is much larger and heavier and that the rolls are perfectly smooth and run close together. No water at all is used on the batch during the mixing.

After the batch is properly mixed it is cut off the rolls in sheets and rolled up and sent to the green stock storeroom. In this storeroom the compounded unvulcanized gums are kept in different bins according to the nature of the compound and are there allowed to season a certain length of time after which they are delivered to the various departments of the factory in which they are to be used.

Another form in which rubber is used is the scoured rubber cement. Rubber or any of its compounds are readily soluble in naphtha. In this process the compounds after being milled are pulverized in specially constructed cement mills and then mixed with a certain proportion of naphtha which gives a thick solution

(Continued on page 16)

## Europe's Good Roads

What They Mean to Road Users

By Francis Miltoun

*This article is a review of the best road engineering practice of Europe. While there are just as good roads in the United States today as in France, for example, our mileage of good roads is hopelessly outdistanced by the corresponding mileage of European countries that cannot compare with us in population or in national wealth. As a matter of business itself, the good roads question is one of the biggest on the economic horizon to-day. Americans should know how Europe is endeavoring to solve that problem. This article will tell them.—Barron.*

It is no retrograde movement that procures comfortable travel by road as one of these twentieth century blessings which is our due. It is an axiom that the speedy railway development of the United States worked to the detriment and discouragement of scientific road building. Old baroque suffered under no such handicap. Roads, more or less accessible were there. Take the case of France as the reactive, concrete example, because France has the greatest continuity and excellence of good roads today—since the Roman invasion, a fact which is attested by one of the estimated *bornes milliaires*—the mile stones of the Roman era—which still beside a tree-bordered Route Nationale, not a stone's throw from where these lines are written. The roads of that were planned on grand lines, their great scope even at this late day cannot be denied and proves that they are a tangible expression of planning for the future. French roads of today follow these same general lines. It is true that Europe got her start. What is more remarkable France, through the application of the same nation wide governmental and centralized road control system, has reduced the time (in some things less than three quarters of a century) with highways as good as those of the mainland itself. It is not solely this because a country is so that its roads should have been ignored or neglected not even on the industries of big business for as a matter of business itself the good roads question is one of the biggest on the economic horizon today.

### The Influence of the Romans.

All this has for long been recognized in France and her famous Ecole des Ponts et Chaussées (which gave the inspiration for the establishing of the highway engineering elite at Columbia University) turns out its road engineers all trained to the same methods. This of itself produces a uniformity of design and treatment which has done much toward putting French roads into the enviable class in which they stand. If a further endorsement of this materialism were needed it can only be added that the recently founded department of the government (the *Office National des Pontons*) is working hand in hand with the road building authorities for the provision of the funds necessary to build new roads which shall open up many hitherto closed regions to a rapidly increasing tourist traffic. This is not in any means an idle entering to the class of labor, the spenders, the development of a hitherto inaccessible region to tourists means that all the allied industries which have previously have been pushed will at last become producers able to furnish a more comfortable livelihood for many a mountain community which hitherto eked out but a pitiful existence or emigrated to the shores of the Seven Seas. It was this combined effort of two friendly governmental departments which brought into being the magnificent *Route des Alpes* from Lake Lemano to the Mediterranean—five hundred miles of superb mountain roadway through the Alps of Savoy and Dauphiny and which in a like manner is rebuilding the *Route des Pyrénées* from the Bay

On a Swiss mountain road.

An Italian highroad through a hill town in Tuscany

The French have built fine roads in Algeria. This is the Col de Sfe, the gateway of the Garden of Allah (Mekra).

Broad flat flagstones mark the through routes passing through Italian towns.

of Biscay to the Mediterranean. The famous *Carriac d'Or* of the Esterel, too, a magnificent forty kilometer stretch of shell like, cliffside Mediterranean, bordering the Riviera, just before Cannes, owes its existence to a like initiative. Formerly it was but a coast guard's trail, today it is the most beautifully disposed and most remarkably engineered roadway extant.

It is remarkable the wide interest that the road question has for all classes in Europe and it is this unity of purpose that builds on the net work legacy left by the Romans. Since that time, and that of the Huns and the Lombards, to whom were due much of the elements of levity that compose the French road system to day particularly with respect to free planning alongside, and since the later day of the military road making genius of Napoleon much has been undertaken in the way of refinement which has produced, if not an actual money return, at least a prosperity which would otherwise have been unknown.

### European and American Roads Compared.

To be just there are as good roads in the United States to-day as in France. In top-dressing, in comfort with the needs of the new locomotion, according to any one of the four or five methods commonly made use of in America results are superior even to anything yet achieved in Europe. That these "surface roads" are as durable is a question not for discussion here. The rock metalled, water bound macadam of Britain, precursor of the Frenchman, Trevaquet, the engineer of Germany or the poet of Belgium at their best are certainly no better to the eye, nor in actual practice when seated on luxurious upholstery and rolling on rubber tires, than much that may be seen in short lengths in some States of the Union.

Little has been achieved in Europe in the redressing of existing roadways (with asphalt, cement or any form of bitu- licious carpeting which is known so favorably, in one form or another, in America, and which in most cases has been found superior to purely water-bound road-surfacing). In France, particularly, where the thing has been tried, pitiful results have accrued, notably on certain stretches along the Riviera, that battery of Mediterranean coast towns which has become the playground of princes, American millionaires and some others.

Brick is found on some roads of Holland, but it dates from before the automobile era, before even that famous peninsula of Terre Haute, Indiana, owing already to some twenty years and still good. Great claims of durability are made for brick, and if these two examples have any weight, the thing would seem to be worth something.

In France there is a famous forty kilometer stretch of *Route Nationale* in the south, near Marseilles, just after leaving Avignon and Arles on the road to the Riviera, straight as an arrow, flat as a billiard table and smooth as marble, with a road of wind-break cypress on the right, which in the writer's opinion is the very finest ideal roadway. French

National, Departmental and Communal roads, as a class, are the best in the world. Here and there, it is true, they are showing signs of wear, but the system of upkeep is such that they seldom degenerate into downright bad. From the Channel Ports to Paris there are superb bits of tree-lined roadway, wide well drained and macadamized surfaces, the typical *Roads Nationales*, which have set the pace for all other main highways of the world. South in Poitou and through the Limousin are long silent stretches nearly as good. In the Pyrenees are found superb mountain highways. In the French Alps and some of the most beautiful, unspoiled on the Spanish variant, with the result that Alphonse XIII, Europe's automobile monarch, does most of his road travel in France. In the French Alps are the finest mountain roads in Europe, far and away ahead of those of Switzerland on all counts. Many of them were due to the genius of Napoleon and his military road builders, and if their main purpose in those past was strategic, to-day they are certainly essentially practical. The Col du Mont Cenis, the Col de Mont Genèvre, the Lauter and the giant Gallier (the highest carriage road in Europe save the Stelvio) at an elevation of a mile and two thirds, are the best of their kind, though commonly one thinks of the mountain republic of Switzerland as Italy or Austria when mountain roads are mentioned.

#### The Mountain Roads of Austria.

The mountain roads of Austria are a close second, particularly when it comes to considering them from the point of view of the automobile. The country is trying hard to get some of the thirty million which is claimed to be left abroad each year by foreign automobilists in Europe, and it has accordingly put its mountain roads in shape and opened up many new ones within the last decade, until to-day there is a continuous road of fifteen hundred miles at no less an elevation than three thousand feet, with many of the passes, like that of the Stelvio well above six thousand. Automobile Switzerland is a big loser with its circuit system of cantonal options, resulting in that it is but a bridge for the "fast traffic" between Paris and the Italian Lakes instead of being the touring ground that it is in the eyes of a former generation. One enters Italy over the Saint Gothard or the Simplon or Tyrol over Arlberg, but a bare three hundred miles of cross country is all that is left to Switzerland on the main touring route, the valleys and many of the interior roads being given over exclusively to carriage and mail coach, horse-drawn traffic of the days of Mark Twain.

Italy has a nationalized road system so has Belgium, Austria and most of the German Confederation. The first three meet the situation but partially, organization and control being decidedly inferior to that in France. Italy's *Via Nazionale*, *Grande Comunicazione* are sometimes good, more often bad, and around Naples, Rome and Florence and north toward the Italian Lakes lie Milan they are too bad for words, having arrived at this disgraceful full stage through sheer neglect or intention rather than through any fault in the system of road building in itself. Level crossings, with great well-kept gates, always shut, abound—there are fifty of them between Viminale and Spessa on the Italian Riviera, the Poor Man's Riviera, so-called to distinguish it from that around Nice and Monte Carlo.

To sum up and bring it home, there is nothing worse in Europe than stretches within half a hundred miles of Manhattan, and nothing quite so good, even in the *Belle de Belgique*, as some of the hard-surfaced ribbon roads leading out into the Jersey Hills. Roads in Europe are an economic factor of life and not a fad, however. Recently we read of an army division in the Balkans which made a hundred miles with all its military equipment in a little more than a week, and that truly is going some, even on a first class open road, and military strategic roads are in variously good roads, though they may not be so numerous or have the extent of those mountain thoroughfares which lead merely from town to town. Neither is the farmer abroad taxed in strength, patience, time or money. In France he is assured a road grade which

will enable his beast of burden to pull three tons at a walking pace without aid, an echo of a formula first promulgated by Napoleon—no grades upon which a mountain battery might not gallop at ten kilometers an hour. It is this general, forward-looking, later looking engineering scheme that puts the continental European roads from the Pyrenees to the Pyrenees in the high class which they occupy as strategic military roads unexcelled anywhere. Their "feeders" are of the same general excellence resulting in a benefit to all sorts and conditions of society not automobilists alone,

National road through the forest of Fontainebleau.

The Gorges d'Ollonville in the Maritime Alps.

though, to be fair. It was the advent of the rubber tire that has caused the wide revival in the question of road travel throughout the civilized world.

#### England's Parcelled System.

England's parcelled system of road control is the chief of the difficulties which road users are experiencing in the tight little isle, and have experienced for long, though it is hoped that the newly founded Road Board (whose secretary, Mr. Ross Jefferys, was recently in the United States to learn what he might with regard to the failing down of automobile roads, particu-

larly with respect to surfacing) will remedy all this just as soon as it becomes really national in its functions and not merely advisory, leaving the county and parish authorities to do pretty much as they please. Towns and villages in England are often so close together that a highway is frequently one long main street—across and winding at that, and the famous Bath Road of history, for a length not appreciably more than a hundred miles, is under control of a dozen different road builders, each with methods of his own. Results are variable. One length of but a few miles, entering London from the east, is under the régime of three different urban councilors of greater London. In France, or in any of the continental countries where the national system prevails, this cannot be.

Uniform control in France makes a national road of the main street of many a populous town and as such it is under the direct supervision of the national road building authorities and as goes without saying, is kept up to national standards often having a stone kilometer mark set into the facade of the town hall or a Gothic church which may date from the middle ages. It is as if the Alps Highway, or *Roads Nationales*, from which the French *Roads Nationales* of to-day has descended, were snubbing along in the open plain of La Beauce, the granary of France where for miles on end there are nothing but waving wheat fields on either side no hedgerows, as in England, no paving blocks as in Belgium and no make-shift fences as in America—nothing but straight white, smooth surfaced road way along which the automobilist may make what speed he may so long as he doesn't hit anything.

#### Speed Limits in European Roads.

Speed limits in continental Europe save for local option in the *apportionations* the populated centers are in general twenty liberal only in Britain and in Switzerland are they intolerable. If one exceeds the ludicrous frequency of the posting of the word *retards* in Germany particularly in the Rhine Provinces of the Confederation.

European roads by no means cost as much as in America wages are lower to begin with and the budget is spread thin. France a ideal centralized system costs but six francs a mile a year and the road classification of *Roads Nationales* little more than four thousand dollars a kilometer, with certain classes of local roads falling as low as four hundred. It is significant that road markings form as much a part of the European nationalized road system as roadmaking. Street head stone like kilometer stones stick out at every five eighth of a mile and white cast iron standards are at every cross-road. In America we have depended largely upon private initiative to give us road directions with it must be confessed unsatisfactory results, notwithstanding the first instance that this, the intent was good.

German and Austrian roads as a whole are excellent in their main lines of communication and the mountain roads of the latter (which also has a National Touring Office which is fathering a pet project to make for the Alps of Tyrol and the Bohemian Forest) which the automobile tourist finds to find in Switzerland ended after the French formula turn them a close second and are even more spectacular in that they frequently pass through long stretches of wildly scenic country less thickly populated than Dauphiny and Savoy in old France.

Certain German roads are under particularly stringent road regulations and level taxes for upkeep and these laws are on the stranger and the native alike peculiarly commendable. In the Black Forest and about the Rhine German roads reach this apex and are no way inferior to those of France which indeed so far as those of Alsace and Lorraine are concerned are allied to the French tradition of engineering if not of upkeep.

The frontier customs control stations of continental Europe play a well defined part in the policing of (Continued on page 10)

# Clever Devices that Help Motorists

## European Inventions That Meet Real Needs

It must be stated emphatically here that the technical refinements and auxiliaries to be described were not caused by any distrust in the ability of the cars to surmount the mountain difficulties, but by a desire to save time, trouble and possible penalties during the tour.

As usual in races and reliability trials, the lubricating apparatus received the most careful attention. Almost every entrant had a little trick of his own by means of which he could increase his available oil supply, or accelerate the flow of lubricant to the parts where it was needed. Brakes and gasoline tanks also received due attention, priming apparatus and a host of unique improvements were invented and attached by the drivers themselves.

An English car, for instance, had a special rear spring suspension, shown in Fig. 1. The lowest of the horizontal leaves is fully six feet long and rotates in the center on a fixed pivot, as well as being fastened to a hinged support on the chassis frame. This construction is productive of extremely easy riding owing to the great length of the spring.

In an Austrian car, shown in Fig. 2, the manner of attaching the two spare wheels is unusual. The chassis frame carries a right angled iron pipe, threaded at the free end, upon which the wheels are slipped and retained by the cap B and the nut S. The nut is fitted with a short handle, facilitating quick removal of the

wheels. The brake adjusting device, shown in the same illustration, is the same of simplicity. It consists of nothing but a double-threaded spindle inserted in the brake rod. To keep continuous watch over the motor a small electric lamp L is affixed to the dashboard directly behind the engine, the whole being visible through the glass window B in the dashboard.

An Italian car sported a queer looking radiator cap shaped like a rounded cone (Fig. 3), for the double purpose of condensing the steam rising from the radiator and preventing hot water from being carried away with the steam.

Three emergency tanks were carried by a French car, illustrated in Fig. 4. H represents the gasoline tank, W the extra water reservoir and O the emergency oil tank. The gasoline tank is of great capacity and is filled through the top of the back of front seat.

The most novel, interesting and important device, however, was seen on an Austrian car, shown in Figs. 6 and 7. While the arrangement of the emergency gasoline tank under the front seat is common practice, the installation of an air filter on the dashboard is a step that will be watched by every automobile manufacturer. Dirt and dust carried into the carburetor through the air ports, are responsible for a large part of all the carburetor troubles and any means tending to eliminate this difficulty must needs command attention. The filter is pictured in Fig. 6, where W stands

for the dashboard, B for the pipe leading to the carburetor, R for the permanent sieve and T for the easily removable linen filter, held in place by a brass ring. The chief value of the device lies in the accessibility of the filter, and its removable linen sieve, which when clogged up can be replaced by a new clean one in a moment without stopping the car or the motor.

One of the big German cars, outlined in Fig. 5, evidently took no chances in being caught without a sufficient supply of gasoline. The carburetor of this machine was of such a construction as to render the use of gasoline of different specific gravities unsatisfactory and in order to obviate this difficulty a plentiful supply of the sort of gasoline best suited to the carburetor was carried along sufficient for the entire trip. The net weight of this extra supply was more than 100 pounds. H and O are pressure tanks, which supply the carburetor by gravity feed.

Fig. 8 gives the arrangement of one of the many clever oil accelerators used on the tour. The pump P forces air into H, where it escapes through either A or B, according to the position of the two-way cocks. A leads to the oil tank H to the water reservoir. A leads to the oil tank, B to the water reservoir. The oil is not forced directly from the tank into the motor but rises first in the pipe R falling through a filter and the pipe O into the motor. In Fig. 8a is shown how the compressed air from the pump P, going through

(Continued on page 61)

'Unpardonable infractions of the rules and regulations' on to incline to call the little technical tricks and the refinements with which the participants in one of Europe's recent reliability races for automobiles equipped their cars. Although the aim of the tour was not to test and develop fresh accessories for use on motor cars, the tourists felt the need of a little assistance in crossing the Alps during a winter. Consequently they reached their brains for ways and means to increase the power, fuel economy and lubricating facilities without transgressing the letter of the contest rules. The following article, condensed from the *Alpine Auto mobil Zeitung*, succinctly describes the clever devices invented for the occasion—KRON.

Fig. 6 and 7—A clever oil accelerator. The pump P forces air into H, where it escapes through either A or B, according to the position of the two-way cocks. A leads to the oil tank H to the water reservoir. A leads to the oil tank, B to the water reservoir. The oil is not forced directly from the tank into the motor but rises first in the pipe R falling through a filter and the pipe O into the motor. Fig. 8a shows how the compressed air from the pump P, passing through the reducing valve V, to the fuel tank, forcing gasoline into the separator W where it is freed from water, and then through F to the carburetor.

Fig. 8—Another oil accelerator. The pump is here located between the two front seats with three pipes: A for suction from the oil tank, B for suction from the water reservoir, and C for connection with the motor. The air from the pump P, passing through the reducing valve V, to the fuel tank, forcing gasoline into the separator W where it is freed from water, and then through F to the carburetor.

the reducing valve *K* to the fuel tank, forces gasoline into the separator *W*, where it is freed from water, and then through *V* to the carburetor.

Somewhat similar is the construction shown in Fig. 9. The pump is here located between the two foot stems, with three pipes *B* for suction from the oil tank, *L* leads to the motor, and *L* to the tanks.

A priming device which was on nearly all the cars is shown in Fig. 10. It consists of nothing more than a wire protruding through the radiator and attached at the other end to an angular lever *K* is the carburetor, *H* the float stem, *H* the lever, and *D* the wire.

More ingenious is the device shown in Fig. 11, which one of the drivers employed to obtain quick adjustment of the fan belt drive, without being compelled to stop the car—the fan being a non-stop contact over mountain roads. *X* and *Z* are actuated by the rod *W*, *H* is firmly fastened to the sector *X* and carries the shaft of the rotating fan, *R* is the belt. The rod *W* is controlled by a lever on the dashboard.

Still another clever device was used by a German car, and is illustrated in Fig. 12. It consists of a wind shield having a narrow slit in the glass. The arrangement guarantees a clear view ahead even if heavy rain and mud cover the lens, while the sliding pane or pane or pane allows each driver to adjust the height of the slit to his own requirements, by means of the usual device, shown in Fig. 13.

The last two illustrations show a time-saving device, which is not unknown in this country, in connection with the older handling of touring maps. By means of rollers and a small frame with a glass front it is possible to keep the map in full view and yet safe from being blown out of one's hand, while the entire plate and holder can be folded under the cover, out of the way when not in use. Special ribbon like maps are used in this device.

### The Carob Bean Tree

THE carob bean is the commercial name for the ripe pods or fruits of a tree called botanically *Ceratonia siliqua* Linn. of the pea family of plants. The fruit of this tree is variously known as carob, carob bean, alga, algaroba, algaroba, carob, carob, locust, sweet bread, sugar pod, and St. John's bread. It is supposed that these seed pods are the same as the honey which St. John found in the wilderness, hence the derivation of the common name of St. John's bread. The "hunks" on which the prodigious son of scripture subsisted were the dry pods of the carob bean. The tree is a native of the Caucasus, African and Asiatic countries bordering on the Mediterranean Sea, but it has now become naturalized in practically all localities in which oranges are grown. It is a beautiful evergreen tree attaining a height of from 40 to 60 feet, and is now being cultivated very generally and plentifully in southern Europe both for shade and for the edible pods. The yield of these pods per tree is often great. Some trees frequently produce as much as 800 or 1000 pounds.

The carob tree does not stand frost but it grows well in dry rock soil and should prove a valuable acquisition for planting in parts of the southern States. The United States Department of Agriculture, has, from time to time, procured and distributed many hundreds of young carob trees, chiefly in Texas, Florida and in other southern States. In order to encourage its cultivation in Florida, the department procured it in the experiment garden at Miami, Florida. In response to numerous requests received from farmers and others, the station distributed seeds and cuttings, and a number of healthy young plants are now growing in the southern part of the State. This valuable tree has been tested also in southern California, and its culture doubtless, will become quite general, because there is no other tree that is likely to become more popular for shade and ornament in dry, rocky situations than the carob tree. It can not only be trusted into a very ornamental shade tree, but may be planted as a wind break to more tender vegetation. Its introduction into southern New Mexico and Arizona has been recommended as an important addition to the food supply for stock in these States. Occasional trees are now growing around San Antonio, Texas.

The carob tree is at present cultivated in all warm countries which suffer from periodical droughts, its long roots penetrating to a great depth in search for water. It will grow on almost any kind of soil, provided it is thoroughly drained. In southern Florida it grows very rapidly on the dry shallow soil underlaid with the porous coralline limestone. It is said to prefer limestone soil, but it will flourish on almost pure sand or on rich alluvial soil. The carob tree is very common in some parts of the Canary Islands, and in 1888 was introduced to Jamaica. Its introduction into the arid parts of Chile and Argentina has been attended with considerable success. It is grown also in Australia in South Africa, Australia, and French India. In all these countries the carob tree can be grown in places where no other tree will grow, notably on the dry arid regions, and it seems certain

FIG. 14a.—The map holder shown in Fig. 13 in place. The entire plate and holder can be folded under the cover out of the way when not in use.

that in the endless varieties of soil and climate found in southern New Mexico and Arizona there must be many districts where it would prove very successful. The introduction of this tree would be equally valuable to the people along the Rio Grande, especially at times when forage for their sheep is scarce. Not only does the carob tree furnish food for horses, but also shade for cattle and sheep.

In practically all tropical and subtropical countries the tree is cultivated and its pods are used to form an important article of trade. The fruit is a dark brown leathery pod of from 4 to 10 inches long and often an inch or more wide, but not over a quarter of an inch in thickness. It contains a gummy, pulpy substance of an agreeable sweet taste, which renders the pods an important article of food for the poorer classes wherever the tree grows. Although the edible portion of these pods contains about 80 per cent of sugar, it possesses very little real nutritive value, the mechanized matter belonging to the class of foods called carbonaceous, the seeds alone possess nutritious matter, and these are flat, hard, shining-brown, about the size of a lentil and cannot always be readily masticated. In recent years these pods have been imported into England and exported to England as food, a common article of sale in the small shops of the poorer neighborhoods of London and New York, where the children purchase them for the sake of the sweet pulp which surrounds the seeds. Large quantities of these pods have been imported into England as food for horses, and it forms one of the chief ingredients in the patent cattle food. The value of the carob beans exported from Cyprus, an island in the Mediterranean Sea, has in some years reached over \$500,000. Not only are the pods valuable, but every part of the tree is useful. The wood is hard, heavy and is very durable in contact with earth and water.

The carob tree is propagated usually by seed, which is the most natural and also the easiest method. Propagation by layers, cuttings or grafting may be advisable if one wishes to be sure to grow a special variety, of which there are a number, but to make a start in carob culture it will be best to plant the seed, and other methods can be attempted later. The best time to plant the seed is in August. The covering of the seed is very hard, and in order to hasten germination it is recommended to place them in hot water (not boiling) until they are softened, which may take from 2 to 10 days. When this is done the seeds should be planted at once in their permanent places. In this event, the young plants must be watered regularly and kept free from weeds until they are old enough to take care of themselves. When cuttings are used these should be prepared about 6 inches long from matured one-year-old wood in March or April. The advantage of propagating the carob tree by cuttings is that fruit bearing trees can be selected and in this way regulate the number of male and female trees. To insure the fertilization of the female flowers there should be from one to two males to every 10 female trees. Those who cultivate the carob tree in the Orient usually keep bees, because it is by means of these insects that a great many flowers are fertilized.

The distance the trees should be planted apart depends upon the local conditions, and the object of the plantation. If it is planted for a wind break, 8 feet apart will probably not be too close. In cases where it is desired to grow large trees for the fruit they produce, 30 feet each way is recommended.

### Motor Trucks Articles in Next Week's Scientific American

THE subject of the automobile is now so big that it is impossible even in an enlarged issue of the *SCIENTIFIC AMERICAN* to discuss all its phases. In this number we have contented ourselves entirely to describe cars. Since the motor truck cannot be ignored, we will devote to it considerable space in next week's *SCIENTIFIC AMERICAN*. In that issue the reader will find a general article in which the capabilities of motor trucks are generally compared with the capabilities of horse drawn vehicles in one of those comparative drawings which were invented by the *SCIENTIFIC AMERICAN* many years ago, and which tell their story more tellingly than words. There will also be a table of motor trucks similar to that of the table with electric pleasure cars to be found this issue on page 44 and 46, but in that table motor trucks will be classified, not according to price, but according to their capacity.

### Preventing Oil Cloth from Cracking

A GOOD way to prevent oil cloth from cracking when used as covers for tables is as follows. A few thicknesses of paper are placed on the table and matted together with oleic acid. This will cause the oil cloth to set, much longer, and prevent cracking of the paper. The paper should be stretched tightly over the table.

# No-Rim-Cut Tires 10% Oversize By Far Outsell All Others

## This Winter Tread Will Indicate Why the Goodyear Won

Last year we sold 918,687 automobile tires.

Yet we failed to keep up with the flood-like demand by some 400,000 tires.

Seven years ago only one tire in ninety was a Goodyear tire.

Three years ago the demand was still one-twelfth as large as now.

Last year's sales by far exceeded our previous 12 years put together.

### Note the Double Thickness

In this Non-Skid tire we add an extra tread almost as thick as the regular. Thus we give you a double-thick tread.

This extra tread is of very tough rubber, immensely enduring, almost impervious to wear.

Because of its thickness, the blocks are deep cut. Their non-skid efficiency lasts for thousands of miles.

### A Bulldog Grip

These sharp-cut blocks present to the road surface countless edges and angles.

They grasp the road in every direction with a fairly irresistible grip.

But the greatest advantage lies in the fact that these blocks widen out, so they meet at the base.

They are not separate projections, which center the strain on a small part of the fabric. They distribute the strain exactly the same as with smooth-tread tires. That's the main reason why the Goodyear Non-Skid gives such exceptional mileage.

Compare this tread with others.

Compare its thickness, the depth of its projections. Compare the apparent efficiency, due to these sharp-cut blocks.

Compare the way in which strains are distributed as the fabric can't be broken. One glance will show you that this Non-Skid surpasses anything else of its kind. About 250,000 of these treads have already been tested out.

### Other Troubles Ended

Thus we have ended skidding troubles in the most effective way.

Years ago we ended rim-cutting, just as completely, just as efficiently.

Our patent tire—the No-Rim-Cut tire—has made rim cutting simply impossible.

What has awakened men to Goodyear tires in this overwhelming way?

This winter tread will tell you. It shows how far we go, in every way, to multiply efficiency. To cut down tire expense.

This is only one item, but it reveals the entire Goodyear code.

Compare this tread with others, and you'll see why Goodyears won.

And that alone cut tire expense 25 per cent.

Our 10 per cent oversize, under average conditions, adds 25 per cent to the tire mileage.

Our fourteen years of ceaseless tests and comparisons have brought our tire quality up to the maximum.

These things together, in the test of time, have placed the Goodyears on at least a quarter million cars.

### One Must Respect This Verdict

Remember, please, that tire expense forms your major cost of upkeep.

A tire which cuts that cost in two is something quite important.

Men know when they get it in these

days of odometers. They know which tire serves best. And the final verdict of these men who know favors Goodyear tires.

Men have tried and compared now pretty close to 2,000,000 Goodyear tires. As a result the sale of these tires has doubled every year. And last year's increase was 125 per cent.

Now these tires by far outsell all others. And this year's output, if this increase continues, will completely equip 500,000 cars.

One may easily question any maker's claims. But when hundreds of thousands of users unite, one must respect their verdict.

The verdict of experience favors Goodyear tires in an overwhelming way. And every month makes the verdict more convincing.

Is it not fair to suppose that your experience will bring a like result?

If you think so, get that experience. Make some comparisons. Settle this question by next time insuring on Goodyear Non-Rim-Cut tires.

Write for the Goodyear Tire Book—16th-year edition. It tells all that we know, after fourteen years, about cutting down tire expense.

## Choose Your Car Now

**N**OW is the time to decide what car you are going to buy. The automobile shows bring all of the cars before you. You have a chance to study them—to compare them point by point.

We do not expect you to buy a Chalmers car simply on our word that it is the best value at the money. Although many people do accept our word in the matter and we know it is good. But you will want to see all of the cars and to compare them as to quality and as to price. This is natural and right.

### Let Us Prove Chalmers Quality

We believe, however, that Chalmers cars possess qualities that make them the best value in their price class. We believe Chalmers cars are the best cars for you to buy, and all we ask is an opportunity to prove to you that the things we say about Chalmers cars are true.

In such points as comfort, beauty, convenience, we know that Chalmers cars will compare favorably with even the highest priced. They have all the "features" that modern motorists demand—self-starter, electric lights, long stroke motor, demountable rims, four-forward speed transmission, speedometer, power tire inflater, etc.

### How to Judge Motor Cars

But there are certain other *qualities* which you should demand. You should look for them in all the cars you consider. We ask you to make these qualities your standard in buying any car, whether or not it be a Chalmers.

As you study the cars at the National shows or in the dealers' sales rooms,

compare them not only as to comfort, beauty, convenience and mechanical excellence, but also as to the following points:

1. Stability of company marketing car
2. How long have they been in business?
3. Do they manufacture or merely assemble?
4. What do the owners say about the car?
5. Has the car itself merely features or is real quality built into it?
6. Will it command a good price in case you care to sell it two or three seasons hence?

Consider the prices of cars *only in relation to their quality*. You can pay too little to make a wise investment. You can also pay too much.

### Why Chalmers is Best Value

Here are some specific facts showing why it is to your interest to pay the Chalmers price rather than lower prices. These same facts show why it is not necessary to pay more than the Chalmers price to get the maximum in motor car service and comfort.

Chalmers transmission gears are ground to an accuracy of  $\frac{1}{2}$  of 1 1000 part of an inch. This grinding alone makes Chalmers transmissions cost \$8 more than they would if we did not grind the gears. But grinding means quietness, smoothness, long wear.

The Chalmers crank shaft costs \$5 more than a crank shaft which would do. But one fact that we are proud of is that we have never had a case of broken crank shaft. And so we spend that extra \$5. The Chalmers crank shaft is of the same quality as the crank shaft used in the \$4000 and \$5000 cars.

We spend \$15 more on each Chalmers body than we would have to spend if we used a cheaper material and the old-fashioned straight-sided instead of the full flush sided bell backed design.

Chalmers radiator cost \$5 more per radiator than we actually need to pay to get a radiator that will keep the motor cool. We spend this extra \$5 to buy the best radiator on the market.

We spend \$150 more on our steering wheel to furnish an enameled aluminum spider and a mahogany rim in place of the usual maple rim with a cast or stamped iron spider.

### None Better Than Chalmers

Chalmers steering connections are all drop forgings and are all heat treated. Highest priced cars do not contain better materials.

The mohair which is used in Chalmers tops is the highest grade material on the market. We could save \$10 per car in top material alone and it would require a chemical analysis now to tell the difference. But anybody could tell the difference in a year from now.

We could buy leather for upholstering our cars \$12 per car cheaper than we actually pay. This cheaper leather is used in many cars. You really can't tell the difference until the cars have run a while, and then you can very easily tell it. We spend this difference to secure a high grade, genuine leather.

The Turkish springs in Chalmers cushions cost \$2.50 per car more than the ordinary spiral springs used in most medium priced cars.

### Compare Chalmers with Others

Consider even so small a thing as piston rings. One Chalmers sectional piston ring costs as much to make as an entire set of the ordinary piston rings, even such as are used in some of the highest priced cars.

We mention these few items just to show you that we are making no exorbitant claims when we say that Chalmers cars are genuine quality cars at medium prices. We ask you to remember these things in making comparisons.

See the other cars, but do not buy until you have seen the Chalmers. Compare other cars in the Chalmers price class on the points we have named. We are willing to accept your decision after you have made such a comparison.

Our book "Story of the Chalmers Car" sent free on request, will help you in making your choice.

## Chalmers Motor Company, Detroit

"8" 8 Passenger Touring Car, (6 cyl. 84 h. p.) \$2400

We urge you to see these cars at once at our dealers. Chalmers cars will also be exhibited at the leading automobile shows.

"Tiny 8" (4 cyl. 20 h. p.) 4 or 5 Passenger - \$1200

"8" (4 cyl. 84 h. p.) 7 Passenger - \$2600  
(Price includes full equipment and new 7 x 7 Detroit)

"30" (4 cyl. 30 h. p.) 4 or 5 Passenger - \$1800

## The Trend in Automobile Construction

### The Views of Automobile Engineers and Designers

We believe that certain recent tendencies in design and construction are, for smaller motors, higher speed and more efficiency than ever found in the present type of motor. Motors that would compare with the better design of motors on the other side of the Atlantic, small high speed, highly efficient motors are used. This means that the motor is a vital subject, as the price of gasoline is steadily going up and therefore the economy must be closely watched. And there is a very strong demand for automobiles using a high grade of kerosene or a low grade of gasoline and this is something that must be met and handled by the engine builders as well as the carburetor manufacturers.

CLARENCE T. ROYCE

The electric starter is giving the engineer considerable concern. The electric starter must be reliable self controlled and above all fool proof. It must be possible to crank the engine rapidly and yet as small as possible in size, weight and cost. The charging and lighting dynamo must be one unit with the starting motor or a separate machine must have sufficient capacity to keep the battery fully charged at all times, and must of course be small enough to keep down weight. It becomes evident then that the ideal electric equipment is the combination of the charging and starting motor in one unit, thus giving the engine half the added weight.

**CHARLES BRYDEN Chief Engineer,  
American Motors Company**

The automobile manufacturer is giving his careful attention to the public demands for a comfortable noisless car. Particular attention being given to self starter, the tendency being in favor of the electric self starter.

The manufacturer today is giving greater attention to the analysis of metal used and in most instances specifies his own analysis as he has learned by practical experience that certain analyses give better results for his particular end of work.

**I. J. MOORE,  
Hirsh Electric Company**

**Detroit, Mich.**

First of all the prevalent tendencies in the design of engines are the application of the long stroke and same type of the regulation or sleeve valve to replace the poppet type. In relation to the design of carburetors, which is, of course an important problem, the most important tendency is the adaptation of present successful types to operation with leaner or at least liquid fuels heavier than gasoline. Variations in the design of the valves are also observed, such as the use of the sleeve valve with the poppet of the carburetor for automobile engines. This tendency is also observed on every hand by the widespread interest in the use of all sorts of devices being proposed for using heavier liquid fuels in the design of carburetors. The use of the sleeve valve in the carburetor for heating the mixing chamber either with the hot water from the jacket or with the exhaust

J. A. MOYER,  
Professor of Mechanical Engineering,  
State College Pa.      Pennsylvania State College.

The most vital problem to-day in the gasoline automobile is the necessity of being able to burn the poorer grades of fuel. The greatest want to-day is the ability to burn kerosene successfully in the present automobile engine. The most serious problem to-day is the lack of gasoline 1918 and 1914 will be more serious in this respect than at present.

H. H. BOWEN

Waukegan, Wis.                      Waukegan Motor Company

One of the problems that seems of great and almost imperative importance and in which the requirements for a solution are continually becoming more pressing is, of course, the carburetor and fuel supply.

The difficulties are known but the incentive to remedy them does not seem to be sufficient. Many data are required before the engineer may command this subject. The data are wanting. The defects are known but the remedies not. The law of diffusion of vapors is but little understood, and if it were understood, the engineer does not know what sort of vapors he is dealing with. The relations between the con-

Some years ago the Editor of the SCIENTIFIC AMERICAN sent out a letter to the members of the Society of Automobile Engineers in which they were asked to give their views on present tendencies in automobile design. Through lack of space the Editor was unable to publish all the replies received. Most of the replies were in the nature of criticisms, and agreed on the present tendencies, so that there would be considerable repetition were all the replies printed. It has been deemed advisable to select from the many letters received those which seem to express the views of most designers. In this selection subject matter has been considered rather than the personality of the writer. Many replies were received from members of the SOCIETY OF AMERICAN MECHANICAL ENGINEERS.

huretor and the motor and different speeds of the motor length of the intake pipe and such matters have not been thoroughly investigated.

Detroit, Mich. R. J. MYNARD

The present day demands of the owner driver in the ordinary use of his car are as follows: Electric lighting system, starting motor, magnetic ignition, extreme quietness at all speeds, maximum economy of control maximum fuel saving, the driver's seat, ease of use of minor controls, the ability to completely lock up car, liberal oil storage for hundreds of miles of running.

**Accommodate.**—Top capable of raising and lowering without help and retains level from within. Glass front adjustable from front completely lowered to raise view. Remountable in minutes.

**Chicago, Ill. R. M. NEWMAN**

From the manufacturers standpoint, the present tendencies in design and construction may best be summed up as developing along two lines (a) the more economical use of materials (b) the

By the more economical use of material we mean the use of such special alloys or specially treated materials as shall produce a car which is more durable, requires less attention and weighs less for a given carrying capacity. By the more economical distribution of material, we mean the careful study of design in every part of the car in order that the best material for any particular part shall be used in that part, that no more shall be used than is requisite to have it perform its due and proper functions.

**Flint, Mich.** **A. P. BRUSH, Consulting Engineer,**  
**General Motors Company**

As to present tendencies in carburetor design. In Europe they have done away with the spring air valve and all have all the air entering past the point of fuel flow. This tendency is being widely felt in this country and the makers are gradually coming to this type. The problem is demanding carburetors which start easier and keep on running even after motor and carburetor are very cold.

GEORGE M. HOLLEY *President,*  
Holley Brothers Company

The latest field for experiment on the part of the engineering department is demountable wire wheels. It is the writer's opinion, however, that this foreign feature will eventually consist of non-demountable wire wheels, fitted with demountable rims for quick detachable tires, because the expense of additional spare wheels, as well as the weight more than compensates for the advantages resulting from the use of wire wheels.

Among the advantages of wire wheels compared with wood or pressed steel wheels, are increased tire wear, due to the resiliency of wire wheels, and improved appearance of the car. The subject of braking all four wheels has been

discussed a number of times by American engineers, but has not found favor in this country and is losing favor abroad.

Relative to bodies, the growing tendency is for straight line flush side construction with a stream line effect in order to reduce wind resistance to a minimum.

New York, N. Y.                      JOSEPH A. ANGLADE

I feel that the present tendencies in design and construction, if left to the manufacturer would be simplification of parts and ease of assembly. The demands of the public, however, preclude the possibility of working very far in this direction.

There seems to be a tendency to use wire wheels. I hardly think that the demand for this, however is caused by any trouble that the wood wheel has given but it is due more to a desire for something newer. It is a fact however, that some of the larger concerns in England are putting more than half of their product on wire wheels.

(A. TRANK (Per R. F.), Assistant General Manager,  
Indianapolis. Henderson Motor Car Company

It seems to me that the most vital problems are the development of engines and carburetors to use kerosene and alcohol successfully—a simple and successful substitute for the poppet valve—the proper design and lubrication of small bearings and Hubert's design.

It seems to me that with the substitution of a simple and successful sleeve or rotary valve, the addition of means for using a heavy fuel, and adequate protection and lubrication for small wearing parts, the present moderate-priced machines would be all that could be desired.

D W SMITH, Member S A N.  
Washington D C  
Brook. Beeken & Smith

The present tendencies in design and construction are toward quietness, simplicity of arrangement of parts, luxuri-

The public demand is for higher powered cars, 6 cylinders, electric lighting, easy riding, full equipment and accessibility.

The demands of the public must be met by decrease in the cost of production without sacrificing the quality of the cars produced, better design from the standpoint of the engineer.

The vital problems in automobile construction are those affecting the maintenance of the car such as carburetors, transmission, wiring, lubrication and tires.

Every concern should pay special attention to the establishment and maintaining of a properly equipped laboratory under the supervision of an engineer who has been thoroughly trained in the theory and practice of motor car construction, both at home and abroad.

W C MARSHALL,  
Assistant Professor of Machine Design,  
Sheffield Scientific School of Yale University  
New Haven, Conn.

The tendency of the automobile construction at the present time, appears to be the substitution of spline shafts for square

shaft is transmission boxes. This is desirable, in a general way provided the making of the shaft and the gear is carried out on correct lines, that is, the spline shaft should be made so that the surfaces between the splines run true with the bearings, and then the hole in the gear could be ground to proper diameter to fit this shaft at its smallest diameter.

There is a tendency among some of the manufacturers to have the gear make contact on the tops of the splines, because this surface can be easily machined by putting the shaft in a plain grinder and grinding the tops of the splines after the shaft has been hardened or heat-treated.

The ideal way, we believe, is to finish the spline shafts accurately between the splines either by a second milling operation or by a grinding operation, and then design the gear to fit on this surface and not fit on the form of the splines. The

By use of this machine, more work at the same speed is the assured. By so doing, the gear can be ground to accurate diameter on an internal grinding machine and perfect fits are sure, together with accurate workmanship and quiet running operation.

**WHEELER, HARRIS** **JAMES M. HARRIS,**  
The Harris Machine Company

Leave comfort, convenience and beauty lines to *her*  
—she is leaving the price and mechanical correctness  
to *YOU*

*This is the Cole "50" Delco Electric Starting  
Touring Car—the choice of American womanhood*

**\$1985**

**MAKE** the purchase of your next motor car a domestic business transaction. Recall how you and the wife built the home? You bought the lot where values were right and selected the architect on the strength of his reputation. You watched the plumbing—you planned the heating plant. You demanded nothing but "bests" in the entire construction.

You left the social environment, the convenience and the interior decorations to her—this was *right*. When it was all done two things had been satisfied—a woman's intuitive appreciation of beauty and a man's cold business judgment. It's a combination that can't be beat—take it with you when you go to buy your next motor car.

The character study of the Cole Motor Car at the top of this advertisement is for her eye—not yours. Dry tabulated specifications are for you and you alone. After careful investigation of the Cole and other cars as well, your preference will be—

The New Series 8—"50"

### Its Principles of Construction

Silent Cole unit power plant with three point suspension and all working parts enclosed. A motor free from grease cups, with automatic lubricating system and combination thermo-siphon and force pump water circulation. Timken front and full-floating rear axle with large Timken bearings. Large brake drums on wheels equipped with Firestone demountable rims, 122-inch wheel base. Gasoline pressure tank and tire rack in rear. Straight line body with conformed blades and locks. Deep Turkish, hand buffed leather upholstery. Silk mohair top. Clear vision ventilating windshield and speedometer with grade indicator. Solar electric lamps—nickel-silver trimmed. Price for Cole "50," completely equipped, \$1985.

In addition to the "50" the Cole comes in two other classes: Cole "40," 116-inch wheel base, price, completely equipped, \$1685; and the Cole six cylinder "60," price, completely equipped, \$2485.

*No difference in quality—merely diamonds of varying karat*

# Vitalized Rubber calls a halt on "Short Mileage!"

At last science gives you more rubber shod mileage.

## Diamond (No Clinch) Tires

now made of VITALIZED RUBBER—a scientific combination of pure rubber and a toughening compound.

**A perfect 3-Point Rim Contact tire at last**

## You can get Vitalized Rubber in Diamond Tires—NOW

A tire containing too much rubber fails to give the necessary mileage because it is not tough enough to withstand road usage. And the tire containing too little pure rubber has not the necessary staying qualities.

Our chemists have discovered the secret of how to mix pure rubber and a toughening compound in just the right proportions. The result is additional mileage for you. The pure rubber we use comes direct from the trees of the tropics—it is fresh and contains all the vitality of youth—it is elastic and easy riding. Then we mix this pure rubber with the secret toughening compound, which gives it the necessary vitalizing, wearing, *more mileage* quality.

This scientific combination has been vainly sought after for years by tire makers. After 15 years of successful tire making we have solved the problem—and you enjoy the benefit of our really wonderful discovery—in "Diamond" Vitalized Rubber Tires.

Add to this the Diamond proven principles of proper construction—nothing inferior in rubber, fabric or workmanship—and you have as perfect a tire as money can buy.

Here is a combination of easy riding and more mileage advantages you can't get in any other tire today—*Vitalized Rubber, Perfect 3-Point-Rim-Contact, No-Pinch Safety Flap*, and, if you wish, the now famous Safety (Squegee) Tread—made to fit all types of rims.

So this time specify "Diamonds"—you can get them at any one of the

# 25,000 Diamond Dealers

always at your Service

**NOTE**—If you are not actively satisfied with the mileage you are getting now—if you wish to reduce your tire upkeep—send today for our new book, "How to Get more Mileage Out of Your Tires." It is free in every tire user's mailbox. You simply cannot afford to be without this valuable book, so send this coupon today.

Fifty per cent of all tires are ruined through lack of perfect rim contact.

Perfect 3-Point-Rim-Contact is just as big an advantage in tire construction as 3-point suspension in the automobile.

Diamond 3-Point Rim Contact Tires hold with a vice-like grip absolutely preventing the tire from breaking above the rim, insuring no rim skid—no rim cutting—no rim trouble at all.

Our engineers have mastered the principles of Rim Contact construction, and you can get the Diamond (No-Clinch) Tire, with a perfect 3-Point Rim Contact—an important advantage that has been overlooked by all other tire makers.

## No-Pinch Safety Flap absolutely protects the inner tube

The No-Pinch Safety Flap that comes in every Diamond (No-Clinch) Tire will cut your inner tube bulks in half—because it forms a substantial wall separation between the inner tube and the rim, making it impossible for the inner tube to be pinched or cut under the rim, or injured by rim rust.

This No-Pinch Safety Flap is made of the best grade of fabric, and is finished with a "F. other Edge" as a further protection against inner tube cutting.

There is no rubber in this flap to adhere or vulcanize, so that the inner tube can be quickly and easily removed at all times—another big Diamond advantage.

## Mail This Coupon TODAY

Among the devices made in America which have proven successful, mention must be made of the Universal, Holley, Hart-Darr (tractor), Twombly, International Harvester (tractor), Stumey (tractor), Gas Tractor (tractor), Mota & Wotan (stationary), Hornby-Akroff, Dell Verge (stationary). A number are still in the experimental stage.

In his experiments, Mr. Holley has

found that a Ford car fitted with his device will give 20 miles a gallon on kerosene and 32 on gasoline as bought at random in Detroit. This is a per mile cost of 0.25 cent for kerosene and 0.6 cent for gasoline (based on 10 and 20 cents). Mr. Holley states as a result of several years' experimentation in this line that he believes "the kerosene carburetor will be used largely in the commercial line, such as delivery wagons, motor trucks and commercial boats at an early date. As to motorcycles and pleasure vehicles, it has a future but gasoline will be used for a considerable period."

The makers of the Universal state in their guarantee that "The device will give a greater range of speed control than cold gasoline and a range equal to hot gasoline, that it will give from 10 to 15 per cent more power a pound of fuel on kerosene than on gasoline, and back up both claims."

These instructions and the foregoing seem to show that there is a big future in kerosene as an automobile or internal combustion engine fuel, and that its use is not far away, nor will it entail an great amount of change in existing motor cars, other than the substitution of a suitable vaporizer.

International Champion  
and Stock Champion

National "40" in Spain

**National "40"**

**Luxury - Reliability - Service**

Wherever you go, you'll be proud of your *National*. It is the result of twelve years of concentration upon the harmonious combination of beauty, luxury and reliable service.

Every advanced idea, every requirement mechanically, every refinement tending to your comfort, ease and confidence, is in these Five *National* Models, Improved Series V, \$2750 to \$8400

Semi-Racing Roadster, Speedway Roadster, Five and Seven Passenger Touring Cars and Tux Tonneau—Limousines, Coupes and Sedans

Long Rider (17 x 7) flexible and delicate Motor with standard V-8  
Left Side Drive  
Center Control  
Gray & Davis Electric Starter easily operated by simply turning a button within reach  
Gray & Davis Dynamo Electric Lighting System  
Beach dual double headlights  
12 volt Turkish Underbody  
Full heavy nickel trimmings  
Electric Horn  
Powerful and reliable brakes  
Rearview Interior  
Adequate Baggage-Carrying Compartment concealed in body but easily accessible  
Tire Pump, Integral part of motor. Inflates a tire in three minutes.  
Traction-Enhanced Shock Absorbers in rear 10-inch Wide Base.

Adjustable ventilating and rain vision Wind Shield  
Multiple Jet Carburetor  
Horn for nearly lead speedometer  
Tire Carrier in rear  
Full Running Rear Axle  
Rear Motor Tires, Cover and Caster  
Rearlight Assembly—84 Blipits, in rear  
Rear Motor Tires, Cover and Caster  
Large gasoline pressure-foot Tank with Gauge in rear  
Kick Start and Fuel Stop  
Road Mail in Running Board  
Plain continuous enclosed Metal Guards.  
Rearview mirrors, universal  
Climax System demonstrated to its only perfect riding system  
Tools, in concealed tool box under applier

The best car to own — write us for proof

National Motor Vehicle Co., — Indianapolis, Indiana

EVERY COLLECTOR IN AMERICA WILL BE INTERESTED IN THE SERIES OF ARTICLES TO APPEAR EACH MONTH IN THE PAGES OF THIS MAGAZINE. ARTICLES UPON SUBJECTS WHICH WILL PROVE A DELIGHT TO AMERICAN COLLECTORS

**THE NEW  
COLLECTORS' DEPARTMENT**

**AMERICAN HOMES  
AND GARDENS**

WELCOME CORRESPONDENCE AND LETTERS OF ENQUIRY FROM ITS READERS ON ALL SUBJECTS CONNECTED WITH COLLECTING OLD FURNITURE, POTTERY AND PORCELAIN, CARPETS, PRINTS, ENGRAVINGS AND STITCHING, GLASS, FABRICS, BEADS, PEWTER, SILVER, OLD JEWELRY COINS, MEDALS, MINATURES, IN FACT WITH ANYTHING APPEALING TO THE AMERICAN COLLECTOR. THE EDITOR OF THE "COLLECTORS' DEPARTMENT" WILL BE GLAD TO FURNISH INFORMATION ON ANY SUBJECT CONNECTED WITH COLLECTING. ENQUIRIES SHOULD BE ACCOMPANIED BY STAMPS FOR REPLY. ANY PHOTOGRAPHS OF OBJECTS ACCOMPANYING LETTERS WILL BE RETURNED TO SENDERS IF REQUESTED.

Subscription price of AMERICAN HOMES AND GARDENS is \$3. a year

has accumulated rubber to be used in the products for which it is intended.

For calendaring rubber, a machine called a rubber calender is used. This machine is made with three and sometimes four heavy rolls, capable of very fine adjustment. The rubber from the green-stock storehouse is first warmed up on a small mixing mill and is then fed between the rolls of the calender, coming through in a thin sheet of required thickness, and is wound up in a layer cloth and sent directly to the departments, where it is used for inner tubes, druggists' sundries, etc., where only rubber and no fabric is used. Where the rubber is to be applied to fabric, the fabric is put through the calender rolls with the rubber, and the rubber is literally ground into the fabric. Fabric thus treated is known to the trade as friction, and is generally used in the manufacture of pneumatic tires, belting, hose, etc. For boots, shoes, and other special work, calenders are used which are equipped with rolls engraved with the shapes of the shoe and other parts of the articles in question, so that the sheet of rubber coming from the machine has imprinted on it the shapes and thickness of the articles for which it is intended.

After passing through such of the processes described as are required the rubber is ready to be made up into the various articles known to the rubber trade, such as boots and shoes, mackintoshes, waterproof fabrics for balloons, aeroplanes, tenting, etc., mechanical goods such as rubber heels, horsehoe pads, jackknives, tilting automobile and other pneumatic artificial feet, belts, etc., druggists' sundries, such as nursing bottles, nipples, or rings, bulbs, hot water bottles, tubing, etc., tobacco pouches, rubber baiting, golf and other balls, insulated wires, and garden hose, inner tubes, tires and the many other commodities into the manufacture of which rubber enters. As this article has to do more especially with the manufacture of automobile pneumatic tires, we will omit the various methods used in the manufacture of the numerous articles mentioned above and pass directly to the manufacture of pneumatic motor car tires and inner tubes.

When the first pneumatic automobiles were made in any quantities the tire used was of the single tube type and fastened to a crescent shaped rim by means of lugs or bolts, and cement. This proved very unsatisfactory, and the clincher tire, using an inner tube, then came into prominence as an automobile tire. With some variations in design, this type of tire still continues to be very popular, but during the growth of the automobile industry, the so-called straight-aided or detachable automobile tires have been developed, and have come into favor. Some of the latter type of tire are of the regulation lining type, others being somewhat different. Most all of these so-called straight-aided tires have wires in the beads to keep them from flying off the rim. With the development of the motor truck industry, solid tires have come to be used where heavy loads have to be carried. This type of tire has been developed from the original wagon tire to the present various types of improved motor truck tires, and so-called high efficiency solid tires, of peculiar design, to give the desired resiliency and wearing qualities.

**The Birth of an Automobile Tire.**

From the calender room of the rubber factory, the stock is received in the automobile tire department, in the form of large rolls of rubber coated fabric, and in rolls of sheeted rubber of various thicknesses and widths. The rubber coated fabric is first cut into strips of proper width so that the edges will extend from head to head over the crown of the tire. These strips are always cut on the bias, generally at a 45-degree angle, with the edge of the roll, and were formerly all cut on a cutting table, a table about 80 feet long and 6 feet wide covered with sheet metal. The cutting was done by two men, each having a knife and each cutting half way across the cloth along

the edge of a straight-edge so arranged as to be always set at 45 degrees with the edge of the tire. Gradually this method of setting is being put aside by the use of the bias cutter, an extremely up-to-date machine having jaws which ride up to the end of the fabric and pull it for a certain distance under a knife set at a 45-degree angle, the knife being set to cut just when the jaws have arrived at the limit of their travel. The action is repeated so that the machine cuts about eighty strips a minute. These strips are fed onto a series of belts which carry them to where they are placed, by boys, in a book having a set of cotton cloth between each strip of gum fabric, to prevent the strips from sticking together.

The majority of automobile tires today are built by the hand method, and in this process the books of fabric are laid up and spliced into proper lengths to go around the tire and allow a proper lapping for the splices. The proper number of these laid up pieces, or plies, as they are called, are placed together with cotton cloth between and taken to the tire builder. The tire builder mounts the core, upon which the tire is to be built, on a guiding stand, generally consisting of a wheel with a tire of rubber which is so that the first ply of fabric will slide in place. The first ply is then stretched onto the core and spliced, rolled down with a hand roller onto the sides of the core, and trimmed with a knife at the ends. The following plies are put on and rolled down in the same manner, the beads being put at the proper time, according to the size and the number of plies to be used. After all the plies have been put onto the core, the so-called cover rubber is put on. This cover rubber is generally a sheet of rubber about one sixteenth of an inch thick or more and of the same compound as the rubber on the fabric.

In the case of the machine built tire, the result is the same, but the work is handled as follows. After the rubber cover fabric has been cut on the bias cutter, the strips are spliced and rolled up in rolls on a spindle which is placed in the so-called tire building machine. The tire core is mounted on a stand attached to the machine so that it can be revolved by power and the fabric is drawn onto the core from the spindle under a certain definite tension. The tire machine rolls the fabric down by power, and the beads are put into place before the tire and core are removed from the machine. Thereafter the process is the same as in the case of the hand-built tire.

After the cover rubber is in place the tire is ready to have the tread applied. The tread is made up independently of the tire by laying up narrow strips of rubber, in different widths, in such a way that the center of the tread is thicker than the edges. In the case of the so-called single curve tire, which are wholly vulcanized at one time, this tread is applied to the tire directly after the cover, a strip of fabric called the breaker-strip, generally being placed underneath, and the building of the tire is completed.

#### How the Tire is Cured.

In the general method of curing, the tire is allowed to remain on the core, and is either heated up in a mold and put into an ordinary heater or it is laid in a mold and put into a heater press where the hydraulic pressure keeps the two halves of the mold forced together during the vulcanizing process. After the vulcanizing is completed, the tire is removed from the mold, the inside is painted with a French mixture, the tire inspected and cleaned, and so made ready for the market. In some methods of curing, the tire is put into a so-called toe-mold, which is really a pair of side flanges, reaching up only as high as the edge of the tread on the sides of the tire. After the flanges are fastened into place, the whole is cross-wrapped, the cross-wrapping coming in direct contact with the tread. The tire in this condition is then put into the heater and vulcanized, giving the so-called vulcanized tread tire. Such another strip of applied is so infinite a kind of another "break" job inside the tire and placed

the whole in a mold. This is known as the air-bag mold process.

From the case of the single curved tire just described, we will take up the case of the so-called double curve tire, in which the tire receives two separate vulcanizations. In this system of tire manufacture, the tire carcass is semi-vulcanized before the tread is applied. This first vulcanization is always done with the tire on the core and either heated up in a mold or cured in a mold in a heater press, the period of vulcanization being only long enough to partially cure the rubber. The tire carcass is then taken from the mold and mounted on a buffing machine, and that part of the cover which is to be covered by the tread is buffed to a rough surface, which is then given one or more coats of rubber cement, allowed to dry, and the tread, which is generally made of some quick curing compound, is then applied in the green state. The tire is cross-wrapped, either by hand or by a cross-wrapping machine, placed in a regular heater and given the second cure. This second cure is timed to complete the cure of the carcass and also to completely cure the tread. After removal from the heater, the cross-wrapping is stripped from the tire, the tire inspected, the inside painted, and so made ready for the trade.

Authorities differ as to whether the integral construction or single curve method or the so-called two-mold process be the better results. Advantages of both systems are able to advance strong arguments in support of their respective methods.

#### The Three Kinds of Inner Tubes.

Inner tubes for pneumatic tires may be classed under three headings, according to the method used in their manufacture, namely, seamless tubes, rolled tubes, and tube machine tubes. By far the greater number of tubes come under the first two headings. For seamless tubes, the rubber is taken from the vulcanizer in the form of sheets, or sheets of about 48 inches in thickness. These sheets are cut into strips of proper length and just wide enough to make a tube of proper cross-section diameter when the two long edges are folded over and fastened together with rubber cement. These two long edges are put on a bevel so that they make a good lap seam. The tube is then pulled over a mandrel of proper size and a thin piece of wet cloth rolled around it and then it is spirally cross-wrapped with a long narrow piece of wet duck, for its entire length. The whole is then put into a regular heater and the tube vulcanized. After vulcanizing the wrapping is removed and the tube stripped from the mandrel, turning the tube inside out, so that the smooth side which was vulcanized next to the mandrel appears outside. The rough side showing the marks of the cross-wrapping, is inside. The valve hole is then punched in the tube, the valve inserted and the open ends of the tube buffed down to a feather edge. The tube is then strung across to the rollers, who cement the buffed ends and splice them together, placing one open end within the other making a lap joint over the tube about 2 1/2 inches long. The compound used in splicing is generally cured by an acid which chemically vulcanizes the rubber without the application of heat. The tube is then finished and ready for the market. Rolled tubes are made from very thin sheet rubber by rolling the same over a mandrel of proper size, until the required number of layers of thin rubber have been rolled on to give the tube the desired thickness. The tube is then wrapped, cured, and spliced, in exactly the same manner as a seamless tube. Tube machine tubes are run from a tube machine exactly like wagon tires, except that the die is used which permits the rubber to flow out in tube form. This tube is then pulled onto a mandrel, wrapped, cured and spliced, the same as the seamless and rolled tubes.

## Quality Equipment for Automobiles

# GRAY & DAVIS

Electric Lamps  
Lighting Dynamo  
Electric Starter

**GRAY & DAVIS products offer maximum efficiency. They add so much to safety, convenience and efficiency, that you cannot afford to disregard this equipment when purchasing a car.**

#### ELECTRIC STARTERS (6 volts)

Positive in operation. Remarkably power full. Requires but a 6-volt battery which is charged automatically without expense by the dynamo. Will "split" engine 1 1/2 hours, power a car 2 miles.

#### LIGHTING DYNAMO

The small, compact machine is driven by the engine. It lights lamps, charges batteries and furnishes current for the electric Starter. In use over four years. Thoroughly reliable.

#### ELECTRIC LAMPS

GRAY & DAVIS Lamps offer the highest type of automobile illumination. They are powerful and brilliant, and greatly add to appearance and safety.

As a car owner, or prospective owner, you may be interested in knowing that over thirty of the leading manufacturers of America and Europe have adopted GRAY & DAVIS equipment for 1918. Undeniable evidence regarding the high quality of these products.

If you would learn the real pleasure of motoring, purchase an automobile equipped with GRAY & DAVIS Electric Lamps, Lighting Dynamo, Electric Starter, or all three in combination.

Write for information.

## The "32" Coupe

A distinguished addition to a distinguished line

First View, New York Motor Show Jan. 11/18

In exterior appearance, the Hupmobile Coupe is as unobtrusively unique and as well balanced as the other models of the "32" line.

In interior finish and appointment, it is rich and luxurious—equipped Bedford Car upholstery, with seat walls to match and ceiling done in heavy satin with right hand control and seats for those who sit in comfort.

The coupe runs on the line of Hupmobile pleasure cars, which includes two touring models and a standard all built on the same sturdy "32" chassis, and the well known "20" Runabout.

The entire line will be displayed at the New York and Chicago shows.

Inspect the car there at any other show.

Write to Hupmobile for literature. The Gray & Davis name is the Hupmobile name.

### Special Resources of American Libraries

EVERY scholar will welcome with enthusiasm the latest publication of the United States Bureau of Education, "Special Collections in Libraries of the United States," compiled by W. H. Brown Johnson, Librarian of Columbia University and Leonard G. Mudge, reference librarian of the same institution.

Intercollegiate books are the bone of every seeker after knowledge. The special bibliography only half solves the problem. The time will come when no special bibliography will be considered wholly satisfactory unless it contains in connection with the title of every rare book a list of the libraries in which the book is to be found, or if this imposes too much labor upon the bibliographer, unless at least one copy of the book is thus located. With this improvement coupled with the modern system of interlibrary loans the bibliographic millennium will be pretty nearly attained.

Feeling such a commendation a hand book similar to that just published by the Bureau of Education is an admirable makeshift. Here we find a list of libraries in which each department of knowledge is most fully represented, with sundry particulars as to the strength of each collection along a particular line.

To illustrate with a few out of the way topics. If you are looking for the literature of philately, you find, by way of the index, that the Pittsburgh Carnegie Library has a philatelic collection of 342 books, pamphlets and periodicals devoted in trust to the American Philatelic Society, while the Boston Public Library possesses 210 works on the same subject. If you wish to investigate chess (r) the Library Company of Philadelphia. This institution is the depository of Prof. George Allen's chess Library, containing 1070 volumes, besides newspaper clippings, manuscripts, and pictures relating to the game. The literature of the winning industry is represented by 750 volumes in the New Bedford, Mass., Free Public Library. The Berkshire Athenaeum, at Pittsfield, Mass., has a collection of all dramas of agricultural fairs. Cornell University Library has a Petrarca collection of 3,700 volumes, and a Dante collection of 7,000 volumes (exceeded in importance, if at all, only by the collection in the Biblioteca Nazionale in Florence). Williams College Library has 162 volumes relating to Phœbus. Harvard University has a collection of Yiddish literature numbering 4,800 volumes and 1,500 pamphlets. The Atlantic Library of Cedar Rapids, Iowa, has the most important collection in the United States on Freemasonry and related topics, which in 1908 numbered about 15,000 volumes, of which 5,000 were in foreign languages. The Library of the Supreme Council of the Ancient and Accepted Scottish Rite of Freemasonry, in Washington, has a collection of about 1,000 volumes on Masonic and allied subjects. And so on.

## YOUR NEW ELECTRIC

### See that Your Pleasure Car or Truck is equipped with the Westinghouse Motor

THE automobile you can use upon every occasion and in all weathers, and that comes first to meet your requirements during eight rainy, muddy and snowy months in the year, is the electric.

The motor of the electric is the most dependable piece of machinery ever devised, and built as all Westinghouse Motors are built need never cause you a moment's thought.

The cost of running an electric is negligible in comparison with other cars. With Westinghouse

Motor equipment and reasonable care you may depend upon your electric vehicle to give you years of perfect service.

When you insist upon the Westinghouse Motor you assure yourself all the newest and most approved features of electric vehicle motor construction; a strong, powerful motor with comparatively light weight, full protection from dust and mud, no undue drain upon batteries.

For business delivery and trucking there is no more dependable transportation than that given by the electric equipped with Westinghouse Motors.

We will be glad to give you any special information about electric vehicles for any purpose upon request. The names of all electric equipped with Westinghouse Motors may be had for a post card.

## A Little Detective on a Great Machine

Accuracy is the basic principle of the Remington Adding and Subtracting Typewriter (Wahl Adding Mechanism)

Write, Write and Adding

The machine is accurate. But this is not all. It enforces accuracy on those who use it. Likewise it *advises* to accuracy all those on whose work it affords a check.

It detects errors. Likewise prevents errors. Fewer errors are made in every office where the

## Remington

Adding and Subtracting Typewriter

is used. Why? Because every clerk knows that this machine will infallibly detect his errors and this knowledge makes him more careful in every thing that he does.

Thus the machine adds accuracy to mechanical labor saving in every kind of work where writing and adding are done on the same page.

# WASTE EFFORT

Look around your office—are your clerks wasting your profits doing work by hand that can be done in a fraction of the time with a machine—

## Addressograph

PRINTS FROM TYPE

A clerk busily engaged pushing a pen may be doing brain work or monotonous drudgery—you can't tell. Dig deeper—did out what your clerks are doing—are they buying brain power, not hand power, from them. And they don't like to write and rewrites names and addresses by hand more than you will want to pay for doing this work by hand when you find out how much it costs. Your clerks are worth about 10¢ a day to you while so occupied.

Your best clerk can write 800 to 1,000 addresses per day. An office boy, with the ADDRESSOGRAPH, can print an equal number in less than half an hour. And the ADDRESSOGRAPH can be used not only for addressing envelopes, circulars, letters, etc., but also for filling customers' names in on statements and bills—printing employer's names on time clock cards, pay envelope, pay checks, piece work tickets, pay-roll sheets and other forms—addressing shipping tags, dividend checks, notices, and, in fact, everything frequently addressed to a regular list of names.

### Let Us Show You How To Eliminate Waste Effort In Your Office

Tell us about the list of names you frequently address. Send us samples of your forms. Tell us how many you have on your list. Then we can prove to you in dollar and cents just how profitable the ADDRESSOGRAPH would prove in your office.

### JUST PUBLISHED

## SCIENTIFIC AMERICAN REFERENCE BOOK EDITION OF 1913

It contains 608 pages and 1200 illustrations in a substantially bound in cloth and the cover carries a special design printed in three colors

Alfred A. Moephren  
Consulting Editor for Part I. Industrial Information. Consulting Editor for Part II. Scientific Information.

The editorial staff of the Scientific American receives annually over fifteen thousand inquiries, covering a wide range of topics—no field of human achievement or natural phenomena is neglected. The information sought for in many cases cannot be readily found in text books or works of reference. In order to supply this knowledge in concrete and usable form, two of the Editors of the Scientific American have, with the assistance of trained specialists, produced a remarkable Reference Book, containing over seventy-five thousand facts, and illustrated by one thousand engravings, for which the entire world has been scoured. Immense masses of government material have been digested with painstaking care with the collaboration of government officials of the highest rank, including cabinet officers, and assisted by competent professors of world-wide reputation.

Owing to the printing of an edition of 10,000 copies, we are enabled to offer this book at a merely nominal price. The purchase of the book is the only adequate way to judge of its merits. An elaborate circular, showing specimens of illustrations, together with four full-size sample pages, will be sent on request.

## Making Deliveries Efficient

Every dollar invested in delivery and shipping equipment must pay interest, or show a loss. Are you positive that you are getting the proper returns from your investments?

Where trip sheets and other checks depending upon human accuracy, are used there are big leaks as the Servis Recorder has repeatedly proven—Mechanical supervision is always more economical than human supervision.

## The Servis Recorder

is an instrument that never fails to give an accurate record of a vehicle's work or non-work.

It is absolutely tamper-proof—it is a self-contained device not connected with the running gear of a vehicle in any way neither is it connected with the engine of a motor truck.

It will give you a complete check upon the time required in loading and unloading.

It will tell you the exact time consumed by a vehicle in going from place to place.

It will increase the efficiency of your delivery and trucking service.

It will raise the standard of excellence of your employees.

It will give you accurate data for your cost system.

We have power proof to offer you of specific instances where the Servis Recorder has saved many dollars for those upon whose vehicles it has been installed.

We have letters from firms who state that the use of Servis Recorders has saved them the cost of a new motor truck.

One department store handles 25% more deliveries with 33% less equipment by the use of the Servis Recorder.

Two are companies each saved the cost of a new truck by the use of Servis Recorders.

The delivery efficiency of a large packing house was increased 25% by the use of Servis Recorders.

We will gladly lay these cases, together with indisputable evidence of numerous others, before any use of vehicles, whether horse-drawn or motor driven.

We will welcome the opportunity of showing how the Servis Recorder will effect a saving for you, no matter what your delivery problems may be, or under what conditions your vehicles operate. Will you allow us the privilege of sending you our printed matter?

### The Service Recorder Company

2225 East 105th St.

Cleveland, Ohio

The Servis Recorder has been purchased by more than 30 railroads, for use on switching and transfer locomotives.

## MOTORISTS!

Save Time, Trouble, Expense Master  
Your Motor. It's Easy If You Read

## The Modern Gasoline Automobile

Its Construction, Operation, Maintenance and Repair

By VICTOR W. PAGÉ, M.E.

Covers Every Phase of Modern Automobile Practice Latest and Best Treatise  
Over 700 (8 x 9) Pages TEN LARGE FOLDING PLATES 500 Illustrations

Price, \$2.50

The latest and most complete treatise on the Gasoline Automobile ever issued written in simple language by a recognized authority familiar with every branch of the automobile industry. Free from technical terms. Everything is explained so simply that anyone of average intelligence may gain a comprehensive knowledge of the gasoline automobile. The information is up-to-date and includes in addition to an exposition of principles of construction and description of all types of automobiles and their component, valuable money-saving hints on the care and operation of motor cars, propellers, valves, valves, valves and other types of latest motor. In treating the theory to favor more power transmission, internal application of magnetic induction, development of automobile electric-lighting systems, shock absorbers, steering chassis, application of practical self-starters, long stroke and offset cylinder motors, latest automatic lubrication systems, electric chains for valve operation and change-over switching the use of front wheel brakes and many other detail refinements.

By a careful study of the pages of this book one can gain practical knowledge of automobile construction that will save time, trouble and worry. The book tells you just what to do, how and when to do it. Nothing has been omitted on detail has been omitted. Every part of the automobile is explained, accessories, tools, you plan, spare parts accessories, etc., are in any way interested in the modern gasoline automobile this is a book you need to read.

THIS BOOK IS SUPERIOR TO ANY OTHERS BECAUSE IT IS RIGHT UP TO-DATE AND COMPLETE IN EVERY DETAIL

Not too Technical for the Layman—Not too Elementary for the More Expert

*This is the Republic Rubber Company's New Cylender Room*

## Where machines and brains make tire mileage for YOU

Republic Staggard Tread Tires give you the mileage you really ought to get because their foundation is *right*.

The foundation of a tire consists of alternate layers of fabric and rubber. And the efficiency of any tire depends to a great extent upon the manner in which the fabric and rubber are treated and combined.

The illustration above shows the Republic Cylender Room—the new “rolling mill” of this rubber plant where foundations for Republic tires are made.

In this great room man's skill and ingenuity and modern machinery combine to make the *right* foundation for Republic Tires. Scientific, painstaking care is exercised in every operation from testing and drying the fabric to cylendering (‘‘rolling’’) the rubber and combining the two under proper heat and pressure.

And on this *right* foundation is put the Staggard Tread—the tread of extra thickness that leaves the full-thickness plain tread after the center studs eventually wear off.

The Staggard Tread is protection against skidding, and really economical because of the extra mileage it gives you.

Write today for beautiful folder on this wonderful new Cylender Room.

# What Shows Don't Show

By R. F. Olds, Designer

You'll see the new model of Reo the Fifth at your local Automobile Show.

It will strike you as beautiful, luxurious, roomy—having every final touch.

But here are things you can't see. And they mean, in the end, more than all that shows.

## Tire Mileage

Tires on a car form the chief item in upkeep. Tire saving means more than all other savings together. Every old motorist knows this.

So this year I add 30 per cent to my tire cost, to add 65 per cent to the average tire mileage. I give you tires 14,811 miles. Compare them with rival cars.

The usual tires on this type of car would more than double your tire cost, so tire makers say.

## No Possible Flaws

The steel in this car is twice analyzed, to make sure it is as good as with my costly require ments.

The gears are tested in a crushing machine, to prove that each tooth will stand 75,000 pounds. This test is usually made with light hammers.

The springs are tested in an other machine to stand 100,000 vibrations.

I use in this car 190 drop forgings. The average cost is twice that of steel castings.

But they give me lightness and strength. And hidden flaws can't occur in drop forgings.

The various parts of this car get a thousand inspections. Thus all the uncertainties are completely eradicated in building this Reo the Fifth.

## No Broken Bearings

I use in this car 15 roller bearings. 11 of them Timken. 4 Havill High Duty.

They cost five times as much as the usual ball bearings. But good roller bearings don't break under strain.

## No Overtax

It is the sudden shock which shows up a car's weakness, and the ordinary tests. And sudden shocks will come.

To withstand them, I give to axles and driving parts 50 per cent over capacity. I have made them all ample for a 45 horse power car.

To prove them out, I ran one of these cars for 10,000 miles, at top speed on rough roads. I met at the worst every possible road shock, and not one important part gave out.

I use 14 inch brake drums. I use 2 inch, 7 leaf springs. I use costly axles—chromium nickel, vanadium, manganese—all to ward off an overtax. I place cost below safety in this Reo the Fifth.

## No Troubles

That isn't quite true. All machines have their little troubles. But I've gone to the limit to save trouble with this car.

Each engine is tested 20 hours on the blocks, and 28

hours in the chassis. There are five long continued tests.

My carburetor is doubly heated—with hot air and hot water—to save the troubles with low grade gasoline.

I use a \$75 magneto to save ignition troubles. I use a centrifugal pump, instead of a siphon, to insure the water circulation. That costs about \$10 extra.

Cars are built slowly and carefully, parts ground over and over. I limit my output to 50 cars daily, so nothing shall be slighted.

## No Skimping

To make the car show my minute pains, I give equal care to the finish.

The body has 17 coats. The luxurious upholstery is of

genuine leather, filled with the best curled hair.

There are three electric lights, and the dashboard lights are flush. And the whole car, even under the hood, is fully nickel trimmed.

## Center Control

Our center control is extra save to this car. All the gear shifting is done by one small handle, completely out of the way. It is done by moving this handle only three inches in each of four directions.

Both brakes are operated by foot pedals. So no levers at all clog the way of the driver. And this permits of the left side drive.

No other center control will please a man who once discovers this.

## Add \$200 to My Cost

These extremes I figure add to the necessary cost of this car.

They cut down our profits. They force us to factory efficiency. They compel us to build every part ourselves. And to minimize cost we build only our chassis.

But these things save users from three to ten times what it costs me to give them to you.

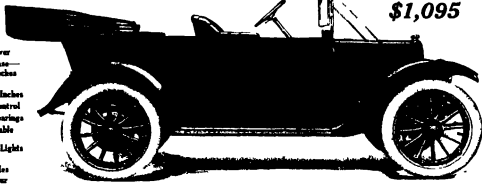

They insure to you safety, economy, comfort. They insure

to me that reputation I have spent 26 years in acquiring.

I find that car users, more and more, are coming to look for this class of car. Our output is always much over sold. And this year, with 60,000 excellent cars to my credit, the demand will be greater than ever.

A thousand dealers are now ready to show this new model of Reo the Fifth. Our 1913 catalog is also ready. Write us for it now.

**Reo the Fifth**  
The 1913 Star  
**\$1,095**

30-35  
Horsepower  
Wheel Base—  
112 inches  
Tires  
34 x 4 inches  
Center Control  
Roller Bearings  
Demountable  
Rims  
3 Electric Lights  
Speed  
45 Miles  
per hour  
Made with 2  
and 3 Panam-  
per Bodies

Tires and windshield not included in price. We equip this car with mohair top, side curtains and slip cover, windshield gas tank for headlights, speedometer, self-starter, extra rim and brackets—all for \$100 extra (list price \$170).

Illustrations are always gladly accepted for examination. Illustrations on subjects of timely interest. If the photographs are useful, the articles and the facts contained in the contributions will receive special attention. Accepted articles will be paid for at regular rates.

The purpose of this journal is to record accurately, simply and interestingly, the world's progress in scientific knowledge and industrial achievement.

## Comparing the Incomparable

IN the early years of the motor truck the relative efficiency of electric and gasoline driven vehicles formed a constant topic of discussion. Today, such pertinacity has practically ceased for it is generally realized that each type has its own distinct sphere of service and it is useless to pit one against the other when they do not run parallel courses. Even slightly speaking the electric truck is in the sphere of small radius while the gasoline truck is presently adapted for long hauls. There are exceptions to this classification of course under certain conditions the gasoline truck can be used to advantage in a small territory and conversely the electric truck can be made with electric trucks. But as a rule, large users of motor vehicles find it necessary and economical to use both the gasoline and the electric types.

In the present issue of the SCIENTIFIC AMERICAN two motor truck comparisons are published, based on data from different sources, and this appears to be rather discrepant. One confines itself to comparing the motor truck with the horse while the other goes a step further and compares the gasoline with the electric wagon. If one uses the question of cost as the points of contact. The comparison is based on an exceedingly large number of observations made by the Massachusetts Institute of Technology. These observations have been carefully tabulated and it was found that the only common factor in the cost per mile of operation. The estimate of expenses has been very thoroughly summed up. It is distributed under four main heads, namely, the energy source, maintenance, repairs, and depreciation. The first two are the most important. The difficulty of making their estimate. It was hard to judge the depreciation of a machine in the limited time during which the observations were taken. This could not be based on the work of old machines. The motor truck is still undergoing development and its maintenance has improved and no doubt new machines, although they have not yet shown their work are long lived than the older ones. Despite these difficulties the Institute has made comparisons which we here present in a summary form on page 70. The result is startling indeed. It is remarkable that the horse is not so hopelessly outclassed, particularly for light delivery as we had been led to believe by previous comparison. For half-ton parcel delivery wagons, the horse-drawn vehicle costs only two cents per mile more than the electric and it is actually two cents per mile cheaper than the gasoline vehicle. Even with the two-ton vehicle he holds his own, and it is not until it has passed the four-ton mark that the motor truck begins to show its superiority.

As we proceed toward heavier vehicles, it is seen that the gasoline truck is gradually creeping up on the electric truck and leaving the horse drawn truck behind. In fact it looks as if the gasoline truck would cross the electric curve somewhere between the six and seven-ton mark.

One important factor we have so far overlooked, namely the extent of territory covered by the various types of trucks. This is a most important consideration. The Institute is in the habit of dividing territory in each case, is assumed to be within four miles of the loading point. That at once explains the poor showing of the gasoline truck. The gasoline truck has been taken out of the element to compare it with the other two types. It is not like comparing a Marathon runner with sprinters over a one hundred yard dash.

## In Defense of Brain Property

IN the hearings before the Committee on Patents, the board brought the views of inventors and manufacturers on the Oldfield Bill, which seeks among other things to compel a patentee to grant licenses under certain conditions, the fact that the American patent system, since its foundation, has given to the public—as distinguished from the patent owner—greater advantages in profiting from inventions than the public has ever had or ever seriously demanded has been completely overlooked. That the benighted constitution makes the inventor and his family the sole beneficiaries of his invention, and that such a system could not have been tolerated in the United States, is hardly to be wondered at. It is a statement which has caused to read the Constitution should entirely mislead. Labor agitators are loudly demanding that the laborer should own the thing he produces. That is exactly what the Constitution granted to the inventor, for the inventor is actually allowed to own for limited periods the thing that he created. Why then should we not sing the single successful socialist property institution in our Government?

The full significance of the reactionary measure that Mr. Oldfield has introduced is to see enacted into law, can be appreciated if we translate the terms of his bill into another language, as it were. If Congress should not only determine that if anyone permits his real estate to go unimproved his houses to remain unoccupied, his land to lie barren, or to be used for anything more than three or four years, then anyone else in the United States may hail him into Federal Court, and by legal proceedings obtain the unconditional permission to build on that real estate, to occupy the land, to use the houses, or to use the land for anything simply upon paying to the unfortunate owner a sum which the court, after some guessing, deems just, we would have almost an exact parallel to the doctrine that Mr. Oldfield seeks to enact upon our patent system.

The purpose of the patent laws of the United States seems to have been ignored. What does the public demand? Simply disclosure of the invention and the right to enjoy it unobstructed after the lapse of a certain period. If the limited monopoly that the inventor now receives is curtailed in the manner proposed, we may expect to find manufacturers refusing to take out patents and endeavoring to keep their processes secret.

Indeed even the present patent system is not quite liberal enough for some inventors. Dr. Buckeland testifies before the committee that a well known photographic paper that he once manufactured is still made in the United States, and Mr. H. W. Leonard, a distinguished electrical engineer and inventor, stated that certain enameling processes of his were not patented, but were carried out in secret. The inventions of both men are valuable, yet it is doubtful if the public will ever know them in the manner they deserve. By the present patent laws, Sir Henry Bessemer, in his fascinating autobiography tells us that he invented a process for making bronze and gold powders, which process he kept secret, we believe, for a number of years. Out of that secret process he made the fortune which afterward enabled him to engage in the costly experiments that eventually gave the world Bessemer steel. If the English patent laws had been somewhat more liberally framed, Bessemer would not have been able to keep the secret of his process, which unquestionably benefited the public of a great right.

## The Block Signal and Control Board

IN view of the present widespread public interest in the subject of safe railroad travel, we direct attention to the fourth annual report of the Block Signal and Train Control Board, a document which should be in the hands of every one who is giving or about to give practical attention to this matter. Copies can be obtained either gratuitously or at a very small price on application to the Superintendent of Public Investments at Washington. The report not only gives a résumé of what has been done in the past, but it also contains suggestions for the future. It is a most interesting and compelling the railroads to install safety appliances, but (and this is perhaps even more important and illuminating) it outlines the proper attitude of the Government in the matter of compulsory legislation, and sound a timely note of warning as to the inadvisability of hasty legislation, that is to say, of legislation which runs ahead of the actual state of the art, particularly as regards the question of automatic train control.

Let it not be supposed from what we have said above that the claim of the railroad officials made at the recent investigation of the Westport disaster in this city that there was no practicable train stop in existence, is maintained by the Institute. For several years past the Board has been carrying on exhaustive tests on

automatic stops which in its judgment gave promise of being of practical value. Speaking of these tests, the report says: "The information obtained from tests, together with knowledge of the general state of development of the subject, has led the committee of the Board to conclude that there are several types of apparatus and methods of application which, if put into use by the railroads, would quickly develop to a degree of efficiency adequate to meet all reasonable demands." Yet the Board is perfectly fair in the railway for it says that it does not wish to be understood that the conditions of entirely acceptable automatic train control as formulated by it in the ten characteristics published in its report (see page 67 of this issue) are fully met by any one of the devices that has thus far examined. In the opinion of the Board the art of automatic train control is "still largely in the experimental stage," but it considers that it is far enough advanced to warrant the installation of available devices with a view to their further development to meet the demand for safety in train operation.

It is well understood by those of us who keep in touch with railroad matters that, hitherto, the railroads have not only failed to show any disposition to encourage the invention and development of the automatic stop, but that they have been, in most cases, strongly averse to it. This opposition certainly cannot be due to a belief that the production of a satisfactory device of the character of the mechanically impossible for the mechanical or electrical elements involved are not materially different from those used by the railroads in the every-day operation of their interlocking and block signals, train brakes, and other devices. The average railroad management is desirous of getting the largest amount of service possible out of its lines in the shortest possible time and, incidentally, of doing this with the least amount of risk either to rolling stock or to passengers and employees. But unfortunately there is a tendency to slight the real consideration in favor of the first. Certainly the cry of "the first" has not been to the ruling principle in railroad operation and the Board is perfectly justified in its opinion that the question of the actual design and construction of the automatic stop for a specific train control system has not been as great an obstacle in the way of the adoption as the operating question involved in its use.

The independent inventor working alone of the railroads has done his best in the past in producing several promising designs for automatic train control on steam railroads. The automatic stop has been proven to be a thoroughly practical device under the exceptionally dense traffic of the New York subway, where it has been in use for many years. It has even reduced the number of trains that can be run in a given length of track in a given time with safety. The Block Signal and Train Control Board has shown, by test, that there are stops suitable for steam railroads which are in the line of the most advanced developed by the railroads themselves, would soon be brought to a point at which they would satisfy all requirements of daily operation. Furthermore there is just now great activity, expert and otherwise, being shown in this field, and undoubtedly additional devices will be forthcoming for use by the Train Control Board.

It is evident that the question has reached the point where it is distinctly up to the railroads, and upon their action alone, will depend the future of the compulsory legislation by the Federal Government. It is certain that the railroads do not want compulsory legislation, and it is equally certain that they can prevent it only by a change of attitude and a sincere and hearty co-operation in meeting the increasing demand of the traveling public. The Board does not believe that at the present time legislative compulsion would be wise, but it does believe that the railroads should be urged and expected to develop the art of automatic train control, so as to provide devices which will meet their operating conditions. "This," says the report, "appears to the Board to be entirely practicable, and should not be done with a reasonable degree of expedition, steps should be taken by the railroads to effectuate such action."

The case could not be more fairly stated, let us hope that this may prove to be that word to the wise which is sufficient.

Agriculture in the Congo.—Since the Belgian government has been carrying out active operations in the Congo region, the interest in the agricultural work which is being carried on there, and especially the attractive botanical garden and establishment located at Kala where observations are made upon native plants, has been increased. The area now in use is about 800 acres, of which, some 500 are devoted to the general garden proper. The personnel consists of 5 specialists including an entomologist and a chemist, with 500 natives engaged on the premises. An annual fund of \$30,000 is allowed.

## Engineering

**Installing Railway Bridge Gates.**—Several of the fourteen sluice gates required in the Gates project have been put in position. These gates are massive structures of steel, 19 feet high, by 47 feet 10½ inches in length, each weighing 44 tons. They will slide vertically in steel grooves formed in the concrete piers which have been built above the crest of the spillway dam, and they will serve to regulate the height of Gates in Lake Umbagog.

**New York Reverts Twelve Thousand Buildings.**—During the past year some twelve thousand structures of various kinds were erected in New York. They were all dwellings for single families, the sum of \$207,000,000 expended would furnish sufficient homes for a city of 100,000 people. In Manhattan alone, the cost of \$116,000,000 was lavished in the construction of buildings. During the year, over \$30,000,000 was expended on office buildings alone.

**Diessel Marine Engines of 24,000 Horse-power.**—It is authoritatively stated that the German navy is having constructed a twin-screw Diesel marine engine, which will consist of two sets of six-cylinder, double-acting engines, each set giving 12,000 horse-power, or 2,400 horse-power per cylinder. To those who have closely followed developments, this information will cause no surprise, for the Germans have been making wonderful strides in the construction of oil engines of large size.

**New Gyroscopic Compass a Success.**—A board of naval officers appointed to test the new gyroscopic compass, which was installed experimentally on the destroyer "Worden," have found it to be remarkably free from oscillation due to the rolling and pitching of the vessel. Experiments which have been made with the same compass aboard a submarine show that it enables a helmsman to steer a more accurate course when the vessel is submerged.

**Turkey Sells Her Dreadnoughts.**—All work has been stopped by Vickers, Ltd., of Barrow, on the construction of the Turkish dreadnought "Mehmed Resad V." The vessel will probably be completed for some other power. A sister ship under construction by Armstrong will also find its way to some other navy. The Turkish cruiser "Drama," of 2,400 tons, built at Italy for \$1,000,000. There is no difficulty, in these days of feverish naval activity, in finding a ready market for warships.

**A 10,000 Horse-power Transmission Gear.**—A test has recently been made at the Vulcan Works, Hamburg, of a 10,000-horse-power hydraulic transmission gear, of capacity of 10,000 horse-power. This is one of two transmission gears which are to be fitted on a new German liner. The plant underwent a continuous trial of two weeks' duration, night and day, under high load. The turbine shaft is designed to revolve 800 revolutions per minute and the secondary or propeller shaft at 170 revolutions. The transmitter ran smoothly without noise or vibration, reversing took place rapidly, and the efficiency obtained was close upon 90 per cent.

**A Sun-power Plant in Egypt.**—At Siwa, a suburb of Cairo, is a sun-power plant of unusual interest. It consists of five radiators, each 204 feet long, whose cross-section is in the form of a parabola, with the generator units as the focus. The last-named are of steel, built of rectangular sections 14 inches wide. To render them efficient, they are painted with a black paint of high heat-absorbing capacity. The water is introduced at the lower end and the generator at its upper end and is provided with a steam connection 4 inches in diameter. The radiators are lined with silvered glass mirrors. The plant works best at a pressure slightly below the atmosphere.

**The New Quebec Bridge.**—The revised design for the Quebec bridge is so far advanced that details of the principal members are available. The main span is 1,800 feet long. The two towers are 1,000 feet apart. The bottom will consist of double lines of 18-inch steel. The bottom chords will have the enormous dimensions of 7 feet height by 10 feet width. The length from panel point to panel point will be 96 feet, each full panel of the bottom chord for one truss will weigh 200 tons. Each end tower has for the tower top web 500 tons. The struts reaching from panel point to panel point are massive plate girders 10 feet in depth, each weighing about 60 tons.

**The Essential Features of the Diessel Engine.**—In the course of a paper recently read by him at Berlin, Dr. Diessel denied that the essential feature of the Diessel process was the auto-ignition of the fuel. He stated that process in which the auto-ignition of the fuel took place was in use before the Diessel process came into being, but that he had never used the term "auto-ignition" in any of his papers. What he was alluding to was a process in which heat was utilized to the highest possible extent, and auto-ignition became embodied in the process last mentioned during its evolution, of the engine. "The history of auto-ignition of the fuel," he said, "is not indicated by the ignition limits of the fuel, but merely by the structure, by which the highest possible limits for auto-ignition are obtained."

## Electricity

**Wireless Telegraph Station at the Vatican.**—It is stated that a private wireless telegraph post is to be installed in the Vatican which will transmit to a considerable distance, and the Vatican telegraph company has already furnished the first part of the apparatus. The antenna will be set up in the gardens of the Vatican.

**Rathenau Medal Awarded to Edison.**—On the evening of January 28th at the American Museum of Safety, the Rathenau medal for the best electrical process or device for safeguarding life and health will be awarded to Thomas A. Edison. He will be the first American to obtain the prize. It will be presented to him because of his storage battery, which provides a safe power supply for use in mines, submarine boats, and factories where explosive vapors made.

**Increase in the Use of Wireless Telegraphy.**—The annual report of the British Postmaster-General states that wireless telegraph messages sent to and from ships have increased 11.8 per cent. beyond the previous year. The increase is partly due to the larger number of vessels now equipped with "wireless" and partly to a reduction of tariff for vessels making short voyages. Nearly all of the wireless stations in Great Britain are now in the hands of the Post Office, the only private commercial stations being the Marconi stations at Clifden and Poldhu.

**Twenty-seven Year Progress in Incandescent Lighting.**—A French electrical magazine publishes an interesting diagram showing the progressive reductions in the cost of the incandescent electric light which have taken place since 1885. The improvement has been twofold in the increasing efficiency and life of the lamp and in the reduction in the cost of current. It is a pity that it is not realized by the average consumer of electricity that whereas the first carbon filament lamp, supplied with energy at about 25 cents per unit and consuming 5 watts per (British) candle-power, gave only 200 candle-power for 25 cents, with the best type of draw-wire tungsten filament lamp today, supplied with energy at 8 cents per unit and consuming 1¼ watts per candle-power, the same sum of money gives 2,400 candle-power.

**Replacing Reel-coating Engine-driven Generators by Turbine Units in England.**—In one of the generating stations of London it is proposed to "scrap" engines and generators of about ten years' age, and of 10,000 kilowatt aggregate capacity, because the present output of the station is insufficient to meet the demands of the tramways supplied from the station. By replacing four repeating engines, each of 1,500 kilowatt capacity, with four 4,000-kilowatt steam turbine-generators, the maximum output will be largely increased. Two of the old sets will be changed at a time and it is estimated that the saving in coal will be over \$57,000 for the first two turbines, which more than offsets the debt charges incurred by the change.

**A New Direct-current Steam Turbine-generator.**—The generation of direct-current electrical energy by the steam turbine-generator has been a problem on account of commutator difficulties at the high rotating speed at which steam turbines should run in order to show a steam economy comparing favorably with the re-arranging engine. In the effort to solve this problem so-called "unipolar" steam turbine-generators having a highly simplified current-collecting device, and reduction gearing between the steam turbine shaft and the electric generator shaft, have been tried. A new scheme for direct-current generation is now announced in the form of an alternating-current induction generator combined in one machine with a rotary converter. In this turbine converter, one member of the generator is mechanically the converter shaft and the other member (usually a squirrel-cage rotor) on the turbine shaft with the revolving field of the generator arranged to rotate the same way as the converter armature, giving a net generator speed equal to the converter speed. In a set of 500 to 800 kilowatts capacity the full-load efficiency is stated to be 94 per cent.

**Magnifying Feeble Signaling Currents.**—Two interesting types of relay for submarine cable work, designed to improve on the "siphon recorder" invented by Lord Kelvin in 1867, were demonstrated at the Electrician's exhibition in London. The problem of high speed working is to cause very feeble transient currents to make distinct records. In one of the new devices the object is attained by mechanical means. The suspended coil of the relay has two thin members, one of which is a rotating spindle. The slight movement of the coil either direction, by slightly increasing the friction of one or the other of the fibers on the rotating spindle, causes the latter to supply a supplementary force many times greater than that exerted by the coil by turning on a device which virtually magnifies the feeble arriving current by thermo-electric means. The suspended coil carries an arm at the end of which are two tiny thermo-electric couples forming a T between two little alloy flames. The slight movement of the coil, by turning on a switch, causes the thermo couples toward one flame and away from the other, generates a current in the one direction or the other 27 times greater than the received current.

## Science

**A Swiss National Park.**—A magnificent national park, the largest in Europe, is about to be established in the canton of Graubünden, Switzerland. It will ultimately have an area of nearly 80 square miles, all of which will be wholly within national interference and set aside as a biological preserve.

**Changes in the Map of Greenland.**—A series of maps prepared by the results of the surveys carried out by the ill-starred Mylius Eriksen expedition of 1906-08 to northeastern Greenland has been published in the *Geograph. Tidsskrift*. These show that Greenland extends much farther east than was formerly supposed, and adds about 150,000 square miles to its area.

**Amundsen's Proposed North Polar Journey** has been postponed for a year, at the suggestion of the Norwegian government, according to Prof. Nansen, in order to give the staff more time for thorough training in oceanography, the subject to which the expedition will devote principal attention. Captain Amundsen is to be promoted with a gold medal for his discovery of the South Pole, at the annual banquet of the National Geographic Society, in Washington January 11th.

**A Privately Requested to Science.**—The will of Albrecht Rammson, who died recently in Brussels, bequeathed the bulk of a large estate for scientific research. Two endowments are created, one under the control of the Royal Prussian Academy of Sciences, the other of the Royal Academy of Sciences at Munich. The Prussian endowment is worth \$500,000, the Bavarian \$100,000. The Berlin endowment is to carry out scientific researches into individual as well as social themes. The endowment for the Munich Academy has a similar purpose.

**French Expedition to Morocco.**—The Geographical Society of Paris, added by the French Academy of Sciences, the National Museum of Natural History and a number of banking institutions, has organized an expedition which will carry on elaborate scientific explorations in Morocco for four or five years, and perhaps longer. The party is made up of well-known specialists in several fields, including M. Gentil who will have charge of geology and mineralogy, M. Haugue in charge of agronomy, M. Ballay, zoology, and Prof. Pridat, botany.

**An Institute to Study Fleas.**—Under the auspices of the Kaiser Wilhelm Scientific Society there has been founded an institute for research upon embolism. The institute, which is situated at Berlin, has a capital of \$100,000, and the State alone annual endowment of \$30,000. Another endowment comes from the mining syndicate of Westphalia and the Rhine amounts to \$25,000, and the above-mentioned society itself contributed the sum of \$5,000. It is stated that the buildings of the institution will be opened for use early in 1914 and the director is to be Prof. F. Faucher, of the Berlin Hochschule.

**Changes in the Weather Bureau.** The River and Flood Division of the Weather Bureau, which has charge of the important work of stream-gauging and river-gage prediction, has been placed under the direction of Prof. A. J. Henry, lately in charge of the Mount Weather Observatory. He is succeeded at the latter institution by Dr. W. R. Hale. Former officials of the Bureau have recently promoted to the grade of professor of meteorology, viz., Dr. O. L. Pung, the well-known climatologist, now in charge of the station at Baltimore, J. Warren Smith, a specialist in agricultural meteorology, who is stationed at Columbus, O., and W. M. Wilson, stationed at Washington, D. C. The latter is in charge of the library and supervising examiner of the Bureau and W. R. Blair, of the Mount Weather Observatory, have been appointed junior professors, a new grade in the service.

**The Sphygmomanometer** is an instrument of recent invention for measuring the blood pressure. The name is derived from *sphagma*, the pulse, *man*, thin, *meter*, and *manometer*. The manometer has been in use for some time as an instrument for measuring the tension of gases and vapors, and was readily adapted to testing blood pressure by adding a rubber bulb with a small rubber bag attached on the inside. This is placed over the brachial artery, above the elbow, and when the pressure through the rubber bulb has shut off the artery so the pulse cannot be felt at the wrist, the reading in the graduated scale gives the systolic pressure in mm. Hg. indicates the blood pressure. The normal blood pressure is 126 millimeters. In hardening of the arteries, and accompanying heart and kidney complications, the blood pressure is an important symptom. The measurement of the blood pressure requires the use of a sphygmomanometer. The blood pressure is taken in applications for large amounts. One company requires it in all applicants without regard to age or amount. This company claims they require \$50,000 to \$100,000 of the systolic pressure which is the normal blood pressure. They followed the history of cases registered on account of high blood pressure only, and found several who died within the year of asphyxia.

## Moving and Talking Pictures

**M**OTION pictures are at the present time usually exhibited by optical projection, enlarged images of pictures carried by a long strip of film being thrown upon a screen or curtain. This process is to a large extent the reverse of that employed in taking the pictures, to effect which reduced images of the scene which is to be reproduced are allowed to fall in succession upon a sensitized film. In the apparatus commonly employed for obtaining the pictures snap-shots are taken at the rate of sixteen per second upon the film which is intermittently moved. A rotating shutter provided with an opening allows successive images per second to fall in succession upon the film. The strip is so constructed that the film is held stationary while each picture is taken and then is moved forward at a high rate of speed into proper position for the next picture, this movement occurring at the time when the shutter is so positioned as to protect the film from the light. The film carrying the exposures is developed, and from the negatives thus obtained prints are made upon a similar strip of film for use in the projection apparatus. This apparatus is usually similar to the camera except that a powerful light is provided to throw successive images of the pictures upon a screen. These images are enlarged by means of an objective lens, and appear upon the screen with such rapid succession that before one picture has time to fade from the retina of the eye another one is in view. Since each picture is slightly different from the preceding one and since the pictures blend imperceptibly into each other, the illusion of movement is produced, and the observer sees the original scene re-enacted.

On August 24th, 1897, Thomas A. Edison filed two applications for patents, one of which became patent number 403,426, dated March 14th, 1893, and, therefore, expired on March 14th, 1910. The apparatus disclosed in this patent involves a cabinet having a slight opening in which the picture film is continuously moved, each picture being momentarily illuminated when it is accurately centered with relation to the slight opening. This device is not adapted to project pictures and provides for only one observer at a time. A device of this character was for a time in extensive use, but it has now been largely replaced by the projector. The other application referred to matured into patent number 500,108 on August 31st, 1897, and consequently does not, or rather the releases which have superseded it do not expire until August 31st, 1914. The device covered by this patent is intended only for taking pictures, but it, however, illustrative to a large extent of the principle both of the camera and the projector commonly used. The apparatus is shown in Figs. 1 and 2. The film 3 passes the lens tube on its way from the reel 1 to the reel 2, being drawn along by two feed wheels 6, the teeth of which engage perforations placed along each side of the film. The film would move continuously were it not that the rotation of the feed wheels is periodically checked by the interaction of the toothed wheels, the one 25 mounted on the main shaft 20 and the other 23 on the feed wheel shaft 6. One tooth of the wheel 23 is allowed to engage at a time, and thus the film is intermittently advanced. Mounted on the shaft 20 to rotate between the film and the lens tube is a disk 11, which is apertured to permit the light rays to fall upon the film each time the latter stops.

Although present in a different form from this machine yet certain features have been used in various machines. This patent has, therefore, been used as the basis for litigation. The Court of Appeals of the Second Circuit (114 F. 2d, 1020) held claims 1, 2, 3 and 5 of this patent invalid on account of being broader than the state of the art warranted. Claim 1 covered the combination of three elements (1) any means capable of intermittently projecting at such rapid rate as to result in persistence of vision images of successive positions of the object or objects in motion as observed from a fixed and single point of view, (2) a sensitized tape-like film, (3) any means for so mov-

ing the film as to cause the successive images to be received thereon separately and in single line succession. The scope of the second claim was the same except that it was limited to a single camera with a single lens. The third claim differed from the second only in that it was restricted to intermittent motion of the film and exposure of the film during the periods of rest. The court based their decision on the following four references. The French patent to Ducos of 1864 describes a camera having a large number of lenses caused to act in rapid succession upon a series of sensitized plates or a surface of sensitized paper. The lenses and the sensitized surface move continuously at the same rate of speed while the picture is taken, one lens after another passing an aperture which admits light. The images are formed from the same point of view—the single aperture. U. S. patent to Le Prince, 870,247, January 10th, 1888, discloses a camera provided with a battery of sixteen lenses which act upon two strips of sensitized film placed side by side. The lenses are provided with shutters, eight of which facing one film are operated in rapid succession. The eight facing the other film are then operated, during which time the first film is moved into position to receive another eight exposures and so on. Unlike the Ducos camera, the lenses in this device are fixed and, therefore, the pictures are not all taken from the same point of view. The photographic gun of M. Marey, described in the *REVUE DES ANNALES D'OPTIQUE* of June 1904, 1895, discloses a single lens camera which takes twelve pictures in a circular series around a sensitized plate rotated behind a slit which allows entrance of light. The plate is rotated intermittently by clock work arranged to give one rotation with twelve periods of rest. The number of exposures for one operation is limited to twelve. Mr. Levinson in the *BROOKINGS* of June 14th, 1894, described a camera for taking motion pictures in which a single lens is employed to obtain images on plates carried by an intermittently operated wheel, each plate being exposed while at rest. He stated further that the mechanism employed to drive the plate carried could be employed to operate a continuous strip of paper or a film carrier. The court held that in view of these references the invention of Mr. Edison was not in such case a primary one as to authorize the claims on which suit was brought. In regard to the prior art they stated in particular that he was anticipated by Marey in an apparatus capable of producing negative and embodying means for painting a sensitized surface across a single lens camera at a high rate of speed and with intermittent motion and for exposing successive portions of the surface during periods of rest. The fifth claim of the patent, which was for a film having the photographs thereon was also held invalid in view of the references. Claim four of the patent was not included in the suit and was not passed upon by the court in this decision.

After the patent had been adversely passed upon it was renewed in two parts. Release No. 14,687 for the camera and release No. 12,038 for the film. The releases for the camera contained four claims, the first three being more limited than those in the original, while claim 4 was the same as claim 4 of the original. Claim 1 contained four elements: (1) a single stationary lens, (2) a single sensitized tape-like film supported on opposite sides of and longitudinally movable with respect to the lens, and having an intermediate section crossed by the lens, (3) feeding devices engaging such intermediate section of the film and moving the same across the lens of the camera at a high rate of speed and with an intermittent motion, (4) a shutter exposing successive portions of the film during the periods of rest. Claim 2 also included a continuously rotating driving shaft, by which the feeding devices and the shutter were operated. It limited the shutter to a continuously rotating shutter. Claim 3 differed from claim 2 in causing reference to the shutter as being continuously rotating and operated by the shaft, and included a reel for winding

(Continued on page 74.)

# A Successful Automatic Train-stop

A Device Which Saves the Train, Reports Disregard of Signals, and Thereby Stiffens Discipline

IN the fourth annual report of the Block Signal and Train Control Board to the Interstate Commerce Commission in December, 1911, there occurs this paragraph: "The Board has no hesitancy in saying that had the railroads directed the same efforts toward the development of automatic train-control apparatus that has been devoted to the development of interlocking and block-signalling apparatus, we should now have adequate devices, which would permit an engineer to handle his train without interference as long as he did it properly, but would intervene to stop his train if he disregarded a stop signal or ran at excessive speed, where speed restrictions were prescribed."

During the past fifteen years the *SCIENTIFIC AMERICAN* has repeatedly drawn attention to the growing number of fatalities and injuries on our railroads, and for many years we have urged the use of the automatic train stop as a salutary check upon disobedience of signals and a most effective safeguard of the lives of passengers. Unfortunately, the railroad companies, for various reasons, have been opposed to the train stop, and with a few exceptions it is only recently that they have begun to give it unwilling attention. A few roads, operating under special conditions, have installed the stop, and in such cases, particularly on the New York subway, it has proved to be a brilliant success. To-day some roads are testing out devices of this kind that have been developed on the outside, and one rail road has recently made the offer of a reward, the conditions of which will be found on the correspondence page of this issue in which it solicits the assistance of the outside public in the solution of the problem.

The success of the mechanical trip train stop, as used on the New York subway where, during several years of operation on express trains under a headway of one minute and 43 seconds, there has been only one failure out of 277,848 movements, proves that, when it is installed in subways or under conditions such as those on the Boston elevated road, where it is not subject to attack by snow and ice, this type of stop is thoroughly reliable.

For use in the open on steam railroads, however, where the mechanism both at the rail and on the train will be subject to destruction or disarrangement by snow and ice, or by trespassers on the tracks or intentional train wreckers, the problem is more difficult and modifications become necessary. In all probability it will be found that the most satisfactory system is one which operates electrically upon what is known as the "closed circuit" system, and disposes altogether with projecting mechanical parts which are liable to be injured or entirely carried away in the stress of day-by-day railroad operation. Also, it may be taken for granted

In block 2, which is clear track battery  $b$  through circuit  $b-c-d-f$  relay  $r$  contact  $g$  and signal battery  $h$ , causes magnet  $h$  to lower semaphore  $l$ . In block 1, main axle  $y$  short-circuits track-current  $i$  is released and relay  $r$  is caused to return to stop position.

Relation of automatic signal and stop to train brakes.

Home and distant signals clear, stop lowered.

that the successful, electrically-operated device must form part of or co-act with the track circuitry which operates the standard block signals as installed on our railroads.

It is necessary that anyone who undertakes to solve this problem should have a clear understanding of the operation of the electrically-controlled automatic block signal system. To this end we have prepared the accompanying diagrammatic view showing its basic features, which consists of a track battery  $a$  furnishing a low voltage electric current through wire  $b$  to one line of track rails  $c$  at the end of a block  $Z$ , which is limited by means of insulated joints from the adjoining block, a wire connection  $d$  to a relay  $r$ , which is energized by the current as thus supplied and the other line of track rails  $f$  closing the return circuit to track battery  $a$ . The relay being thus energized, attracts the armature  $i$  and makes the contact  $g$ . This permits current to flow from a signal battery or other source of power  $h$  to the signal magnet or motor  $l$ , which holds down the semaphore  $m$  against the action of the counterbalance  $n$ , which normally holds the semaphore in the horizontal or stop position. A train  $v$  approaching block  $Z$  observes that the semaphore is in the downwardly inclined position and has the right to proceed into the block  $Z$ .

If a train  $v$  occupies block  $Z$ , the front axle of the train short-circuits the track current, the relay is de-energized, and it no longer holds the armature against the contact. The reason the signal magnet or motor, as the case may be, is deprived of current and the counterbalance weight  $n$  automatically draws the semaphore into the horizontal or stop position warning the approaching train that the block is occupied. A broken rail interrupting the flow of current in the track circuit or any defect in the apparatus that breaks the circuit, de-energized the signal magnet or motor  $l$  and allows the semaphore to go to the stop position.

This method of controlling the signal is known as the "closed circuit" principle. It is essential to the safe operation of a system which must rely on the side of safety should anything go wrong. For successful automatic stop must be arranged on this same closed-circuit principle, it must be included in the circuitry which controls the block signals, its means to clear or stop must be co-ordinated with those of the signals, and any failure of the circuits or mechanism must cause it to be driven by gravity to the stop or danger position.

Now the same broad principle is followed in the automatic airbrake (see diagram). The main reservoir  $A$  on the engine, the train pipe  $C$ , which runs the full length of the train, the auxiliary air reservoirs  $F$  on each car are normally maintained under full air pressure. When the engineer closes the brake valve  $B$  the pressure in the train pipe  $C$  and branch

Stop rail with valve on pipe and stop broken.

Counterweight in box raises stop when signal is at danger.

AUTOMATIC SIGNALS AND STOP AS USED IN NEW YORK SUBWAY.

pipe *D* is reduced, and this causes the triple valve *N* to admit air from the reservoir *R* to the brake cylinder *C*. Each car, thereby setting the brakes. Any failure of the air pressure, as in case of a train breaking in two causes the brakes to be automatically set. For automatic stop setting of the brake, a trip branch pipe *F* is led down from the train pipe and terminates in a triple valve *J* provided with a trip lever *L*, which is so placed that it will engage with a trip *L*, when the latter is in the raised or stop position.

The mechanical trip as installed in the New York subway, and elsewhere is shown in the diagram and in the three photographic views. It consists of a short lever placed adjacent to the track rail, which is normally held down clear of the trip valve lever *K* by the compressed air piston *M*. The valve admitting compressed air to the back of this piston and to the piston operating the signal *S* is controlled by electro-magnets in the signal circuit, as described above. Normally, the trip, like the signal, is maintained in the clear position but when the block is occupied, the air pressure back of *M* is released and the trip rises to the stop position under the action of the counterweight *Q*.

Now it is evident that the work point, if there is one, in this system is the possibility of a failure of the trip to register with the trip valve lever, either through one or the other being broken entirely off or twisted, or through their movements being obstructed, as in the New York subway, or by the possibility of a possibility is very remote but in the open on steam rail roads, especially during the winter months, it might well happen. If there were such disarrangement, the engineer would be unaware of it. Heretofore this considerable peril, and it is for this reason, among others, that railroads operating in the open have been opposed to the mechanical stop. To quote one of the leading railroad engineers in the country "If an automatic stop is to be generally employed on American railroads, it must be certain in its action and the means that it must be constructed on the closed-circuit principle, a failure in the co-ordination in the parts of which must be just as certain to stop the train as a fractured rail or a defect in the apparatus will bring about a stop indication of the signal apparatus."

In the presence of this dilemma, the thoughts of inventors have naturally turned to electricity and the substitution of electrical contacts for mechanical stops. One system the Icarus, using a third rail contact and an electric circuit, result in the fact that the question of a series of tests by the Block Signal and Train Control Board, received the following endorsement "The test indicated that the apparatus could be expected to operate satisfactorily under severe weather conditions. The system with reasonable inspection and maintenance would be safe, reliable, and its use would tend materially to promote safety of operation on a railroad today." We quote this case to show how entirely without justification is the contention of the steam railroads that there is no automatic stop in existence or in sight, that it will meet the severe requirements of daily out of doors operation.

Admitting as essential to a successful stop the principle that the whole apparatus-track circuit, electric circuit and the contact connections between the two must be upon the closed-circuit principle, detecting its own failure and incapable of giving a false "clear signal," this problem becomes a most interesting and attractive one, capable of a wide range of variation in its solution. The automatic train stop has come to stay. Its necessity is becoming evident, and it is to be hoped that the railroads generally will change from an obstructive to a favorable attitude, and that the train stop will be adopted voluntarily and widely and without any resort to Federal legislation.

### The Death of Dr. Lewis Swift

ON January 8th Dr. Lewis Swift, one of the great astronomical observers of our time, died at Marat (near V.) at the ripe age of ninety two. He was chiefly noted for his work on nebulae, of which he discovered more than his studies of comets. In the year 1869 he made investigations of shooting stars, solar eclipses and possible interplanetary planets. It is said that his first interest in astronomy was aroused by reading Dr. Dick's books at a time when he was in business. He made his reputation with his discovery of the comet that bears his name, a discovery that resulted in his removal from Hunt's Corners to Rochester. There, on the roof of a older mill he set up an invaluable observatory where he discovered comet after comet and nebula after nebula. Most of his work was done while he was in business in Rochester.

### Blackening Tan Leather

TO blacken tan leather it should be first rubbed with ten per cent solution of tannic acid. Let this solution dry thoroughly, when a solution of iron sulphate should be applied. This gives an iron black, is easily applied and is harmless to the operator.

### Trains and Motor Trucks Compared

By H. W. Perry

THE front page illustration tells its own story so plainly that it is almost unnecessary to amplify it. Some of the advantages of the motor trucks over the train drawn wagon may be thus summarized: The average distance covered per day by a two-horse team between 15 and 20 miles, whereas the average distance covered per day by a three or five-ton motor truck varies between 40 and 60 miles. Horses and wagons could serve daily an area of 814 square miles on a ten mile radius, on the other hand motor trucks, operating on a 20-mile radius, would cover 1,983 square miles.

The work done by a two-horse team per day varies from 48 to 60 ton miles. On the other hand, motor trucks of from three to five-ton capacity perform an amount of work measured by 165 to 235 ton miles per day.

At \$8.50 per day, the cost per ton-mile of hauling by train is 17.7 to 14.16 cents, but the cost per ton mile of hauling by three or five-ton motor trucks at \$12.25 to \$15.00 per day is 7.42 to 6.58 cents.

Equally remarkable is the amount of space occupied by the horse-drawn truck as compared with the motor truck. A team and wagon is about 20 feet long, a three to five-ton motor truck, 30 feet long, and a four-ton motor truck and wagon is about 30 feet long, and a ten-ton motor truck, its horse-drawn equivalent, only 25 feet long. So far as space are concerned an ordinary team and wagon occupy 132 square feet, but a three to five-ton motor truck only 140 square feet.

In the matter of storage space required for gasoline and feed the motor truck engine displays an advantage. An amount of hay and oats sufficient to feed a motor truck occupies a volume of 120 cubic feet, but the gasoline required for a motor truck for one month will occupy only twenty cubic feet. The cost of hauling by motor truck is incomparably cheaper than by horse and wagon. Thus, the cost of hauling 1,000 tons ten miles by horse and wagon is \$160, but only \$70 by motor truck.

The amount of work performed by one motor wagon is equivalent to the amount of work performed by three or four half average teams. To haul 595,000 tons an average distance of one mile in a year would require 100 teams, but 39 motor trucks would theoretically be required to haul the same load an average distance of one mile in a year.

The cost of keeping and using 39 teams and wagons per year would be \$68,450, but the cost of keeping and using ten motor trucks would be only \$42,000.

Judging by the registration of horse-drawn wagons in Chicago, the use of horse-vehicles is decreasing at the rate of 15.4 per cent per annum. In other words 65,000 horse-drawn wagons were registered in Chicago in May, 1911, and only 55,800 in September, 1912. On the other hand the use of motor trucks is increasing at the rate of 120 per cent a year, this estimate being also based on Chicago statistics. It seems that the number of motor trucks registered in Chicago in May, 1911, was 800, and the number in September, 1912, 2,004.

### Bronchitis

IN this week's SCIENTIFIC AMERICAN SUPPLEMENT Mr. A. C. Pittsburgh Talman gives an account of some curious acoustic phenomena which have been generally called "bronchitis," "metopoeia," or "Barisal guns," but which bear scores of other names in various parts of the world, and are in the form of a low, dull, rumbling, resembling the sound of distant cannon, or peal of thunder, and are heard chiefly in warm, clear weather.

The first systematic investigations of these phenomena were made in India. The fact that they were frequently reported from the neighborhood of Barisal, a town in the Gangetic delta, led to their being called "Barisal guns," under which name they were first made known to European science at the meeting of the British Association in 1860. A few years later they were discussed in an extensive memoir by H. van den Broek, who had collected numerous reports of their occurrence in Belgium, where they are known as "metopoeia" (i. e., "fog-bellings" or "fog-bellings"). The most extensive literature on the subject, however, has come in recent years from Italy, where the sounds appear to be extremely common, though very local in their distributions; they are well known in some localities, but entirely unknown in others not far distant. They are popularly known under a great variety of names in Italy, but since 1864 have been generally called "bruciores" (i. e., "bruciores" in English and French). In Australia the sounds are called "secret songs," in Haiti, "gouttes," etc. They have been reported from some parts of the United States, especially California.

It is difficult to define their distribution, because, except in places where they have been definitely shown, they are likely to pass unobserved—being often by many people for actual discharges of cannon, lightning, explosions, and the like.

When once the attention of the world had been directed to the supposed occurrence of bronchitis it was found that there are numerous references in early literature to apparently the same phenomena. Thus Lord Bacon speaks of "an extraordinary noise in the sky when there is no thunder."

The latest views as to the origin of bronchitis are summed up as follows:

"Many suggested explanations that seemed more or less plausible when the problem was viewed as a local one—as in the early discussion of Barisal guns—are invalidated by the wide range of physical conditions under which the phenomenon is now known to occur. The trend of recent opinion is toward looking upon the source of bronchitis as subterranean in most cases, though perhaps not in all. Movements within the crust of the earth must frequently set up vibrations of such amplitude as to affect the air when circumstances are favorable to the overlying atmosphere. Assuming the focus to be far below the surface, the air would be set in vibration over a wide area, giving the indefiniteness as to the direction of the sound that is commonly noted. Prof. H. H. Woodworth, who made a painstaking study of the seismic geology of Italy, concludes that the broil of that country are due to the slow settlement of overgeable blocks, and the consequent production of vibrations within their marginal zones."

Whether the sound is due to the ground, its audibility appears to depend upon definite acoustic conditions that require further investigation. Alippi believes that in order that the sounds may be heard they must be reinforced by a peculiar configuration of the ground, or by the surface, and he attaches special importance to the effect of the wind, which he suggests acts as resonance boxes in the production of audible bronchitis.

### A New Industrial Process for Manufacturing Oxygen

By Our Berlin Correspondent

DR. G. KARNER, professor at Münster University, has designed a new method for the manufacture of oxygen which is based on the Toudé du Motya process but, thanks to the absence of any antagonistic effects, lends itself to a far better industrial application than any chemical method so far suggested. Karner adds to the alkaline solution of potassium permanganate used in the Toudé du Motya process an alkali salt of metaporphoric acid, thus increasing enormously the efficiency and constancy of the mass. The process comprises two phases characterized by the action of currents of steam and air, respectively. During the first phase the alkali salt off by dissociation is immediately absorbed by the alkali metaporphoric, thus forming orthoporphoric. Inversely, during the second phase, which is that of regeneration, the alkali absorbed by the metaporphoric is given back to the radical manganese oxide, thus forming alkali metaporphoric. This is how the formation and decomposition of the manganese due to the addition of metaporphoric (which eliminates any disturbing antagonistic effects) takes place in continuous succession, without any appreciable alteration in the composition of the mass.

In opposition to physical processes which only utilize indirectly the heat units given off by the fuel, this chemical process works without any appreciable heat losses. It is the following:

After being introduced into a suitable apparatus refractory to heat and insuring a constant temperature, the active mass is, by means of a special fire-place, raised to and kept at the relatively low temperature of reaction, about 450° C. The mass is then subjected to controlled valve causes separate currents of steam (exhaust steam), and air to enter this mass, at short intervals of equal duration. By inserting a very short discharging phase between the air and steam phases, any alkaline salt which may be formed in the pores of the mass is eliminated. The oxygen produced during the steam phase is led automatically into a gasometer set apart for this purpose. Moreover, a recovering apparatus serves to transmit any heat units escaping with the exhaust to the entrance of air and steam entering the apparatus, thus preventing as far as possible any loss of heat. Finally, the process is so designed that the charge can be exchanged readily and easily, without any interruption in service work opening at night. It is to be noted that the process will only happen occasionally. As, in fact, the active mass remains constant in quality as well as quantity, it will at most require little treatment (such as a mechanical cleaning) in order to keep it in the best possible condition. In view of the great simplicity of the process, the nature of the fuel, and the new process would seem to lend itself for metallurgical applications.

# The N. Y., N. H. and Hartford Railway's Automatic-stop Prize

Conditions That Must be Observed in the Competition for the \$10,000 Award

**THE** New York, New Haven and Hartford Railroad Company has offered a reward of ten thousand (\$10,000) dollars to whomever shall invent, perfect, and submit the best automatic device that will safely arrest trains disregarding fixed signals.

The reward will be paid on the order of the Interstate Commerce Commission, the Railroad Commissioners of Massachusetts, and the Public Utilities Commissioners of Connecticut.

## Conditions of Competition.

1. Competitors must submit a typewritten or printed description of their device, describing in full all features wherein the device does or does not conform with the requirements as herein below set forth, in consecutive order.
2. Any device which in the judgment of the Railroad Board of the New Haven Company does not satisfactorily meet the essential requirements, will be rejected and if it is the desire of the competitor to have the device developed further, it will be done at his sole expense.
3. Any device appearing in the judgment of the Railroad Board to have sufficient merit or promise to justify more extended consideration, the Railroad Board will award Competitor by contribution of money or use of tracks, or both, in such measure as deemed reasonable.
4. Any device after meeting the requirements must show an efficiency equal to that of the signal system in use on railroads at the present time before same will be accepted.
5. Any device accepted will remain the property of the Competitor or Patented, subject however to the reserve by the Railroad Company, of a right of use without further payment.
6. Before any device is accepted it must be adopted for general use by either the New York, New Haven & Hartford, the Pennsylvania, or the New York Central Railroads, within the year 1915, 1916, or 1917.
7. The device must also have the approval of the Interstate Commerce Commissioners, the Railroad Commissioners of Massachusetts, and the Public Utilities Commissioners of Connecticut.
8. Those desiring to enter this competition must file their application before July 1st, 1915.

## Requirements of Stopping Device.

CHARACTERISTICS AS FURNISHED BY THE RAILROAD BOARD OF THE INTERSTATE COMMERCE COMMISSION.

1. The apparatus should be so constructed that the removal or failure of any essential part would cause the display of a stop signal, and the application of the train brakes.
- If electric circuits are employed they should be so designed that the occurrence of a break, short, or ground or a failure of the source of energy in any of the circuits, should cause the display of a stop signal and the application of the train brakes.
- The apparatus should be so designed that it may be used on the open railway on bridges, on elevated structures, in tunnels or subways, and where other means of electricity is used as a propelling power.
- The apparatus should be so constructed as to conform to recognized standards of clearance of rolling equipment and structures, so that those portions of the apparatus placed on the roadway will not be subject to damage by rolling stock or engines, or those portions placed in the vehicle be damaged by structures permitted to exist on the roadway, and at the same time all vehicle parts and roadway parts which may have to come into operative relation with each other should be so designed that proper operative relation will be assured under all conditions of speed, weather, wear of tracks or vehicles, operation, and shock.
- The system should operate under all weather conditions which permit the operation of trains.
- The system should be capable of control by ordinary means used for indicating the condition of the block about to be entered, such as electric track circuit.
- The engine apparatus should be so constructed as to prevent the release of the brakes after the application has been made until the train has brought to a stop, or obstruction of other condition which caused the application has been removed.
- The system should be so designed that should operating conditions require it, speed control may be used, that is, provision made for a train to pass an automatic stop in tripping position without the application of the brakes provided the speed is less than a predetermined number of miles per hour.
- The system should be so designed that when a cause for stopping a train exists, a definite and positive stop indication will be shown at every point where a

stop indication would be given or the brakes applied, where adverse or dangerous conditions exist.

The system should provide at least for use under an existing traffic for the continuous display of indication rather than for their intermittent display at certain definite points, as of course is necessary with fixed signals.

The apparatus should be so constructed and installed that it will not constitute a source of danger to train men or other employees, or passengers.

In addition to above, the following additional requirements must be met:

1. The apparatus should be so non-inductive as that its application to a railroad where attracting current electricity is used as a propelling power it will not affect same.
2. The apparatus should be so constructed that it may be used with either absolute or permissive operation, also to cause trains to reduce speed at points where a reduction of speed is deemed advisable for safe operation of trains.
3. The apparatus should be so constructed that it will not be made inoperative by snow, ice, sleet or freezing conditions.
4. The apparatus should be so constructed that two or more engines may be used with our train or a train may be allowed to coast another train without causing the brakes of the leading train to be set, or following engine when passing a signal which indicated proceed when leading train is stopped.
5. The apparatus should be so constructed that the automatic stopping device shall be operative only in the normal condition of the system in connection with signals governing reverse movements.
6. The apparatus should be so constructed with speed control device that a train may pass an automatic stop in stopping position without brakes being applied provided the speed has been reduced to less than a predetermined number of miles per hour.
7. The apparatus should be so constructed that with speed control device applied, brakes can be released by engine or train crew after they have been held by the stopping device provided speed has been reduced to a predetermined number of miles per hour.
8. The apparatus should be so constructed that if found defective proper apparatus can be provided on the ground to insure the successful operation of the automatic stopping device has been applied to the train.

## Rusting of Iron

IN some very interesting experiments by two German chemists, E. Liebreich and F. Hiltner, the cause of rust in cases which have heretofore baffled scientific investigation has been made very clear—as it was shown beyond question that the rust was caused by the paints themselves. They painted polished steel plates, and in order to distinguish them, numbered them with oil paint. The result was that the rusting took place just under the painted numbers—that is, where the "protective" coating was the thickest.

They went further in the matter, and examined iron business signs and the like. As a rule these were made of sheet iron, first painted with a ground color—mostly white, then the lettering was added, usually in black. Removing the coating, it was shown that the rust was most pronounced under the lettering. In fact in most cases it was to be found only there.

This set the inventors to thinking, and they carried out their experiments with several kinds of paint, as follows:

- White lead.
- Zinc white (pure zinc oxide)
- Red lead
- Iron oxide
- White lead and lampblack.
- Zinc white and lampblack.

Iron plates were brightly polished and four plates coated with each one of the above, in different thicknesses of coat, one plate getting but one coat, a second two, a third three, and a fourth four, time for drying being ascertained. Then all the plates were subjected for a whole day to the action of the steam from water boiling in an open vessel (that is, under no pressure above that of the atmosphere).

The paint was then dissolved off to show the condition of the plates.

The result was surprising. Under all the single coatings the iron was not at all rusty; under the double coat, partly attacked, under the triple coat, more strongly, and under the four coats, thoroughly rusted!

Apparently one coat—at least of the above-named paints—is better than none. The explanation of this remarkable result would seem to be that the various rusts in the second coat dissolve and wash off the first one, making it porous, and that the thicker this process is repeated, the more porous the paint becomes. It would also seem to indicate that one thick coat, if allowed to harden, would be better than several thin ones. These things, too, may be worth considering in this particular case, as in the case of the other.

## Reconstruction of the "Olympic"

IT will be remembered that the investigations of the loss of the "Titanic" led to the widely-accepted conclusion that, although the construction of ship was of the highest character as to material and workmanship, she was deficient in underwater protection. It was recommended, both by the Senate Committee which investigated the disaster and by the Board of Inquiry under Lord Mersey, that certain structural changes should be made, chiefly below the waterline, which would render ships of a design similar to the "Titanic" safe, if not against foundering under any conditions, at least against their foundering under a collision as serious as that which sank the great ship. The most important recommendation was that future ships should carry an inner skin, either in the form of plating on the inside of the main frames of the vessel, or in the form of longitudinal watertight bulkheads, built several feet inward, which would form the inner walls of the bunkers and extend throughout the boiler spaces.

The owners have lost no time in following these suggestions on the sister ship "Olympic." During the past

By means of these lines the reconstruction of the "Olympic" was carried out. The inner skin of the ship to form an inner skin increasing the underwater protection of the "Olympic."

winter the "Olympic" has been withdrawn from service and extensive reconstructions have been made at the Belfast yards. The new clause has been the carrying of the plating of the double bottom up the sides of the ship, as far as deck B. Below the lower deck, the inner skin, as thus riveted upon the frames, will be about 2 feet 6 inches distant from the outer skin of the ship. Between the lower deck and deck B the skin will be about three feet inward.

The importance of these changes will be readily appreciated and the nature of the construction under stood, by reference to the accompanying sketch which shows conditions in the ship as originally built and as they will be when the inner plating has been completed. Formerly a rupture of the outer skin admitted water entirely across the ship. In the future a rupture of this outer skin, unless the penetration were very deep, would admit the water only to the cellular space between the two skins.

Another improvement, which will add greatly to the safety of the ship, is that additional watertight bulkheads have been constructed fore and aft of the bulk spaces, some of which have been carried up to 100 feet above the waterline. The White Star Company is to be congratulated upon the promptness with which it has recognized the lesson of the loss of the "Titanic" and taken steps to thoroughly insure its sister ship against any such disaster.

## Artificial Sponges of Paper

WHEN paper pulp is treated with zinc chloride, it forms a viscous mass. Sodium chlorate (or ordinary table salt) is added to this mass and then thoroughly rinsed with alcohol and is finally submitted to the action of a press whose platform is loaded with a number of fine metallic points or projections. These projections pierce the mass and make them in an ordinary marine sponge known as "caulicrete."

The block thus obtained is of a spongy consistency and is both insoluble and unalterable in water. It is smooth and pleasant to the touch, and is not susceptible of putrefaction. It is a very ingenious employment of the cellulose to which we owe so much.

## Removing Iodine Stains

TO remove iodine stains from bacteriologist instruments or the hands a strong solution of hypochlorite of soda is good and effective. The solution should be quite strong, and after its application the solution should be rinsed off with warm water and the stained article dried well.

Fig. 1.—Jawbone of *Homo Mousteriensis*. Very primitive type from the older glacial drift at Le Moustier, France.

Fig. 2.—Jaws of chimpanzee, Australian native, and European. Note the decreasing area of bony growth behind the front teeth, enlarging the mouth cavity for the development of speech. Also the absence of chin in the first two specimens.

Fig. 3.—Jawbone of *Homo Aurignacensis*. From Aurignac, France. Probably descended from the middle of the glacial epoch.

## New Evidence of the Origin of Man

### The Earliest Known Inhabitant of Great Britain

OF all the chapters of science perhaps none is so romantic as that which contains the fragmentary narrative of the dawn of human life upon our earth. The story is written with skull and cross-bone hieroglyphics, and no sage that ever novelist contrived in his reader can equal that which the student of anthropology feels in the intervals between the successive "instalments" of the serial unearthed, here a piece and there a piece, now in the silt of a river in France, now on the banks of a German stream, or again, it may be, on British soil.

When, in the thirties of last century, Boucher de Perthes first claimed to have found flint implements shaped in glacial times by human hands, he was greeted with ridicule. Since then we have become quite accustomed to placing the origin of man at least as far back in time as the glacial epoch. But our knowledge of the early history of our race is based on all too scant data, and every new discovery of a jaw, a skull, or a more or less complete human skeleton is received with intense interest. The latest addition to our knowledge of primitive man comes from Pittlowden Common, Sussex, England. Here, in the gravels once forming the bed of the River Ouse, but now many feet above its present level, an English paleontologist, Mr. Dawson, discovered, about a year ago, a fairly complete human skull representing the most ancient relic of the human race in the British Isles, and one of the oldest found anywhere. The results of his studies of the specimen have recently been made public. Properly to appreciate the time points of this find it is necessary briefly to recall some of the characteristic features presented to us on the one hand in the highest type of human skull, as represented in modern civilized man, and on the other by the various inferior types known to us in primitive man living or extinct, and in our humbler relatives, the apes.

Considering first of all the jaw we have several interesting points brought out in our illustrations, Figs. 2 and 3. The former shows side by side the jaws of a chimpanzee, a Torres Straits Islander, and a European. Note how in the European the chin is seen projecting beyond the teeth, as seen from above. The chimpanzee and the Torres Straits Islander have no visible chin. This absence of chin, imparting to the face a snout-like appearance, is typical of apes and low races of men, and is clearly indicated in our illustration of the newly found skull (Fig. 6), though unfortunately the part of the jaw carrying the incisor and canine teeth is broken off and missing. Another interesting feature should be noted. In the chimpanzee the bone at the front of the jaw is quite wide, leaving a comparatively small open space in the angle of the jaw. In the Australian native this space is larger, and in the European still more developed. When we remember the importance of the tongue in speech, this point acquires a marked significance.

In profile view, as seen in Fig. 5, several points of interest also appear. The jaw of the ape and lower type of man is much more massive, and the notch in the upper end of the jaw—the sigmoid notch as it is called—is quite shallow in the ape, only slightly deeper in primitive, but is strongly developed in modern man.

As regards the brain case, the feature to which we naturally turn our attention first is capacity or cubical content. In this respect the newly discovered skull does not seem to stand as low in the scale as some specimens previously discovered elsewhere. A graphic comparison of the Sussex skull and the modern type

Fig. 4.—Reconstruction of the Sussex man.

Fig. 5.—Sussex and other typical jaws compared.

Fig. 6.—Skull of Sussex man compared with a highly developed modern type.

is shown in Fig. 6. In this connection it is interesting to quote from Darwin:

"Dr J. Bernard Davis has proved, by many careful measurements, that the mean lateral capacity of the skull in Europeans is 92.5 inches, in (natives) Americans, 87.5, in Asians, 87.1, and in Australians, 81.9 inches. Prof. Broca found that the nineteenth century skulls from graves in Paris were larger than those from the vaults of the twelfth century in the proportion of 1494 to 1400."

Another feature which gives a characteristic measure of the stage of development reached is the facial angle. This has been given as 62 degrees in the Neanderthal man, 57.5 degrees and 61 degrees for two fossil specimens found at Spy, and 56 degrees in the highest ape. Modern man has a facial angle of 80 to 85 degrees. It is the low facial angle, the absence of chin, the prognathous jaw, and the prominent orbital ridges over the eyes which give a characteristic and brutal appearance to primitive man, as pictured for us by Mr. Forester (Fig. 4).

The brain capacity of the Pittlowden man is estimated at 1,070 cubic centimeters (65.3 cubic inches). It is interesting to compare with this the size of brain of some of the largest and most highly developed apes, the brain of the gorilla reaches a capacity of some 54 cubic inches. In this respect, therefore, the Pittlowden skull might be said to stand about half way between the gorilla and modern man—neglecting the fact that the gorilla is more massive in body than man. Nevertheless, the Pittlowden skull represents a considerably higher type, it seems, than the Neanderthal race, which has a much more slanting forehead. It appears, therefore, that at least one very low type of man with a comparatively high forehead was in existence in western Europe long before the low browed Neanderthal man became widely spread in this region. Dr. Smith Woodward, who has been associated with Mr. Dawson in his study of the Sussex skull, accordingly inclines to the theory that the Neanderthal race was a degenerate offshoot of early man and probably became extinct, while surviving modern man may have arisen directly from the primitive source of which the Pittlowden skull provides the first discovered evidence.

One is naturally curious to know the age of the Sussex skull. The geologist is very cautious in estimating the age of fossils in years, but to make a very broad guess, it may be estimated that the Pittlowden man lived some two or three hundred thousand years ago. Since that time the River Ouse has worn down its bed through a distance of eighty feet. The gravel bed in which the skull was found appears to belong to what the geologist terms the Lower Pleistocene age. The gravel consists largely of flints, among which many show signs of having been fashioned by human hands into rude implements. With the flints were discovered fragments of teeth of a Pliocene elephant and of a mastodon. Other remains were identified as belonging to a hippopotamus, a beaver, a horse, and part of the antler of a red deer.

Such are the facts of the case. For those who like to give free rein to their imagination, there is ample scope for exercises in picturing the eventual life of primitive man, battling with wild beasts long since extinct, and, no doubt, engaging also in fierce combats with fellows of his own kind. For the frequent signs of violent injuries found in various fossil specimens attest eloquently to the strenuous struggle for existence that prehistoric man had to wage.

### The Aftel Cloud

THE low-lying coral islands of the Pacific would be difficult objects for the mariner to sight at a distance, but for a curious meteorological phenomenon connected with them, to which attention has recently been directed by William Churchill. In his monograph on "Heater Island," just published by the Carnegie Institution, he says (page 50): "The region of the lowest atolls a sailor's eye can reach in the sky at enormous distances the loom of the land. The lagoon of Atua reflects the sunlight which shines on its unruined surface and casts so distinct a green hue upon the trade-wind clouds which it creates that its existence may be known as far upon the sea as if it were placing the heavens a mile high instead of lying on the waves scarcely as elevated as the sea which shatter in tumult on its reef."

The characteristic green cloud formed over an atoll Mr. Churchill has named elsewhere the "atoll cloud." In a letter on the subject he gives further particulars.

"I have picked up this island (Atua) perhaps a score of times, and the same holds true in varying degrees of other of the Tuamotu atolls. I recall the same observation of Jaluit in the Marshalls, of Lianuila (Ontong Java) off the Solomon Islands, and possibly of yet another great flat in the same neighborhood. My atoll was first directed upon the phenomenon by Polynesian sailors, but as soon as the eye has once caught the appearance of the cloud in the sky it is thereafter as unmistakable as the loom of the land itself. I may describe it as a characteristic pale green tint upon a thin white (fleece cumulus) cloud, the tint being noticeable, but not quite so pronounced as the shade of the California albatross shell.

"Atua is a very typical instance. The lagoon is a still sea with much of its depth under two fathoms. The strand facing the lagoon is so flat that a ripple of no more than half a vertical inch will wet as much as fifty feet of sand. Water temperatures in the shallows have been noted between 55 and 77 deg. Cent. (65 to 91 deg. Fahr.) I can find no record of mean temperatures on the beach, but you will see that they must run high, and, of course, they will prove a potent factor in evaporation when you recall what an acreage is denegated by the higher ripples and immediately exposed to evaporation under the hot sun. Physically we have no difficulty in seeing what happens. We have a large still surface of shallow water with a maximum of evaporating surface upon almost level beaches, a hot sun acting thereon, a flat land with out elevations to interrupt the upward movement of convection. It may enter into the problem that this evaporating surface is surrounded by an ocean of cooler water. Evaporate this big pan, and you have an upward current of air carrying aqueous vapor up to the region where it becomes saturated, and, therefore, this as a superimposed cloud. The still lagoon also serves as a mirror of many miles' area reflecting from its light green surface the rays of the sun."

The same process of rapid evaporation and convection over an island sometimes gives rise to a cloud below the general level of the trade cumuli and differing from the latter in direction and velocity of drift. This phenomenon is described in a letter from Lawrence Hargrave, the Australian inventor of the box-kite.

"Those who understand such things can often tell the position of an invisible reef or shoal by seeing a stationary cloud apparently plunging its way through the ranks of the steadily moving trade clouds. If one be supposed to be above the clouds, this may be likened to a fern-leaved river passing a white stone projecting above the water. When there are no trade-wind clouds, a stationary cloud is still often an indication of reef, shoal, or island."

### New Hangers for Military Uses

By Our Paris Correspondent

THE question of providing suitable hangers for air ships is receiving much attention in military circles in the leading countries of Europe, in order to keep pace with the development of airships for army use. Such

hangers may be divided into two general classes, one of these being a balloon sheet of the fixed and permanent type which is erected once for all and belongs to certain military aeronautical establishments. Up to the present it is the permanent hanger which has received the greater share of attention on the part of designers and constructors, but not less important is the type of movable shed which is also needed as part of the army material in order to give a suitable shelter for airships when carrying out military operations in various places where they may be at a considerable distance from any of the permanent posts. The question of a portable hanger is also the object of research on the part of constructors, and we illustrate one of the most recent ideas of the kind which has been brought out in Italy, this being the Boreu and Bousdell system, and it is worthy of note for several reasons. As several of our engravings show, it has been tried in field work by the aeronautic corps of the army.

The different sections which make up the arches are locked together by using a hinge clamp which is peculiar to the present system. Toothed projections on one piece fit into recesses on the opposite piece like the two halves of a hinge, so that when placed together, all that is needed is to run a pin through the matched holes in order to couple the two pieces.

Each arch is made up of a certain number of sections which are then joined together, and there are two separate blue joints used at the meeting point. After locking one joint as we have seen, this forms a hinge so as to raise the second joint into place and it is then ready to be locked as before by means of a pin so that the two sections are tightly fixed together by means of the two joints. To dismount the sections, the only operation needed is to withdraw the two locking pins so that the joints readily come apart. In this way the arch is built up while it is lying on the ground, and is then ready to be mounted in an upright position. At the proper points on the ground the base plates are laid which form the foot of the arch. Each plate carries projecting lugs in the shape of a half-hinge. These are made to match with a like part on the arch end so as to make the joint. After running a pin through the lugs while the arch is lying on the ground, the last is raised in the upright position by using ropes and pulleys, and when in place, the second joint between base-plate and arch now matches and this is fixed by driving in a pin, so that the arch is now fixed to the base-plate very strongly. The second arch is now raised in the same way, and the two are bound together by cross brace pieces of structural iron work as will be noticed, and so on until the right number of arches is erected.

Another point in the assembling of the hanger needs to be considered, this being the erecting of the structural iron poles or towers which are required in order to draw up the arches by means of cables. It has been a problem to set up such towers in the proper way in field work, as they must have a considerable height in order to serve for handling the arches and at the same time must be very strong in view of the great weight of the arch. The Italian constructors make use of the hinge joint principle in a very good way for mounting the towers. In the first place a short structure (iron pole) is fixed on the ground upon the base plate so as to form the lower and outer part of the tower. It carries a set of pulleys at the top for use in raising the rest of the tower in place. The base plate is triangular, and at each end of the triangle a beam of the tower is fixed by means of a hinge joint. This beam is in reality double, having a hinge placed at the middle upon its height, but both sections of the beam can lie on the ground owing to the hinges. All three beams come together at the outer or top ends and are hinged to a single top pole or cap. The whole can be assembled with the sections lying on the ground with the exception of the top cap, which fits down over the middle post. When the hinge joints are

Arches in the course of erection. The pillars are built up in hinged sections.

## SIXTY-EIGHTH YEAR OF BUSINESS

### To the Policy-holders:

Your Directors assume that, when you think of your contract with this Company, you never question the Company's soundness, but that you are deeply interested in its progress, and in the efficiency and economy of its management.

We submit, therefore, the following summary from the transactions of the year:

During 1912 the Company received in premiums	\$85,941,784.05
In Interest, Rents, etc.	33,301,582.53
<b>Total Income</b>	<b>\$119,243,366.58</b>

### INVESTMENTS MADE DURING YEAR

Real Estate Mortgage Loans (first lien) made in 46 Cities located in 25 States and Countries (to yield 5.32%)	\$34,916,046.00
State, County and Municipal Bonds (domestic, including Canada) issued by 49 Counties and Municipalities located in 29 States (to yield 4.47%)	7,463,101.77
Domestic Railroad Bonds (to yield 4.56%)	3,829,791.17
Foreign R. R., Gov't and Municipal Bonds (to yield 4.21%)	8,234,223.13
Miscellaneous Bonds (to yield 4.73%)	266,777.50
Loaned to policy-holders on security of their policies (to yield 5%)	27,763,909.00

### DURING 1912 THE INSURED OR THEIR BENEFICIARIES RECEIVED FOR

Death Claims	\$25,788,714.50
Matured Endowments	6,167,076.79
Surrendered Policies	12,959,576.80
Dividends	11,436,686.36
Annuities	1,570,562.77
Added to the reserve funds for insurances, to meet the standard adopted by the Company, in accordance with the law, and to the reserve funds for future dividends	31,019,826.00

The increase in the earning power of the Company's assets during the last seven years is equal to 0.29%. Translated into dollars this means an increase in earning power, over 1905, of more than TWO MILLION DOLLARS.

The increased earning power developed in 1912 is notable. It is represented by 9/100 of 1%, and, if maintained, will increase the income of the Company in 1913 by comparison with what it would have been had the earning power remained as at the close of 1911, by the sum of - - - \$647,000

Of the amount which the law allowed us to spend in 1912 for new business, we actually spent . . . 91%  
 Of the amount which the law allowed us to spend for all purposes, we spent approximately . . . 63%  
 Of the amount of new business which the law allowed us to issue in 1912, we issued . . . 100%

## EASIER FARMING MEANS CHEAPER FOOD

Power-Value  
of Horse  
and Tractor  
(1 to 30)

The most urgent and important problem in the development of industry, is EASIER FARMING. The Farmer must have a better percentage of result. He must be able to handle more land and to handle it in a more efficient way. EASIER FARMING—that is the platform of the RUMELY COMPANY. For sixty years this Company has made Power-Farming machinery. The famous Oil-Pull Tractor was born in the Rumely factories. So were the other Rumely engines, and rollers, and tank wagons and separators. All told, there are now

### 51 RUMELY MACHINES

These Rumely Machines are all designed to cut down the cost of living. They mean cheaper bread and cheaper meat.

Whether you are a farmer or not, you should know the House of RUMELY.

## Notes and Queries

Kindly keep your queries on separate sheets of paper when corresponding about them. Send them to the Editor of the Scientific American, 375 Broadway, New York, N. Y. They will be printed in the Notes and Queries column of your issue. They will be printed in the Notes and Queries column of your issue. They will be printed in the Notes and Queries column of your issue.

12720) F W M asks: An upright, light, heating drum, 2 feet high, 1 inch diameter, having a 1/2-inch top connection, one damper to chimney and handle on bottom of drum a ring burner of 14-inch pipe for gas, with Rumely air intake taking air from outside, and also a 3-inch bottom connection to take in fresh air into drum. The gas will not burn in the ring burner inside of drum. It flows out. Why? A. If your Rumely burner has a greenish color at the bottom of the flame and vibrates and wags out, there is not sufficient air furnished by the mixer. There should be an adjustment to control the amount of air admitted to the gas so that the burner will burn quietly and with a flame whose coloration when seen in a lighted room.

(12727) J W asks: I would very much like to know if there is any truth in a certain French chemist, who states that he has made the diamonds in the rough. I have seen a great deal in an editorial I have forgotten whether it was in your paper or some other paper of the being done, and told it to be a fraud. I think it cannot be done. I would be very much obliged if you would let me know about it. A. You are not mistaken. It is not possible to make diamonds artificially. This process is described in Scientific American 1561 1562 1563. The only one who has created a diamond by no means an authority than Prof. William Crookes. These stones are very small, however, the largest being about three thousandths of an inch across. They are considered to be real diamonds, and it would not be long before some time large ones may be made. The "certain French chemist" is none other than the famous M. Moissan the man who has shown revealed the use of the electric furnace. We should say there is truth in any claim he may make.

(12728) P M asks: I Why this sun appears to set at one hour or may about December 15th than it sets December 21st or 22nd the winter solstice. A. The sun does not set at one hour as it is seen before noon all the time, every day in the year. The clock, however, does not stand at 12 at noon on any day of the year, with the exception of four days, about April 15th, June 15th, September 1st and December 25th. But the sun sets a little from noon to your party because of the extra day inserted in leap years. The subject is an extensive for discussion in a letter and is explained in all the text-books of astronomy under the caption Equinox of Time. You can find in your city library find Todd's "New Astronomy" or Young's "Manual of Astronomy" either of which will cover the subject. 2. Why is that at certain seasons the sun rises later every day, but, at the same time sets at the same hour and minute, over a period of say 9 or 10 days? A. Your second question is answered by saying that sunrise and sunset are calculated and given in the almanacs for the real sun, but the clocks do not keep the time of the real sun since the apparent motion of the real sun is not uniform day by day. Hence the apparent difficulty, which is explained in Todd on page 113 under the heading Rotation of Rumely near the Winter Solstice. Should you wish to own either or both of these valuable books, we can furnish Todd's "New Astronomy" for \$1.45 and Young's "Manual of Astronomy" for \$1.00, and shall be pleased to receive your order. We thank you for your expression of appreciation of our astronomical articles.

(12729) F M asks: How are trees splintered by lightning? Not long ago I examined the result of lightning on a large tree. Some large limbs that lay on the ground showed that small twigs and limbs had a hole bored in length just under the bark. I could not find any entrance or exit holes, but closely observed this hole in the section, and observed was not in evidence. I took several of the sticks home, but cannot find them now. When the current passed at the trunk, it was too much for the carrying capacity and splintered the wood in seeking an onward path and the limbs fell. Was not the tree a tree long dead and dry, it would have been splintered much worse. Lightning follows the fiber of the timber the true is dead or almost, crinkled in the limbs and more or less activity in the trunk. The great marvel however bark, light, and electricity are not so much a mystery. Why could not the vibrations of electricity convert themselves on a poor conductor sufficient to use it as a wire? A. We thank you for your observations upon the action of an electric discharge upon the wood of a tree. It is all very interesting, and is explained by the discharge of a heavy charge of electricity upon or through them. The trees and wood generally have no resistance to this general effect. Conductors are not too solidified, since they allow the electricity to pass through them without resistance. The tree has a non-conductor, that is, the power a conductor is material in the tree is in the sap and in the leaves. The leaves, bark, and electricity are repelled by resistance as non-conductors of one matter, electricity is repelled by even more. All these things are explained in your issue. Lightning only strikes in the neighborhood of its discharge.

## PATENT ATTORNEYS

If you have an invention, which you wish to secure from any writer fairly and quickly to Henry C. Mun & Co. for advice in regard to the best way of obtaining protection. Please send sketches or a model of your invention to our New York office, the above, explaining its operation.

All communications are strictly confidential. Our vast practical experience, covering a period of more than sixty years, enables us to give you advice in regard to patentability without any expense to the inventor. Our New York office is sent free on request. This enables our clients to obtain the best advice in regard to their PATENTS. TRADE MARKS, FOREIGN PATENTS, ETC.

All patents covered through us are described without cost to the patentee in the SCIENTIFIC AMERICAN. MUNN & COMPANY

## The $\frac{3}{4}$ Ton Utility Truck—\$1250

(Chassis Only)

**T**HIS new Utility truck is the most practical and serviceable truck of its size ever built.

It is intended for any kind of city and suburban delivery service. It works more simply, more economically, more rapidly and more effectively than most trucks of much larger size. It is a new development.

Unlike the average small truck, it is *not* a built-over or a redesigned pleasure chassis. It is a real heavy truck in all of its parts, in its entire design, in its whole construction and in its economical operation. For instance, the powerful 4-cylinder motor is controlled by our patented governor; it cannot be driven over 18 miles an hour; it has quick demountable solid tires 36" x 3" front and 36" x

3½" rear; it has an unusually rugged pressed steel frame, doubly reinforced at points where it will receive the greatest strains; the wheel-base is 120 inches.

Throughout this truck is built on the most modern truck lines. It is made in one of the largest truck plants in the world by men who have been building successful trucks for over ten years. It is built by truck specialists.

For the merchant or manufacturer who has a whole lot of daily deliveries to be taken care of, this new Utility truck is well worth immediate investigation.

See the nearest Gramm dealer, or write us and we will send you one of our transportation experts.  
Literature and transportation advice from the factory—gratis.

See this new truck at the Chicago Truck Show  
Section D, Coliseum

## The Gramm Motor Truck Company, Lima, Ohio

John N. Willys, President

### BRIEF SPECIFICATIONS

**CARRYING CAPACITY**—1500 lbs. Maximum, 2000 lbs.  
**BODY**—Optional and extra.  
**FRONT AXLE**—4-Wheel Section.  
**FRONT AXLE**—4-Wheel Section.  
**FRONT AXLE**—4-Wheel Section.  
**FRONT AXLE**—4-Wheel Section.

**MOTOR**—4 cylinders, 4 to 6 in. stroke. Provided with enclosed and sealed governor.  
**TRANSMISSION**—Selective type. Three speeds forward and one reverse.

**WIDTH OF FRAME**—34 inches.  
**WHEEL BASE**—120 inches.  
**TIRES**—Front, 16½", Rear, 36½".  
Goodyear Solid.  
**LOADING SPACE**—Approximately, 6½ inches x 96 inches.

**GASOLINE CAPACITY**—20 Gallons.  
**EQUIPMENT**—Two side oil lamps. Oil tail lamp, horn, and full set of tools.

## G. V. Electric Trucks

For Manufacturers

The illustration below shows a 5-ton G. V. Truck recently delivered to the Wall Rope Co. 48 South Street, New York.

They thought this matter of Motor Trucks over very carefully before buying and when they did buy the order went to a pioneer manufacturer whose experience warranted a good truck—and whose financial standing argued well for the right kind of co-operation in years to come. Other trucks will be ordered for the works in New Jersey

We recently delivered a smaller 5-ton truck to the Central Stamping Co. of New Jersey and another to the National Sugar Refining Co. The General Electric Co. uses G. V. Trucks in its various plants. Other users are: The A. B. Se Elevator Co., Brown & Sharpe, Franklin Mills, Canadian Rubber Co., Calumet & Co., Globe Wrenn Co., Janney Mfg. Co., Model Sales Co. (truck company), National Cash Register Co., Singer Mfg. Co., Standard Paint Co., Winchester Repeating Arms Co., Manning, Maxwell & Moore, and many others. It is a great mistake to ignore G. V. Trucks for growing profits because they ought to be saving the manufacturer thousands of dollars per year. We have seen customers who haven't a single horse. One of them still adds 176 horses in three years.

## The Motor-driven Commercial Vehicle

This department is devoted to the interests of present and prospective owners of motor trucks and delivery wagons. The Editor will endeavor to answer any questions relating to mechanical features, operation and management of commercial motor vehicles.

### Business Getters for Small Concerns

By Charles H. Spencer

BEFORE the experiment was made the small user considered the motor truck out of his reach. When the motor truck salesman called the usual response was, "Let the big fellow do it. We can't. They have to do things on a big scale. Their plants are large. They can afford to get fleets of cars to hire skilled and expensive men to take care of them to buy gasoline at reduced rates and to profit all along the line by purchasing in volumes reaping the benefit of cost reduction by so doing. There seems to be plausibility and business discretion in this argument until analyzed. Then it will be found that the nearly every proposition which is opposed to progress it is based on an unsound reasoning. The business man who resigns himself to a small volume of business and is not concerned in installing facilities for handling an increase is never likely to get the increase.

Customers Beyond the Horse's Reach. The city merchant not equipped with the commercial vehicle is now finding himself compelled either to abandon the effort to secure the business in the suburban trade or to expand a sum of money in horses and suitable wagons that consume his profit and make his venture unprofitable. The man using horses has to limit himself to the area in which the animal has to deliver. Further than this the country is closed to him. There may be thousands of customers beyond the bound any line of the horse's power. It is generally agreed that a ten mile radius is all at the limit in which it is possible to use a horse-drawn delivery system. If the time a horse has hauled a load for a mile made many stops and completed the ten mile journey took it has done about all the work possible for him. When any more than twenty miles daily is placed on the animal it is done at a risk it means perhaps the collapse of the horse a dead loss to the owner and permanent impairment of his delivery system.

The electric vehicle ideally adapted to quick delivery within the city limits or to suburban points is good for a radius of from twenty to twenty five miles a day going and coming and finally a gasoline propelled motor truck is in many instances delivering at distances of fifty miles from its starting point which means that it covers a delivery route of one hundred miles a day.

### A Wholesale Grocer's Experience

A short time ago the writer's attention was called to a wholesale grocer who decided he did not have enough customers to support the overhead expenses of his store. He decided to create a small field of action and for this reason he placed out a truck. He was prepared to have it cost him a little more money just as he believed in spending additional money for advertising or increasing the salary of a productive salesman. The results he obtained were very gratifying in furthering his truck went where his horse never before could reach and he found that there was business waiting in sections he little dreamed of. He put on more mileage who in this way were given the advantage of being able to promise prompt deliveries than they had been able to maintain before. The increase was so great that the profit was big that this particular grocer was obliged to put a new truck into service to care for the gain.

We know of a similar instance with a small retail concern that was competing with a large concern, using horse drawn vehicles. In less than a year's

time after introducing a commercial truck he was able to purchase an extra car and is now making wonderful increases in his business, and inroads into the trade of his competitor through his ability to serve his patrons more promptly.

Another instance is of a retail grocer who found that a 1½ ton commercial vehicle displaced four horses and two wagons. This concern averages sixty miles per day now by the use of the motor truck and has extended the business territory of the company to a surprising degree. New customers have been made and held by the promptness of delivery secured and the residences situated in unfrequented sections are reached where these were formerly a problem of great difficulty being visited weekly where now the motor truck calls daily.

### Making Chauffeurs Out of Drivers.

Many business men are deterred from buying motor trucks for fear their wagon drivers will be made chauffeurs. There is no more intelligence required to operate and take care of a car than to take proper care of a horse. There are a few motor truck manufacturers who conduct special schools to train drivers at their different service buildings located in the various large cities of the country and it is their experience that the average chauffeur can be readily educated to operate a car. One concern turned out last year over fourteen hundred students in one of these schools who were formerly drivers and reliable delivery men used in the days of the horse-drawn vehicle.

### The Right Car for the Purpose.

It has been found in many instances that a merchant has paid too little for his motor truck. He has purchased a car too light in construction to withstand the daily delivery grind or too large for the particular handling of his merchandise. There are over two hundred and fifty firms engaged in the manufacture of motor trucks in this country and it requires little effort to secure practically all the needed information regarding the particular type of truck that is meeting with success in the line of business in which the merchant is interested. On looking carefully into the subject it is usually to be found that the best car for a particular line of business is the type that is already represented in greatest numbers in that line.

### Steel Tires in France

To the Editor of The Motor Truck Department

In the article on Subsidized Motor Trucks appearing in your issue of Sept. 29, 1914, it was stated that the French government was very misleading for the reason that it was incomplete. It referred to the French government test, and the assertion was made that "not one of the trucks about all around with steel was able to qualify. The author evidently did not know that this applied only to trucks of three tons capacity and less, in other words light trucks intended to be driven at speeds of about twenty miles per hour. The Hon. S. Fay former president of the American Society of Automobile Engineers, who carefully investigated the French army test of steel tires, said: "Not a few makers of automobiles maintained that pneumatic tires would be even cheaper and better in the long run than solid rubber tires, thus suggesting strongly that steel tires were not the solution. The fact that the French army had its way and their decision has had a marked influence on commercial transportation in France. Secondly, possibly all French trucks equipped with steel tires are now being used for military purposes." This is a very interesting and important point.

## Seven Million Watch-Towers in the Bell System

The original campaign were the watch-towers of old Venice guarding the little republic from invasion by hostile fleets

Later, bells were mounted in these same towers to give warning of attack and celebrate victories

Judged by modern telephone standards, such a system of communication seems crude and inadequate

In the civilization of today a more perfect intercommuni-

cation is essential to national safety, convenience and progress

The Bell System binds together a nation of nearly one hundred million people, by "highways of speech" extending into every nook and corner of this great country

Seven million Bell telephone stations are the watch-towers which exchange, daily, twenty-five million messages for the happiness, prosperity and progress of all the people

## A HISTORY

OF THE

## AMERICAN PEOPLE

(In Five Volumes)

By

## WOODROW WILSON

ONLY those who have heard President Wilson speak can imagine faintly the brilliancy of his writings. It makes history living, it revivifies the past like a great drama. It paints in gorgeously colored words the epochs in our career. It is so fascinating that any novel

He tells the story of our people of their struggles, their hopes, their progress. It is distinctly a human history giving preference always to man rather than to documents to deeds rather than to theories. It rivals the strongest fiction in point of rapid action, it is as dramatic as a play and withal it has the accuracy acquired by a quarter of a century of scholarly research and painstaking study.

In addition to the many maps, portraits, and rare prints the work is rich in illustrations contributed by Howard Pyle, Frederic Remington, H. C. Christy, F. C. Johnson and others of world wide reputation.

To read the first page is to read the five volumes

## WE NOW OFFER

We will send you the entire set of five volumes, all changes paid, on receipt of \$5.00, and enter you at once in a subscription for both HARPER'S MAGAZINE and HARPER'S MONTHLY. Harper & Brothers

claimed for the motor in front under a bonnet. This construction brings more of the load weight on the rear axle, where it properly belongs and can be readily cared for enabling the use of lighter spring suspension in front, where the power and driving mechanism is located, both of which need to be relieved of as much as possible. It provides easier handling of the vehicle and a more accessible power plant. In its new specifications pertaining to motor trucks eligible for mobility the British War Department bars all vehicles not having motor in front.

IN the "SCIENTIFIC AMERICAN" of October 30th 1912 was an article by Mr. Morris Hall on the delivery service of New York's department stores in which it was stated that the saving of the trucks over horses was found by Stern Brothers to be \$1012 a year for each motor driven unit. The figure should have been \$2119

## Moving and Talking Pictures

(Continued from page 6.)  
the film after exposure. The Court of Appeals for the Second Circuit (see 351 F. R. 107) held claims 1, 2 and 3 valid but not infringed by a camera in which the film is moved by frictional contact alone although such construction is within the terms of its construction without reference to the words substantially as described. But they held these claims were infringed by a camera in which the film is moved by a reciprocating two-toothed fork carrying studs or pins which engage perforations along the edges of the film. This construction was considered the substantial equivalent of the sprocket wheel of the patent claim 4 was held void as too broad. It differed from claim 5 of the original 1 by the additional words "the periods of rest being greater than the periods of motion."

The relevant patent was again released No. 13,720 with five claims. Claim 1 and 4 thereof are the same as the corresponding claims of the previous release (claim 4 differs from claim 1) in stating that the machine moves the film in a direction to cause the device to so advance the film that its periods of rest shall exceed its periods of motion. Claim 5 differs from claim 1 in stating that the film is perforated and specifying that the feeding device is provided with teeth engaging the perforations of the intermediate section.

In a suit brought by the Motion Picture Patent Company (owners of the patent) against the Chicago Film Exchange the validity of the renewed Edison patent was again passed upon. The lower court held the claim covering the photographic film infringed but on appeal the decision of the lower court was reversed the court taking the position that the long patent transparent celluloid film with the serrated surface was the invention and improvement of others. The pictures taken on such a film are photographs. The invention of Edison was exhausted with the construction of a camera which enabled the photographic of moving objects to be taken on the Eastman film in the distinct, uniform and satisfactory manner justly claimed for them. The pictures taken are the direct result of the mechanism of the camera with the Eastman film mechanically adapted to and applied thereto. The perforations along the edges of the film at regular intervals into which perforations the teeth of ratchet wheels are required to give it the required motion was regarded as a mere mechanical contrivance devoid of patentable novelty.

A large number of patents have been granted for various improvements in motion picture mechanism, and to describe them all would fill a large volume. An interesting example is patented by R. D. Gray, No. 1,540,566, June 4th, 1924. Referring to Fig. 4 of the claim D is shown passing from the reel P to the reel L. The film carries two series of sprockets, the individual sprockets being made of metal on opposite sides of the sprocket line of the film and through a single line

B. A segmental mirror *B* shown in elevation in Fig. 8 consists of a half circle of silvered glass, the other half of which is transparent. This mirror is rotatably mounted so that its plane of rotation intersects the axial line of the lens at an angle of forty five degrees, and thus during each rotation the light is alternately allowed to strike the film at *C* and then reflected to strike it at *C'*. The film guides are so arranged that the exposures at *C* and *C'* are on opposite halves of the width of the film. The film is advanced intermittently by two rods *p* and *p'* operated by cranks, the free end of each rod being forked and the two bent at right angles to engage perforations along each side of the film. The forks act alternately so that while the film is being exposed while at rest at one place it is being advanced at the other. For projection, a device similar to the camera is used with the addition of two lamps, one in the axial line of the lens opposite *C* and the other at right angles thereto opposite *C'*. The motion picture machine and the photograph have both reached a high degree of perfection. The next step is to connect the two machines so that they operate in unison. Motion pictures unaccompanied by sound give the effect of pantomime. On the other hand, the effect produced by the photograph alone is in many instances as unsatisfactory as the effect produced by motion pictures when they cannot be seen by the audience. The combined effect of motion pictures and photographic reproduction is necessary to give complete illusion. For this purpose, substantially complete synchronization between the two machines is necessary. In order that each movement shown upon the screen shall be accompanied by the sound originally produced simultaneously therewith. Attempts have been made to accomplish synchronization by mechanical connections between the two machines and also by connecting them electrically. It is claimed that mechanical connections are not perfect, the slightest slip between the parts or any inaccuracy in construction destroys the synchronism. As for electrical connections, it has been stated that the cost of equipment and maintenance of special electrical apparatus is prohibitive. It is that as it may be the fact remains that in spite of repeated efforts for a number of years, this feature has not as yet been placed on a practical commercial basis. Mr. Edison claims to have solved the problem in his recently exhibited kinetophone, but he is unwilling as yet to publish the technical details of construction. The patents along this line are all of rather recent date. The patent to Grammont, 782, 814, February 18th 1904 discloses an example of synchronizing by electrical connections. Referring to Fig. 7 the photograph is driven by a constant speed by any desired motor *Z*. The motion picture machine *A* is driven by a motor which has the coils of rotor *B* connected to a source of electrical energy *I*, while each section of the stator *A* is connected with a section of the collector *C*. This latter connection consists of insulated wires formed into a cable *O*. Brushes *D* and *E* are rotated around the collector by the gearing *K* connected with the photograph. The said brushes are connected to insulated rings *a* in contact with brushes *d*, connected to the two poles of a source of electrical energy *I*. When the brushes *D* and *E* are rotated, corresponding polarities are produced in the stator *A*, the law of displacement of which is the same as that of the brushes. Consequently, the rotor *B* will exactly follow the movement of the brushes which are positively driven from the photograph. In operating this apparatus the photograph is started with the motion picture machine disconnected. At the exact moment when the prearranged signal is given by the photograph, the motion picture machine is started by means of the clutch *F*.

A MAN feels more responsible and self-respecting while attending to a machine than when acting the part of a chambermaid to a hotel in a lively stable.

**Do You Know Actual Costs?**

If your price is too high, your competitor underbids you. If your price is too low, you undersell yourself. You lose, and your losses grow bigger with your business. Today the growing merchant has actual cost knowledge. His purpose in finding costs is to reduce them. Reliable figures of cost are always analyzed. They locate losses and wastes. Figures reduced to the language of costs usually shout loudly for reform.

**Jones Recorder for Motor Trucks**

supplies accurate data to determine delivery costs. Motor trucks are big investments. Delivery costs are out of the maintenance and depreciation of the trucks. The charges must be reduced to unit figures to be distributed to each unit of product. There is only one way—have complete performance records of every truck.

By the Jones Recorder every movement of the truck is registered on a graphic chart. Every operation of the truck is visualized. It tells every speed, all the distances covered, the number of stops made, the length of the delays, the time of each loading and unloading interval, and the time of departure and return.

Such reliable and immediate knowledge discovers leaks and permits every organization to move its goods efficiently. In connection with fuel, oil and tire consumption records overall delivery costs are found, and when actual costs are known cost-reduction is usually effected.

The Jones Recorder is enclosed in a handsomely finished case of heavy brass. It is connected to a gear on the front wheel by flexible shafting. The recording mechanism is shown on the chart and recorder to obtain accurate cost-reducing records for your trucks.

We would be glad to supply more complete information

Here is the latest triumph of a company which has originated practically every improvement in electric vehicle construction. That has factory equipment for the manufacture of every type of electric vehicle, from the smallest runabout or brougham to a mighty five-ton truck.

—And a whole experience, gained in the making of this unlimited range of electric vehicles, enable them to evolve this most elegant, comfortable, and convenient of all four passenger electric.

### The Silent Waverley Limousine-Four

In this wonderful car four separate Pullman chairs replace the usual forward and backward seats. Three face forward, the fourth is a "cay corner" in front at the right. Thus affording full four-passenger capacity without obstructing the view of the driver, who sits as usual in the left-hand rear seat—the pleasant and sociable position, with, instead of in front of the other occupants of your car.

This arrangement insures ample and the delightful spaciousness and absolute freedom from crowding—no crushing of handsome gowns and wraps in the Waverley Limousine-Four—while permitting of greater luxury and greater elegance than has ever before been possible in a four passenger electric.

The little diagram shows this unique placing of seats, and how golf clubs, parcels, bags, etc., can be stowed out of the way behind the two side chairs. A small item, perhaps, but one that adds greatly to comfort.

Waverley patented drop-all construction permits of a beautiful, graceful low hump body over its full elliptic springs as shown in the illustration—a combination which insures easy riding over every road and with any tires while saving current, increasing mileage and

protecting your car from racking bumps and jars.

Batteries are flushed from outside the car—no lifting out of cushions with greasy hands, no spotting with water or fabric-eating acids.

The Limousine-Four will be on exhibition at the leading automobile shows, where prospective electric car owners can personally judge of its perfection—

—and decide if such a splendid car the last word in four passenger electric, could have been designed and perfected except by past masters of electric vehicle construction—men who from long experience know the mechanical requirements of every type, from the most luxurious pleasure car to the massive delivery truck.

Let us send you the Silent Waverley Electric Year Book, which illustrates and describes the Limousine-Four, the famous Limousine-Five and the other Waverley pleasure car models illustrated in the left hand page.

A beautiful production with decorations by a famous artist—it is yours on request, together with the Waverley Commercial Car Catalog, showing prices ranging from a light delivery wagon to a five-ton truck. Address

THE GREAT HORSE RACE SCENE IN THE WHIP —[See page 59]

Night horses ridden by jockeys take part in the race. Each horse runs on a treadmill. That of the winner and one other horse are pulled forward at the finish. Five gramophones (four of them can be moved around the stage) are actuated by individual motors.

## Engineering

**A Turbine- and Reciprocating-engine Competition.**—What a fine opportunity for judging the relative efficiency of the turbine and the reciprocating engine was afforded by the recent run of the "Arkansas" and "Delaware" from Colon to Key West at a speed of 18 knots. The reciprocating engine of the "Delaware" has some fine records to their credit, and since the "Arkansas" is fitted with the latest type of turbine, the run should afford some excellent and most valuable data as to the relative efficiency of the two types, at least at a speed of 18 knots.

**Removing Railroad Grade Crossings.**—In view of the growing number of fatalities at grade crossings, the Legislature of New York State has taken into serious consideration the recommendation of the Public Service Commissioner of the Second District that \$500,000 be appropriated for eliminating grade crossings of highways and steam railroads. It will surprise some of us to learn that there are at the present time over eight thousand of these crossings in the territory which is covered by the Commission of the Second District alone.

**Bolidizing of the Gates Dam.**—According to that excellent publication, the *Canal Record*, the hydraulically-deposited core of the Gates dam is now practically covered in by the detritus of the debris of the Mississippi, which is a highly water-proof, has been found very interesting in the rock and earth, until the whole mass at the center of the dam has become like a rubble wall, every rock of which is cemented to another. This is similar to the boulder concrete of the concrete dam, and the *Record* states that it is probable that in time the core of the dam itself will solidify into such rock.

**One-man, Gun-fire Control.**—The ideal method of firing broadsides from a battleship would be one in which all the guns were given the same training and pointing, simultaneously by one man—provided of course, he is possessed of better training and elevating abilities than the average of the ten or a dozen separate men who do the work at present. Sir Percy Scott has perfected a system by which all the guns can be trained and elevated simultaneously by one man from a single station. The latest report states that this method has shown a great superiority in target practice over the old system of separate pointing and training.

**Large Dipper Dredges.**—The excavation of the Atlantic entrance to the Panama Canal called into service dredges of unusual size. The "Mildred" and "Chagres," which are cutting the entrance channel to a minimum depth of 42 feet at mean tide, are working entirely in rock which has been previously broken up, and they bring the material to the surface in 5-yard dippers. The dipper handles are 10 feet long, and the boom supporting the dipper shaft is 50 feet long. To facilitate the work the dredges have been equipped with steam dipper trips which have shown good results during six months of work.

**High-speed Trains in Germany.**—The 1912 summary table of the German Railway Systems, says *The Engineer*, provides an interesting story, for it reveals that a new era of rapid transit has dawned in that country. In 1911 a non-stop run from Berlin to Hamburg in three hours and twenty minutes was inaugurated, and in 1912 the run was further accelerated. The train left Berlin at 8:25 P. M., reached Hamburg, 178 1/2 miles distant, at 12:50 A. M., the speed being 55 1/2 miles per hour. The return journey was made at 54 1/2 miles per hour. The train was a light one, consisting of four four-axle coaches and a six-axle dining car.

**Safety Railroadings.**—The Pennsylvania Railroad, co-operating with other lines in the eastern territory, has inaugurated a railroad safety movement, which is the latest move of many made by the company to increase the safety of passengers and employees on its system. "Safety First" meetings are to be held in several important centers, in which lectures will be given with lanterns, graphs, lantern slides, and statistical tables will be delivered. We are glad to note that other leading railroads are moving in the same direction, for we regard this "Safety First" movement as one of the most effective measures for reducing our present shocking annual railroad list of killed and injured.

**The Gas-electric Motor Car.**—Railway officials have been watching with interest the development of the self-propelled car for use on steam roads. Under steam operation, short branch lines, carrying a limited traffic, are not only uneconomical, but they are also a constant safety hazard. It is believed that the use of self-propelled units at frequent intervals give a more satisfactory service than the larger once-a-day trains, and the managers have turned to the self-propelled car as offering a solution of the problem. To-day over twenty railroads have self-propelled units of various types running on regular local schedules. The consumption of gasoline, while varying with the local conditions, is found on the average to be low, the economy being due to the electric transmission, which lends itself admirably to the particular requirements of local service.

## Science

**A Yearbook of Agricultural Statistics** is the latest periodical publication to be undertaken by that remarkable profile institution, the International Institute of Agriculture, which in its initial volume, published in 1912, gave statistics for the years 1910-1911. It contains fifty countries adhering to the Institute, representing practically the whole of the civilized world. All the data are from official sources.

**The Rice-growing Congress.**—The fourth international congress of rice growing was held at Vercelli, Italy, during the early part of November. It was decided to establish an international center for rice cultivation and researches upon this subject and accordingly the Vercelli rice-growing plant is to be reconstructed and laid out with this end in view. The invitation will be directed by Prof. N. Novelli and it is expected to further the interests of this branch of research to a considerable extent.

**Feeding Plants to Keep Them Warm.**—It is well known, of course, that human beings and the lower animals are better able to resist cold when they are well fed, but it is interesting to learn that a German investigator has announced that feeding plants has the same effect on them. He declares that the introduction of organic substances of nutrient character (carbohydrates, alcohols, etc.) into the plant cells helps them to resist cold, even in the case of tropical plants. Different substances protect in different degrees. The sugar stands highest, then come glycerine, the alcohols, and acetone. The removal of the protective contents restores the original degree of resistance.

**Amundsen Receives a Gold Medal from Peary.**—On January 11th Capt. Roald Amundsen, discoverer of the South Pole, received from the hands of Rear Admiral Robert Peary, discoverer of the North Pole, the gold medal of the National Geographic Society. Replying to the brief speech of presentation, Capt. Amundsen said: "Greatly as I am honored by receiving this beautiful medal, I feel that the honor is multiplied a thousandfold by the fact that the presentation has been made by the greatest explorer of our age, Rear Admiral Peary. The desire to reach the South Pole, in fact, the spirit for exploration and discovery, was awakened in me by Admiral, then Lieut. Peary, whom I met in the Arctic in 1890."

**Right and Left Handed Plants.**—Do you know that the plants of the world are divided into right and left handed? An English investigator, R. H. Compton, has thought the matter curious and interesting enough to make it the subject of extended investigation, and has reported on it to the Cambridge Philosophical Society. He observed that the majority of two-cotyledonous plants have the ratio of right to left, in the first leaves of seeds of different varieties and of the various races from the same individual species, and found that among 12,401 seedlings 7,257 or 58.5 per cent had the first leaf twisted to the left. A variety of millet showed a excess of left handed seedlings as was also the case with oats. In the case of corn, the ratio was almost unity, and there was apparently "no inheritance of right and left handedness as such."

**The Meteorological Service of Brazil** has been completely reorganized and placed under the Ministry of Agriculture, Commerce and Industry of that country. About 150 stations are already in operation, and it is planned to greatly increase this number by having each State establish a central observatory and by increasing the number of cooperative with the central institution in Rio Janeiro. Several stations will soon be established in the remote interior, at places to which access is slower and more difficult than a journey to Europe. At present nine tenths of this vast, remote, and unexplored territory is without a meteorological station, and the climatic changes of the globe. The shining exception to this condition of affairs is the famous coffee-producing State of São Paulo, which has long maintained an excellent meteorological service on its own account. The director of the new national service is Prof. Dr. Henrique Morice.

**Expeditious to the Karakoram.**—Dr. Filippo di Pilupp, well known as an associate of the Duke of the Abruzzi in his mountaineering enterprises, is preparing to lead an expedition to the Western Himalayas to investigate the Karakoram, which will probably be the most important undertaking of its kind ever conducted in that region. The proposed route lies from Kashmir over the Himalaya range and through Baluchistan and Ladakh into Chinese Turkestan. The problems to be investigated concern topography, geology, gravity, magnetism, and meteorology, including the various forms of radiation and atmospheric electricity. The upper air is to be sounded with kites sent up from stations of high altitude—a method of great interest and value. It is expected that the Himalayan explorer will be able to start his kite at a level corresponding to the greatest heights above sea-level heretofore attained by the kite itself in other parts of the world. The estimated expense of the expedition is \$50,000, of which \$35,000 has already been raised.

## Aeronautics

**A New Height Record in an Aeroplane.**—On January 10th Maurice Chevalier made a new world's record for three passengers. He rose to a height of 4,921 feet. The ascension was made at Buc, France.

**A Life Saver for Airships.**—Pascualo Ribault, of Los Angeles, Cal., has patented No. 1,045,023, a safety device for airships in which a collapsible parachute cover is opened by a spring and frames fastened to the airship fold over the parachute cover and are held by a latch to reserve the parachute out of operation until necessary for its use.

**A Novel Envelope for Aerostats.**—John R. Gammeter, of Akron Ohio has patented, No. 1,047,158, an envelope for gas containers, for aerostats, composed of a fabric woven of metallic ribbons and he forms this envelope with a body portion of lightness woven in metallic ribbons and with end portions of sheet metal the ribbons being woven so that they present substantially no interstices.

**Flight Across the La Plata River.**—At a remarkable flight of 120 miles over water was made from Buenos Aires to Montevideo on the 2nd inst. by Corporal B. The distance covered was 120 miles and the time of the flight something over two hours. The flight was made down the river, which is 80 miles long. The young man, a corporal is a student of engineering who is doing one year of military service. He pilots a Blériot monoplane.

**Curtis Flying-boat for the Army.**—The flying-boat built by Glenn H. Curtiss has been a satisfactory machine at Hammondport, N. Y. In the climbing test, the machine rose to an altitude of 1,200 feet in 6 1/2 minutes. The average speed was 54 1/2 miles an hour in a 10-mile wind blowing diagonally across the course. During a two-hour duration test, a total weight of 900 pounds was carried, which included the weight of the aviator and passenger.

**Testing the Two-engine Principle.**—According to *Flight*, Laur Sædén on the Short two-engine biplane recently ran from Luleåhamn to a height of 4,000 feet. Then coming down to 900 feet he cut off one engine, and made a flight of about 9 miles to the south of Sheppey and Layslow, finishing up with a volplane from 500 feet. It has been stated, as a result of this experiment, that should one motor fail at a height of 5,000 feet, the machine would be able to travel a hundred miles without alighting on the water.

**An Air Scout Killed.**—According to a dispatch published in the *New York Times*, a war aviator, Dr. Jules Constantine with the Bulgarian army was killed in battle. On his first flight he was shot down by a Turkish plane before the Thracian lines, in a biplane, and he was killed, as appeared from a view. When the machine returned and descended, his comrades found him lying dead on the ground with a wound in his chest. The wings of his biplane were visible. The machine showed that he had attained a height of 4,000 feet above the Turkish forts. He had just gained enough strength left to guide his machine toward the Bulgarian camp.

**Italian Aviation.** The Italian army is coming to the front in the use of hydroplanes and among other performances we may mention the brilliant flights made by Lt. Cimmino upon his Paulhan machine at Venice alighting at times amid the *numerosi gondolieri* Paulhan, who was on a visit there also made flights before the Italian officers. The government is taking up the hydroplane with a view to its use in installing aeroplanes posts all along the coast. It intends to use Borch hydroplanes quite extensively and has ordered nine of these to be delivered to the Venice arsenal in three months. The first hydroplane fleet in Zeppelin type is expected to be ordered by the Italian Government to make evolutions over the Adriatic. On the other hand, the Austrian war department has just ordered one of the newest Paulhan-4-rotors hydroplanes known as "flying boat."

**Hydrogen for Military Dirigibles.** The production of hydrogen for the airships of the war fleet is organized on an extensive scale in Germany. All military airship headquarters have their own hydrogen plants located in the vicinity so there are now twelve plants of the kind. At Altona near Hamburg, the *Zeppelin* station, the sea coast for airships who are in use with the navy, and the centers of Berlin and Frankfurt have each two hydrogen plants. Six of the stations lie along the west frontier. The new hangar constructed at Frankfurt especially for the airship *Zeppelin* type is 1,000 feet long and 100 feet high. It is a Zeppelin type, respectively, over 100 feet long. The *Zeppelin* type is a pipe line 27 miles long which is the first of its kind in Europe. It is a long pipe line, the delivery of gas per day is as much as 30,000 cubic feet. Average annual delivery is not so great as to prevent any leakage of gas. The pipe line ends in a gas holder of 200,000 cubic feet capacity and upon it are eighteen separate outlet taps for taking off gas for the airship's use. As these outlets are situated in the hangar itself, it is more convenient to fill out all the balloons of the airship at the same time.

The Gilbreth chronometer

At the December meeting of the American Society of Mechanical Engineers a remarkable development in scientific management was disclosed during the discussion of the report of the sub-committee on efficiency engineering. The article, the development consists in using the moving picture camera in recording the number of motions made and the time consumed for each—KISTON

One of the experimental packets.

## Micro-motion Study

A New Development in Efficiency Engineering

IN almost every work in efficiency engineering much space is devoted to what is called motion study. The number of motions made by a workman or a tool and the time occupied in performing these motions are accurately determined so far as possible. Hitherto the time element has been controlled by means of a stop watch in the hands of a trained observer—an easy task when it is considered that very often hundreds and even thousands of motions and operations must be studied and timed. The more expensive the study, the more likely are errors to creep in.

Part of a film, showing motions in assembling a braiding machine

and above all to eliminate the possibility of error. Mr. Frank B. Gilbreth, a very well known efficiency expert and one who has made a specialty of motion study, has invented an entirely new method, which consists in using a moving picture machine in connection with a special chronometer or clock, as it is termed in the parlance of scientific management.

At the December meeting of the American Society of Mechanical Engineers, Mr. John G. Aldrich of Providence and Mr. Robert Thurston Kent of New York revealed this new method in all its details. So interesting was the subject that it was discussed during an entire session of the Society on a Friday morning and during a supplementary session which lasted until late into the afternoon.

Mr. Gilbreth's special clock makes ten revolutions per minute. Its dial has one hundred divisions each of which, therefore, represents a time interval of one one-hundredth of a minute.

In studying the motions required to assemble a machine for example, the chronometer plays an important part as the object studied. It appears prominently in every one of the hundreds of pictures taken by the moving picture machine through the chronometer, an ordinary twelve-hour clock, which fixes the time of day, is placed so that in the moving picture film, complete information regarding the time study is included.

Every film reveals the successive positions of a workman in performing each minute operation of the task intended to him. The position of the chronometer pointer in successive films indicates the length of time between successive operations. These films are studied under a microscope, and a careful analysis of each operation is made to develop the standard time for each. The interval between the successive films in one study was a little under three one thousandths of a minute. Obviously such accurate time studies of minute and detailed operations can hardly be made by means of a stop watch. Fine as that method is, it can be made much finer. Chronometers can be used which make one revolution in one thirtieth of a minute, and the dial being divided into hundredths, it is possible to obtain time studies of greater refinement than at present appear necessary. Micro-motion

study is the name which has been given to this method of recording and studying minute motions or parts of motions. The film is far more than a record of time in the discussion before the American Society of Mechanical Engineers, it was pointed out that it will serve as an instruction card which may be enlarged and passed from workmen to workmen to teach the best methods of doing work. A film shows a workman not only what to do, but how to do it to the last detail, and, therefore, teaches him what printed instructions and books can never impart adequately. It also shows him the time which the most skilled workman can equal for a given piece of work, and which can be equaled if that workman's motions are imitated.

Any workman may, for a time, become an inexperienced efficiency engineer by "soldiering." But the camera cannot be deceived. The film records faithfully every movement made, and subsequent analysis and study reveals exactly how many of these movements were necessary and how many were purposely slow or useless. Hence by the elimination of the useless movements a most economical method of performing a given piece of work can be attained.

In the Providence works of which Mr. John G. Aldrich is vice-president and general manager, experiments in micro-motion study were made which involved the assembling of braiding machines. Originally the parts were assembled by bringing them to the job in boxes, from which they were taken by the worker, as he required them, and assembled at an ordinary work bench. In transferring the individual pieces to the growing machine many motions were unnecessarily made, all of which were disclosed by the moving picture machine. One result of this micro-motion study of assembling

order in which they are needed. A similar packet scheme was adopted for the parts of the leader.

First a horizontal packet was made up and the motion picture machine disclosed an irregularity and lack of rhythm in the movements of assembling, which seriously cut down the efficiency of the workman. Then a vertical packet was tried and a standard type of portable assembly bench was thereby indicated. After a few experiments a highly efficient arrangement was devised. The various parts were hung on pegs in the exact position that micro-motion study had revealed as the most economical of motions both in respect to time and length of travel. Thus the method permitted the development of the finally accepted method in a small fraction of the time and expense which would have been necessary under the conditions which existed before its invention.

Part of a film, showing motions made in using hammer.

### Sawdust Briquettes

A NEW industry may be successfully conducted with the planing mills—that of making out of the sawdust briquettes to be used for firing under the boilers, thus considerably decreasing the cost of the fuel to the mill owner. This is being very advantageously done in Germany. The sawdust is automatically gathered and conveyed to a place near the presses. From here it is carried over a heated belt-conveyor to a drying room. This is a cylindrical revolving drum about 2 feet in diameter and 20 feet long. In this drum the sawdust is partially dried, the pitch contained in the wood is softened, acting heretofore as a binder. From here the sawdust is conveyed over an incline to an after-dryer of the same shape as the first dryer, which forms a part of the press. Here it is submitted to a higher temperature to drive off all the moisture, and kept running forward toward the end of the after-dryer, by rotating paddles. At the end of this after-dryer, the sawdust falls through an opening into the trough of the press, which is a simple angle-lever press. The drive is of the usual shifting belt type, the fixed pulley acting as a flywheel. At the end of each pressing operation, which takes place about 34 times a minute, a briquette is made about 3 1/2 inches by 2 1/2 inches by 1 1/4 inch weighing between one half and three quarters of a pound. From the press the briquettes are carried by another belt-conveyor to a cooling room and are then ready for use. As the installation is very cheap, costing in Germany only \$54, it should recommend itself to the attention of sawmill owners, who could utilize to great advantage a heretofore mostly waste product of their mills.

The moving picture camera photographing a workman's motions. Note the clock.

braiding machines was the provision of a bench which brought the top of the completed machine at a convenient level for the workman, and the arrangement of the parts in an orderly manner in the building line. Although the number of motions was thus considerably reduced, there were still more than were absolutely necessary. Experience in other trades has shown that it is often desirable to group units composing a single assembly on a "pecker" and to arrange them in the

Books Forbids Crossing of Frontier in American or Abroad.—The Russian Czarist regime placed an order prohibiting foreign correspondents and aviators from crossing the Russian frontier for six months.

# Morning and Evening Stars for 1913

## Graphic Representation of the Planets and Their Movements During the Year

By Professor Frederic R. Honey, Trinity College

THE changes in the relative positions of the planets as exhibited every year in *Morning and Evening Stars* afford a pertinent illustration that in nature there are no such things as repetition, and while a supreme law prevails and controls every variation in planetary positions yet each planet yearly occupies a different place in the orbit and in relation to its fellows producing combinations which are always unique in planetary conditions. The presentation of *Morning and Evening Stars* thus includes an opportunity to locate each planet and incidentally to review annually the principal elements of the Solar System.

### The Sun.

The sun, whose mass is about seven hundred and fifty times the mass of the whole of all the planets and their satellites is a sphere whose diameter is 864,000 miles. It rotates on its axis in about twenty five days in the same direction as that of the revolution of the planets in their orbits. Some idea of the great magnitude of the sun may be obtained by comparing its diameter with that of the moon's orbit which is 477,700 miles. The sun is the only body in our system whose dimensions would be appreciable in the plot of the terrestrial planets in which it would be represented by a circle whose diameter is less than one hundredth of the radius of the earth's orbit. At a distance of nearly ninety three million miles, the sun's diameter subtends an angle of a little over  $\frac{1}{2}$  degree. At this distance the prominence which are visible during a total eclipse do not appear—the outline being that of a circle which may be represented to the observer by a disc whose inch in diameter at a distance of about nine feet from the eye.

### The Planets—Kepler's Laws.

The planets are conveniently divided into three groups—the Terrestrial planets (the asteroids, and the Major planets. Since the radius of Neptune's orbit is between seventy-seven and seventy-eight times that of Mercury it is impracticable to represent the orbits of all the planets in one plot. The orbits of the terrestrial planets are drawn to as large a scale as the limits of the page admit, and those of the major planets are necessarily plotted to a scale which is very much reduced. The great difference in the scales is evident by a comparison of the orbits of the earth and Mars in the two plots.

The plane of the ecliptic, which is the plane of the earth's orbit, is represented by this space which for convenience of reference may be placed in a horizontal position. A planet may be described as above or below this plane, but it should be understood that this description is simply to aid the imagination, since there is no such thing as horizontal and perpendicular, or above and below in stellar space.

The shapes of the orbits of the terrestrial and major planets from small angles with the plane of

the ecliptic. The intersection of the plane of a planet's orbit with the ecliptic is the line of nodes and the point A where the planet passes from the sphere below to that above the ecliptic is the ascending node. V is the descending node. Perihelion or point of nearest approach to the sun is at P.

### The Terrestrial Planets.

On account of the great eccentricity of the orbit the planet illustrates more vividly than any of the terrestrial or major planets the first two of Kepler's laws of

planetary motion. 1. The orbit of each planet is an ellipse with the sun at one focus. 2. The velocities of the orbit increase over equal areas in equal times. The center of Mercury's orbit is at B at a distance from the sun of a little over one fifth of the mean distance between the sun and Mercury and the area of the triangle with that part of the orbit between the positions at the dates August 2nd and August 8th with the sun as vertex is equal to the area of the triangle with the same vertex and a base equal to that part of the orbit between the dates October 1st and October 8th. The planet accomplishes its revolution in very nearly 88 days (87.97) and the positions are shown at intervals of two days. In order to avoid confusion the date is attached only for every eighth day. Mercury's orbit is inclined to the ecliptic at an angle of 7 degrees. The mean distance from the sun expressed in terms of the earth's mean distance is 0.3871. The period (88 days) 0.2408 and 0.1651 = 0.0757.

0.2408. Illustrating Kepler's third law. 1. The squares of the periods of any two planets are proportional to the cubes of their mean distances from the sun. The orbital velocity of the planet is subject to great variations. At perihelion it moves at the rate of 75 miles a second, at aphelion the velocity is reduced to 33 miles a second.

### VENUS

The eccentricity of the orbit is less than that of any of the terrestrial or major planets. Its linear measurement being so small that it is scarcely visible in the plot. As a consequence Venus moves in a very nearly circular orbit at an almost uniform velocity of 22.9 miles per second. The plane of the orbit is inclined at an angle of nearly 3.4 degrees and the planet's mean distance from the sun is equal to 0.723 times the earth's mean distance. The period of revolution is 224.7 days and the position of Venus is shown at intervals of four days. On August 14th the planet very nearly reaches the position of January 2nd. The distances between these positions is that traversed in seven times of a day.

### THE EARTH

The center of the earth's orbit is at a focus eccentricity  $e$  representing an ellipse over 15 million miles. Thus in January our planet approaches more than three million miles nearer the sun than in July. At a mean distance from the sun of 92,945,707 miles the earth performs its revolution in 365.25 days at a mean velocity of 18.5 miles per second. Its positions are shown at intervals of four days.

### MARS

The great eccentricity of the orbit here the distance at a distance from the sun equal to nearly one tenth of the mean distance of the planet. The plane of the orbit is inclined at an angle of 1.85 degrees. At a mean velocity of 15

ORBITAL MOVEMENTS OF THE MAJOR AND TERRESTRIAL PLANETS FOR 1913.

The Shuman solar power plant set up at Meadi, near Cairo, Egypt.

## An Egyptian Solar Power Plant

### Putting the Sun to Work

IN THE SCIENTIFIC AMERICAN of September 30th, 1911, we described and illustrated the solar power plant which Mr. Frank Shuman of Philadelphia designed for eventual use in Egypt. The plant was actually transported to Egypt and there set up but in slightly modified form.

It will be remembered that instead of employing lenses or mirrors as Edison did, to concentrate upon a small boiler the heat rays of the sun, Mr. Shuman utilized a heat absorber which may be likened to a greenhouse. In the Philadelphia plant a thin film of water flowed over the bottom of a trough inclined by two layers of glass between which was an airspace. Plane mirrors at each side of the trough reflected additional rays of the sun upon the water. The trough was carefully insulated. In this absorber the water was raised to a temperature very nearly that of the boiling point of water. To utilize the heat energy thus stored up, Mr. Shuman had to devise a special low pressure reciprocating steam engine. The heated water which is utilized was returned to the absorber after having performed its duty.

In the Egyptian plant Mr. Shuman used parabolics instead of plane mirrors, with better results. All told five absorbers and reflectors were installed at Meadi, a suburb of Cairo. Each reflector parabolic in form was 204 feet long and in its focus was the trough. Silvered glass mirrors lined the sides of the reflector and constantly faced the sun. The troughs of all five reflectors were rectangular in section 14 inches wide with sides only three inches apart. In order to increase the heat absorbing efficiency the troughs were painted black.

The glass plates and insulating material employed in the absorber of the Philadelphia plant have been discarded. The steam is collected at one end in a pipe four inches in diameter and the water flows in at the other end. Between the water and steam rods there is a drop of six inches in the entire length of 204 feet of the absorber. The engine presumably is the same as that which was used in Philadelphia. It works at somewhat below atmospheric pressure or at a pressure corresponding with a temperature of about 200 deg. Fahr. Connected with the engine is a condenser of the ordinary type and auxiliaries, such as may be found in many condensing plants. The vacuum to operate the condenser is obtained by starting by means of a gasoline-driven air pump. After the plant is in full operation the gasoline engine is cut out.

In order that the reflectors may be cleaned—an oper-

ation more or less frequently necessary because of the dust prevalent in Egypt—the mirror frames can be tilted and the mirrors washed with a hose.

In the Philadelphia plant the troughs were mounted on supports which elevated them some thirty inches above the ground and which permitted them to be inclined perpendicularly to the sun at the meridian. These adjustments of the installation were made about once in three weeks. In the Egyptian plant the reflectors were made to follow the sun automatically throughout the day by gearing them up with the main steam

troughs. For all that Mr. Shuman assures us, the site absorbers lasted long enough to prove that the plant might be eventually successful. He claims to have found that water can be pumped for less than one third of the price which would have to be paid if coal were burned. A set of steel troughs is now in course of construction, which will probably be installed in about four months. By welding the joints with the oxy acetylene flame he hopes that they will be absolutely indestructible.

Mr. Shuman states that the steam pipes are so long that the steam becomes highly superheated where it issues near the engine.

Up to date something like one hundred thousand dollars have been spent on these experiments.

### The Art of Primitive Man

ONE far-off ancestor of the stone age, the rude and primitive man of the quaternary epoch to whom the use of fire was unknown and whose arms consisted of a few roughly hewn pieces of flint, nevertheless appear to have had some rudimentary artistic ideas. In fact, sculptures dating from 200,000 years were shown at the last congress of prehistoric archaeology and anthropology, which recently held its fourteenth meeting at Geneva. This subject was treated by a French scientist, M. Dharvout, of Bethune, and he showed specimens of sculptured silex representing animal figures which were found in the alluvial strata of the quaternary epoch, among arms and instruments of the same period. M. Dharvout made an interesting communication to the congress about these first trials at sculpture which have yet been discovered. Natural stones were used which had some resemblance to animal figures, and these were afterward retouched so as to finish the work. One of the striking specimens is the head of a monkey, in which the features are very clearly seen, especially when viewed in profile, as the photographs show. We hope to be able to obtain views of these specimens in the near future.

Heads of other animals and birds are also among the most remarkable specimens. Authorities on prehistoric questions consider that the grates bearing these finds date from about 250,000 years.

A Mammoth Head.—What is believed to be the largest rudder ever made in two pieces, the top portion weighing 27 tons and the bottom portion 15 tons, has been built for the new Allan Line "Olympic," now under construction at Glasgow. The total height of the rudder is 26 feet 6 inches and the extreme width is 27 feet.

In the focus of five parabolic reflectors, each 204 feet long, a trough is placed through which water runs in a thin film

The mirrors are carried on arc-shaped frames which can be rocked so as to face the sun at all times.

outlet itself. This was accomplished by a pair of friction rollers controlled by a special regulator, the chief element of which was a thermostat.

Instead of twenty-six rows of absorbers the number used in the Philadelphia plant, five only were installed in Egypt, so placed that one could not shade the other. The Egyptian plant was started with six boilers or absorbers. A temperature so near the boiling point of zinc was reached that the troughs finally hung down limply like wet rags. Although hard solder was employed, it melted down at the top of the absorbing

## "The Whip" and Its Mechanism

A Ponderous Melodrama with Dogs, Horses, Automobiles and Trains that Move and are Wrecked

The exhaust machine and whistle is driven by a motor. One machine is used for the train and one for the automobile.

Back of the car, showing motors for driving false wheels, raising and rotating the panorama. Note the steam exhaust.

"THE DRURY LANE," with its maudlin melodrama, is a household word among all English-speaking people. The stage of this theater, with its huge electrically-driven bridges, lends itself to effects requiring ponderous machinery and accessories. One of the best plays ever put on at the famous London playhouse was "The Whip," which ran continuously for two years, delighting hundreds of thousands. This production has now been translated bodily to the Manhattan Opera House, New York. There are four acts and thirteen scenes in the play but we need concern ourselves only with two, which are interesting from a mechanical point of view. These are the famous rail road wreck and the horse race, both of which are now illustrated for the first time by authoritative photographs and drawings.

The entire play is written around "The Whip," a race horse of phenomenal speed, on which large sums of money are wagered. This forms the motive which leads to the perpetration of an atrocious crime. The race is supposed to be run at Newmarket for the "2,000 guineas" stake. This necessitates the transportation by rail of "The Whip," with her trainer and jockey, in a box car, such as we so often see attached to English local trains. One of the prettiest scenes is that where the race horse is led to the Falconhurst Station and loaded on the waiting box car. Presently you hear the sound of the whistle, the friction of revolving wheels and the exhaust of steam, and a regular English coach, with four compartments, comes slowly down the track and picks up the box car. The signal

to start is given the wheels revolve, the country flashes past. After a few minutes a tunnel is reached, and the audience can even see the bricks as the train rushes through it. This is the opportunity which the villain has been waiting for, the death of the mare must be accomplished at all hazards. He opens the door of his compartment and crawls along the running board

heard approaching at a rapid rate of speed. The cat near fails to stop in time and the locomotive strikes the box car, which is converted into kindling wood. There are many passengers on the express train killed and wounded. The steam and fire effect at the locomotive is very realistic.

Now, let us explain how it is accomplished. The coach is operated by about eighteen men, who control the various switches and force the car back and forth attend to the exhaust to the whistle and to the manipulation of the panorama. Only three men can be shown at the back of the coach, otherwise the machinery would be obscured. There is a set of false wheels in front which do not run on the track, but mask the actual wheels. An electric motor serves to operate them motion being transmitted from the rear of the coach to the false wheels by the aid of shafts. There is another motor which raises the small panorama at the back of the coach which serves to simulate the bricks in the tunnel. A third motor is for the purpose of driving this panorama widthwise. The electric lights in the coach go out for an instant when the panorama is raised. The effect of the exhaust steam from the locomotive is obtained by using a jet of steam illuminated from a spot light and working intermittently. A simple exhaust throttle valve controls this jet. It is started in hand and when the speed of the train is to be increased a motor is thrown in. The whistle is carried on the same framework and is blown at the time of starting and stopping. A simi-

(concluded on page 90)

The box car containing "The Whip" leaving Falconhurst Station

throws off the tall light on the box car and uncouples the car, leaving it standing on the track, while the train passes out of view of the passengers.

The heroine finally succeeds in reaching the tunnel by automobile just in time to release the horse and the jockey, the trainer having been detained by a misadventure in Madam Tussaud's "Chamber of Horrors." They make frantic efforts to flag the express, which is

The wreck at Newmarket Junction. The horse is saved, but the box car is destroyed. Note show path of steam pipes.

## Climbing a Magnetically Supported Chain

By Our Berlin Correspondent

**A**N interesting experiment was recently made at the works of one of the large German manufacturing firms with a series of their lifting magnets. A chain was secured to the ground at one end and carried up an iron ball at its free end and was raised to a vertical position by the approach of the lifting magnet suspended from a crane.

As seen from the accompanying photograph, the chain throughout its length remained in vertical position before the magnet. A grown-up workman climbed up the chain without disturbing its rigidity. The chain seemed to float in air. The magnetic pull on the ball was greater than the gravitation's pull on the man.

This remarkable experiment shows the enormous power of attraction exerted by industrial lifting magnets as used on an ever-increasing scale in iron and steel works for the transport of iron materials of every description. In no other field of metallurgy are the economical advantages of transport by electricity so conspicuous as in connection with the use of lifting magnets, which enable the operator to move the iron material at any point desired conveying it to any other point within the range controlled by the crane. Incidentally, it should be noted that the use of lifting magnets eliminates much of the risk of accidents formerly connected with manual transport and the use of hand operated cranes.

Cranes with lifting magnets are of course used on a large scale also in connection with the loading and unloading of railway wagons with all sorts of iron material.

## His Mattress a Life Raft

**A** DISTINGUISHED lieutenant of the U. S. Revenue Cutter Service recently hit upon the idea of making a life raft which may serve also as a mattress for use in bunks and beds on shipboard, as well as in houses and hotels along waterways where floods and overflows may take place suddenly and endanger the lives of the occupants. The mattress is constructed of resilient material provided with the usual ticking and surrounded with the usual ticking and substantially airtight casing. This is further provided with an outer waterproof envelope to act as a protecting sheath for the inner casing. In place of felt the inventor prefers to use a resilient filler which is in itself a water-repellent material, so as to prevent the mattress from becoming waterlogged. In case the cover becomes ruptured or torn. In order to prevent the mattress from sagging in the center or bending under the great horizontal stresses to which it may be subjected by the waves, a rigid marginal stiffening frame is provided. Lashings are also attached to each corner of the mattress, so that when it is used as a life raft they may be tied diagonally across the mattress to strengthen the frame and also to provide means for securing persons or articles to the float. In addition to this, loops and handholds are provided along the margin of the mattress. One of our photographs shows the mattress in use as a raft. In order to fairly test its efficiency, a mattress only 25 inches wide and of a size to fit the narrow transport steamboat bunk was punctured with seventeen holes and then heavily loaded with lead and floated in the water. It remained in the water for three days, without showing any tendency to sink. The accompanying photograph shows the appearance of the mattress after this treatment.

## The Edison Electric Safety Lamp

**O**N the evening of January 23rd, at the American Museum of Natural History, New York, the Rathbone Medal granted by the Allgemeine Electricitäts Gesellschaft, Berlin, for the best device or process in the electrical industry for safeguarding

industrial life and health will be awarded to Thomas A. Edison, for his safety miner's lamp. The desirability of using electric lamps in place of oil lamps, even those protected with a "Davy" wire screen, is strongly felt in these days. What is needed in mines is a positive light which does not depend upon the uncertain quantity of oxygen contained in the surrounding atmosphere, but is absolutely self-contained. Further, even a Davy

lamp is not perfectly safe if through careless handling it is broken.

Mr. Edison's miner's lamp is operated from a storage battery of large capacity and very light weight, which may readily be carried upon the back of the miner for the manner indicated in the accompanying engraving. The nickel-cadmium battery is particularly adapted for such work where it is liable to be roughly handled, and subjected to such treatment as would

put the ordinary lead storage battery out of commission in a short time. The battery is completely sealed and locked so that the miner cannot tamper with it, and it has only one reliable connection for escape of hydrogen gas, when it is being charged. There is no danger of escape of the electrolyte even if the cell is inverted, because the outlet for the gas is at one end of the steel tube which extends downward from the top of the container to within a half inch of the top of the electrolyte, and is so formed as to preclude the escape of the solution even when the cell is vertically shaken. The gas that pass off do not carry with them any substance to corrode the steel parts used in the construction of the lamp or the case of the battery or the clothing of the miner. No injury is done if the cell is overcharged, and no harm comes to the plates if left semi-charged or discharged for an indefinite period. The cell may even be charged backward without serious consequences, although of course the battery will give no service unless charged in the proper direction. The only attention required aside from charging the battery is to replenish it with distilled water from time to time and renew the electrolyte after about nine or ten months of continuous daily service.

The flexible cord connector between the battery and the lamp is provided with a terminal which when shoved into the socket of the battery case becomes locked therein and cannot be removed until the padlock on the side of the case has been removed and the lock bar withdrawn. And so it is impossible for the miner to cause a spark by disconnecting his wires in the mine. To protect the conductor it is incased in flexible steel armor so as to prevent a sharp bend. A tungsten lamp is used with a parabolic reflector and a heavy lens to distribute the light over the proper area, and the lamp is provided with a hook that may be fitted to the regulation miner's cap. This lamp is the result of several years of persistent work on the part of Thomas A. Edison.

## The Life of London

**F**ROM the London County Council's statistical abstract for 1911 12 some conception may be formed of the activities of that portion of Greater London which is confined to the county of London. It should be understood that Greater London, with an approximate population of 7,200,000, overlaps the county of London, and passes into the counties of Middlesex, Hertfordshire, Essex and Surrey. Some of the figures given in the London County Council's abstract appear below.

Population, 4,023,061; Gents, 850,958; 999; weddings a year, 40,301; births, 115,780; deaths, 61,500; deaths by accident, 1,540; fires, 3,205; marriages, 40,060; births, 17,535; soldiers, 10,058; postal employees, 40,990; druggists, 1,395; motor cars, 8,818; postoffices, 1,051; letters delivered, 806,900,000; post-cards, 150,000; telegrams, 65,000,000.

The imports into London constitute 88.8 per cent of the total imports into the United Kingdom, and more than half the income tax on salaries is paid by London.

## Motor Street Sprinklers in Europe

**R**EARING the use of special power wagon outfits for municipal service, we may mention that the city of Paris is now employing a number of motorized sprinklers and extinguishers, these being made by several different firms. It is stated that the city of Berlin is to purchase 20 combined sprinklers and extinguishers, representing the cost of 40,000 marks. As yet the first department which has motorized extinguishers and 50 motorized sprinklers, and will have 100 motorized extinguishers and 100 motorized sprinklers. The motorized extinguishers are of the type known as "motorized extinguishers" and the motorized sprinklers are of the type known as "motorized sprinklers".

Climbing a magnetically supported chain.

How the electric safety lamp is worn by a miner.

The safety lamp and battery with battery lock bar removed.

Using the mattress as a life raft.

Mattress after floating for 24 days.

**R**ADERS are invited to contribute to this department photographs of novel and curious objects, unique occurrences, and stupendous coincidences. Such as are available will be paid for promptly.

### Motor-pumped Street Sprinkler

**I**N order to provide a wider distribution of water from a street sprinkler a machine has been built which is propelled by a gasoline engine, and which has a double-acting water pump driven by the motor. With this combination the water may be spread over streets 70 to 80 feet wide on a single run. The operation of the pump may be governed to control the area to be sprinkled and to insure a uniform distribution of water. One of the objections to the usual type of horse-drawn sprinklers is the fact that the nozzles are placed at the rear of the vehicle, and do not prevent the raising of dust by the wheels and horses. In order that the motor truck may not cause the very evil it is designed to cure, the spray nozzles are placed about a foot in advance and on either side of the motor hood. Thus the street is wet down in advance of the wheels and no dust is raised. The sprinkler shown in the engraving has a tank 4½ feet in diameter with a capacity of 1400 gallons which is mounted in a cradle and guyed with cross braces upon a 4½ ton chassis. A curious phenomenon may be seen in the illustration. The pollution of the double action pump may be clearly observed in the spray of water thrown off from the nozzles.

Note the spraying spray caused by the pulsations of the pump

Raising the statue of "Electricity" at the Union Station, Washington

Legs of Max Unger's gigantic Frithof monument

The "noodle cup" fountain.

"Magnet BHP" moving automobile tire.

Although "Bang Ball" had a lump of mud containing the capsule in which it lives, breathing air during a drought.

York that has shattered all popular conceptions of what a fish ought to be as it possesses the surprising power of living six months, or possibly a year out of water. Indeed of a miniature aquarium or some sort of a box filled with the customary amount of water for its long sea voyage of thousands of miles the lung fish was transported in a block of dry earth which had only a funnel like opening to admit air for the fish's breathing. This pit led into a tube of hardened slime which went into the fish's mouth and conducted the air directly into the lung of the fish. The lung fish is a very old creature by means of gills when in water but with a lung during the summer drought inhaling and exhaling air as though it were a land living animal. The fish came from the Canadian region of Africa coiled up in a kind of cocoon or capsule deeply sunken in a large clod of earth. To liberate the fish it was necessary to cut the hard earth away carefully from the paper cocoon. Then the cocoon was placed in tepid water, and the shell which was formed by a mucous secretion on the surface of the fish's body. Within a few minutes the cocoon showed movements and shortly the fish emerged from it. The lung fish has been placed on exhibition in an aquarium in the Hall of Poised Fishes. Prof. Bashford Dean states that it had been placed there because it is at home scientifically speaking among fishes which lived millions of years ago and whose race is almost extinct. A more complete description of this curious creature may be found in the current Supplement.

### A Gigantic Monument

**T**HE German Emperor's passion for monuments is expressed in a series of rather fantastic statues which have been mounted in the Regency of Berlin to the intense amusement and disgust of all the comic weeklies in Germany. It is responsible for Max Unger's Frithof monument. Next summer this colossal piece of work the mere legs of which are presented in the annexed illustration from *Kosmos*. A statue will be unveiled in Norway to commemorate the twenty-fifth visit of the Emperor to that favored Scandinavian country. Naturally the monument is a gift from the Emperor and he himself will attend to the unveiling. The imposing legs hereafter reproduced attain the majestic height of 23 feet. It was almost without saying that the monument had to be made in small pieces. The statue will be erected on a peninsula opposite Balthia where according to tradition the graves of Ingoborg and Frithof are to be found.

### Saving Tires With a Magnet

**H**E doesn't look like a very important part of a big automobile, but a device of great invention this tall broad shouldered stooped and somewhat grizzled man who may be seen rain or shine summer or winter walking slowly about the plant eyes almost constantly cast earthward but he is an important item in the modern method of factory operation. Though his wage is that of the average workman, Magnet Hill, as the grizzled man is known, is worth a good deal to the company by which he is employed. Hill gets his nickname from the fact that his tools consist solely of one tin bucket of the 10 or 12-quart variety and a big steel magnet strapped to the end of a short handle to allow for case in operation. And his work is very important in that though it looks simple to the passerby for it is Hill's duty to save and make tire life by removing from the roadway every nail and bit of iron or steel that might cause a puncture. When it is known that 40,000 cars are run over this course and that from the plan, where they are tested and scores of visitors cars office machines and delivery trucks use the thoroughfare daily the value of Magnet Hill is at once apparent.

### New Sanitary Drinking Fountain

**A**N FWF type of sanitary drinking fountain has been erected in Lafayette Square Washington D. C. This square is immediately north of the Executive Mansion and almost in the shadow of the Cosmos Club of Scientists and the noted aristocratic St. John's Church which most visitors to Washington remember. The design of the fountain is rather ornamental, but unobtrusive. The fountain has a large basin into which the overflow from the noodle cups discharges. The noodle cups are at the outer ends of flexible tubes whose inner ends connect with the water supply and the water flows up freely through to opening in the center of a dome-like plate rising almost to the top of the cup, so the user can drink without touching the susceptible parts of the cup, and of which the water constantly flows in a bubbling stream. The cups are charged by individual valves to an upper portion of the fountain, as they come fall outside the basin which placed by the fountain. After the cup is placed in use the water flows from the basin into the cup, and the water is then used for drinking.

The fountain is a new type of fountain, and has been erected in Lafayette Square Washington D. C. This square is immediately north of the Executive Mansion and almost in the shadow of the Cosmos Club of Scientists and the noted aristocratic St. John's Church which most visitors to Washington remember. profitable  
things you  
can do with  
this wonderful  
machine

## THE MULTIGRAPH

*Produces real printing and form-typewriting, rapidly, economically, privately, in your own establishment.*

ORIGINALLY the Multigraph was simply the best means for the rapid production of form-typewriting, a whole sheet at a time instead of a character at a time. Later it was discovered that the accurate contact produced by the Multigraph took the place of the heavy pressure exerted by the ordinary printing-press, so we perfected a simple but effective printing-ink attachment.

Now the Multigraph does real printing—printer's printing—using curved electrotypes that reproduce any size or style of type desired, as well as cuts, borders and ornaments; using your choice of ninety sizes and styles of hand-set type; or using the machine's self-contained equipment of typewriter or Gothic type, set semi-automatically.

### How to Get More Business

With the Multigraph you can carry on a complete advertising-campaign by mail, or conduct an effective follow-up for your magazine and trade-paper advertising—by typewritten form-letters, and printed literature such as booklets, folders, circulars, etc.

And by Multigraphed letters or a house-organ you can put ginger into your sales-force, increasing sales.

### How to Aid Administration

Most of the office and factory-forms that are necessary to the conduct of a systematic business can be produced at a saving on the Multigraph.

Many will, of course, be printed from electrotypes, but many others can be printed from the machine's self-contained type, at little cost beyond the expense of the paper.

### How to Save Expense

In all the foregoing applications, the Multigraph prints at a saving of from 25% to 75%. You could extend that saving to another field by printing your office-stationery on the Multigraph—letter-heads, bill-heads, statements, envelopes, and the like.

### The Multigraph System

The basic Multigraph does form-typewriting only. Add the signature-device, and it produces letter and signature at one impression. Add the printing-ink attachment, and it becomes a complete printing-machine.

The Multigraph Printer is the

printing end of the basic machine divorced from the type-setting mechanism. The Multigraph Compositype is the type-setting end without the printing end.

The Multigraph Letter-Folder folds letters at the rate of 4,800 an hour—all customary folds.

The Markoe Electric Envelope-Sealer seals envelopes—6,000 to 10,000 an hour.

### Multigraph Service to Users

This deals with the brain-work that the machine translates into printing and typewriting.

Without cost to Multigraph users, it aids them with their problems in advertising, selling and business-system.

You can't buy a Multigraph unless you need it.

Begin your investigation today. Get in touch with our nearest branch office or write us direct, on your business stationery, for interesting information. Use the coupon.

### What Uses Are You Most Interested In?

Check them in this list and send it with your return for information, money, or new type sets, or other information. The information is being sent to you.

Individual"*

## Cold Weather and Bad Roads

A combination you will meet often during the next two months. It will test your motor to the limit. Is your motor ready for the test?

During cold weather the question of lubrication is vital. Many oils congeal, become "lumpy." You start your motor. For half an hour or so, until the oil becomes thoroughly heated, the motor gets practically no lubrication. That plays havoc with the cylinder walls.

Texaco Motor Oil shows a zero cold test. It will not congeal at that temperature. During the coldest weather it will lubricate perfectly.

When you use Texaco Motor Oil your motor delivers maximum power with minimum consumption. Tests of Texaco Motor Oil conducted during runs of 20,000 miles and more have shown an *extra savings* of carbon accumulation.

Texaco Motor Oil should be your oil this winter. It is for sale in 1 and 5 gallon cans at most good garages and supply shops.

## Water Supply

¶ To meet the pressing demands of five million inhabitants, New York has been obliged to undertake the most stupendous aqueduct system in the history of the world.

¶ Hampered by its situation on a narrow strip of land that intrudes between New Jersey and Connecticut, this, the second largest city in the world, has had to look to the north, and the north only, for its supply of water.

¶ In the heart of the Catskills an entire valley has been swept bare and converted into a lake 40 miles in circumference.

¶ From this reservoir runs an enormous conduit that dips into valleys and under rivers, pierces mountains and bores through solid rock, 1100 feet beneath the Hudson River, to the Croton Reservoir.

¶ Thence down through the heart of the city, so far below the surface that the busy people above give no thought to the daily firing of tons of dynamite, the conduit is being gnawed through solid rock.

¶ Finally a pipe line extension will pass under the waters of the bay to Staten Island, 127 miles from the source in the Catskills.

¶ The whole marvellous story will be told in the *Scientific American* of March 1st.

¶ Price 15c at all newsstands.

## The Pen That Satisfies Millions

Waterman's  
(Ideal)  
Fountain Pen

### PROOF—

ask those who use them, then ask for the pen by name and satisfy yourself.

There is a very simple reason why Waterman's Ideal is the world's most efficient pen. It is only because it is the most scientific and most carefully made pen in every detail. And the making of such a pen is all detail. No part can be slighted, from the selection and vulcanizing of the special rubber, the hand-turned and fitted parts, to the modeling of the famous "spoon feed." Then the sensitive gold pens are of themselves a wonderful work, hand-beaten into perfect writing points of every degree and delicately tipped with costly iridium for permanence. The efficiency of the workmen who make Waterman's Ideals makes the efficiency of the pen in actual use. Hundreds of styles and sizes to choose from; pens exchangeable until you are suited for efficiency and appearance.

Ask for the pen by name—Waterman's Ideal

Sold by leading dealers throughout the world

L. E. Waterman Company 173 Broadway, New York

## Better Train Service for Rural Communities

The applications of the General Electric Company's motors to extend irrigation, reduce farm labor, and provide modern lighting and other conveniences in the home are well known to the readers of these pages.

Now electricity is benefitting the agricultural districts in a new way, for the steam roads all over the country are adopting the Gas Electric Motor Car to provide greater economies and produce better traveling facilities on their branch lines

This car is self propelled, and is a unique combination of the best features of the automobile, the trolley car and its predecessor—the steam train

Like the automobile, its source of power is located in a gasoline engine placed in the cab near the operator, who can speed up, slow down or entirely stop the power at will. Unlike the automobile, however, the power is not transmitted by gears which would subject the machine to serious mechanical shocks and vibrations, but the engine is connected to an electric generator which feeds electric current to electric motors under the car

Like the trolley car, the propulsion is accomplished by motors and control apparatus similar to that furnished by the General Electric Company to electric roads all over the country during the past twenty years

Like the fast trolley car also, this car glides over the country, providing cool breezes for the passengers without dirt, dust or smoke in the summer, and with entirely closed and comfortable accommodations comparable with Pullman Car service in the winter

Like the steam train, this car provides ample accommodations for the baggage, smoking and passenger traffic of the average branch line

What this new train means to Rural Communities can best be judged by its phenomenal popularity both with the Railway companies and the traveling public. Twenty progressive steam roads have already placed over fifty of these cars in daily operation throughout the United States. In every case the results show that the quick and attractive service makes it easier for people to travel and conduct their business or seek pleasure, and that inter-relations between rural communities are greatly stimulated by the application of this modern invention

Another advantage to the rural community comes through the fact that the highly economic operation of these cars makes it possible for the railroad company to insert more frequent local service between main line trains, thus materially increasing the efficiency of travel in rural communities.

When this car is placed in service in your locality you will undoubtedly show your appreciation by extended patronage of this modern method of branch line operation

In the meantime, the manufacturing facilities and extensive experience of the company, which makes everything electrical, from the smallest size of Edison Mazda lamp to the Gas Electric Motor Car, are available for immediate application to your business, or in your home.

## The Rock-removing Machinery of the Sues Canal

By Jacques Boyer

THE Sues Canal traverses a diversified country. Near Port Said it passes through argillaceous sand and a few large beds of more or less compact clay. The bed of Lake Tinnah consists of a hard conglomerate of sand and limestone, between Lake Tinnah and the Bitter Lakes occur loose mud, mixed with clay, gravel and gypsum, and overlain by a layer of salt and other deposits left by ancient evaporation. Finally, compact clay, marl, and sandy conglomerates alternate until the Red Sea is reached. No rock has yet been found except in the southern part of the canal between kilometer 85 and 86. Here the outcrop of the rock is almost horizontal. It occupies an area of 300,000 square meters (3,520,000 square feet) in the bed of the canal. The rocks include limestone of greater or less hardness, calcareous and siliceous conglomerates generally containing shales, red calcareous tuffs, gypsum and alabaster. In general, the rock is of medium hardness, except in certain deposits of compact limestone and sandstone.

In the construction of the Sues canal, the rocky portions were removed before the water was admitted. In 1864, when the company undertook the work of widening and deepening the canal, it became necessary to devise means of removing rock under water. The hardest rocks were shattered by submarine mines, and the softer ones were removed by apparatus composed of a battery of 10 steel rams, weighing 3.5 tons each, which were raised and let fall on the rock in the manner of pile drivers. These same were placed on a floating bucket dredge which removed the rock as it was broken.

Experience soon showed that the efficiency would be increased by separating the rock breakers from the dredge and placing them on special floats. Although this arrangement produced an appreciable improvement it still gave only a mediocre result because of the insufficiency in the weight of the breakers. From fourteen to sixteen blows per square meter were required to break up rock of medium hardness to a depth of  $\frac{1}{4}$  meter (20 inches).

In 1867, when it was decided to increase the depth of the canal to 9.5 meters (31 feet), the engineers of the company studied the question more thoroughly. They found that for the removal of rock under water, the method described above is more economical than drilling and blasting. Furthermore, the employment of explosives presents certain obstacles to the navigation of the canal. After each blast, for example, it is necessary to send down divers in order to make sure that the channel is not blocked by the shattered rock. The blasting method cannot be carried out so regularly as a plan as the other, and it also involves the removal of an excessive quantity of rock in order to obtain the desired profile with certainty. A few years ago, therefore, the engineers decided to adopt a rock breaking apparatus provided with two spade-shaped rams of cast steel, 13.5 meters (44.3 feet) long and weighing 13 tons each. These rams terminate below in replaceable points of very hard steel. The two rams are placed a yard apart and are raised by powerful steam winches which operate almost instantaneously through very flexible steel cables permanently attached to the tops of the rams. By means of this arrangement it is possible to hold the rams very rapidly and to regulate without difficulty the height of fall which ordinarily ranges from 5 to 10 feet. The two winches may be coupled in order to exert an exceptional effort upon a single ram which has become fixed in the rock.

The apparatus is mounted on a float 30.5 meters (100 feet) long 10.37 meters (34½ feet) wide and 2.44 meters (8 feet) deep, made entirely of steels and iron. The falling rams are guided by a frame of special construction which also carries the pulleys over which the cables run. The float is moved forward, backward and in any direction rapidly by means of a steam winch.

The apparatus was put into service in 1902, and since a few improvements in detail have been made, it has operated perfectly and broken all kinds of rocks without difficulty. In 1908 a second apparatus was installed having two rams weighing 14 or 15 tons each and 15 meters (49 feet) long which operate to a depth of 12 or 11 meters (about 41 feet). As a rule, 132 blows are delivered in each working hour. The mean thickness of the layer of rock shattered is 0.8 meter (2½ feet). In these conditions the number of blows required to break a cubic meter of rock varies from one to forty according to the character of the rock. The average is about seven blows per cubic meter. The output thus varies from 13 to 4 cubic meters (17.2 to 4.1 cubic yards) per hour with a mean value of 10 cubic meters (24.5 cubic yards) per hour.

This apparatus was put into service in 1902, and since a few improvements in detail have been made, it has operated perfectly and broken all kinds of rocks without difficulty. In 1908 a second apparatus was installed having two rams weighing 14 or 15 tons each and 15 meters (49 feet) long which operate to a depth of 12 or 11 meters (about 41 feet). As a rule, 132 blows are delivered in each working hour. The mean thickness of the layer of rock shattered is 0.8 meter (2½ feet). In these conditions the number of blows required to break a cubic meter of rock varies from one to forty according to the character of the rock. The average is about seven blows per cubic meter. The output thus varies from 13 to 4 cubic meters (17.2 to 4.1 cubic yards) per hour with a mean value of 10 cubic meters (24.5 cubic yards) per hour.

## Largest Embankment in Germany

AFTER eight years' strenuous work the Mauer embankment has been completed. This, the largest engineering monument of Milleda, and at the same time the biggest embankment in Germany is situated in the Hober Valley between Hlitzberg and Lahn, at a widening of the river where the Rober describes a strong inflection.

The masonry dam has been erected on a rocky soil at about 60 feet deep. It is 395½ feet in height and at the bottom of the river 164 feet in width and withstands a pressure of 440,000 tons. The masonry on the side turned toward the water is provided with a concrete casing reaching down to the ground, to prevent any water from penetrating into its interior.

The interior of the wall comprises shafts and galleries. It is at the surface 915½ feet in length and 24 feet in width, and contains about 3,700,000 square yards of masonry. Being so exceptionally small, the dam will be it is fairly heavy, but the most dangerous of Milleda rivers.

Upward of the masonry dam an artificial lake 50 miles in length will be formed. The embankment controlling a precipitation area of 303½ square miles. The artificial lake will be 600 acres in area and 15½ feet in maximum depth.

This embankment will be utilized on a large scale for supplying power to an adjacent district of Milleda. The huge power house stands close to the outside of the embankment wall and comprises four turbines each of 1,800 horse-power. As, however, this power house is connected with that of the Quade Valley embankment near Marbach a total of 10,700 horse-power will be available which suffices to supply the whole district of Milleda with electricity for lighting and power purposes.

The embankment was inaugurated on the 10th of November in the presence of the Emperor.

## Some Facts About Granite

GRANITE is two and two thirds times as heavy as water. Its specific gravity is 2.652. A cubic yard of granite weighs exactly three quarters of a ton. The strength of granite is tremendous, although the different granites vary greatly. Poor granites will withstand a pressure of 1,000 pounds to the square inch. Fine-grained granite will withstand 30,000 pounds, but certain Wisconsin granites have withstood a crushing pressure of 44,073 pounds to the square inch—22 tons weight resting on a tiny cube of stone not much larger than a lump of sugar.

## A Fatal Blunder

By routing the bills to committee (which passed through the Panama Canal Congress) we dealt a death blow to American domestic shipping. Everyone who has studied the problem of the decades of our Merchant Marine understands that it is due to certain economic conditions over which we have no control. It costs so much more to build American ships than it does to build foreign ships. Successful competition with foreign ships in the deep-sea carrying trade is out of the question. That is a fact which no one disputes. Also it cannot be disputed that if we are to regain our former position as a leading maritime nation some form of government aid and subsidies is necessary. All that we will suffer without such subsidies are increased per cent duties of what not is the case with the foreign ships. The shipping aid money is forthcoming, at least in the early stages of the rebuilding of our Merchant Marine.

Unfortunately, and thanks to the persistent misrepresentations of the stump orator and the yellow journal, there is a country wide though unwarranted distrust of any proposed legislation which involves the principle of Government aid. The idea has been widely disseminated and too widely believed that Government aid represents nothing more nor less than the transfer of funds from the public treasury to the private purse of individuals and corporations.

Now the fatality of these matters of omission of a ton toll lies in this that to count these tolls to the already prosperous and highly protected coastwise shipping companies is to do exactly what the pilot price has said would be done in every measure that contemplated Government assistance to shipping. To omit the toll will be to make a free gift of \$120 a ton to shipping companies which are already flourishing under the protection of a rigid monopoly.

So then the first attempt of Congress to give assistance to shipping will be a glaring example of that verbiage of the excellent principle of Federal aid, which the country thanks to misrepresentation is so greatly afraid. With this preposterous act before their eyes it is certain that the people of the United States will become more firmly settled than ever in their unfortunate prejudice against any attempt however common-sensical on the part of the Government to assist the shipping industry of the country. Moreover, it is only has Congress again misadventure where it is needed but it has killed for a long time to come any hope of assistance being given where it is needed.

### The Complete Eradication of Typhoid

**A** MEDICAL contemporary has asked us to say something on the subject of typhoid eradication by immunization and we gladly present the salient facts of this very vital subject.

One of the most important steps in the march of medical science has been the recent successful work in the prevention of typhoid fever by the use of typhoid vaccine. It has been demonstrated that inoculation will enable an individual or whole populations of soldiers for that matter to live in typhoid infected districts with complete immunity. It is not yet demonstrated just how long immunity will last but it is known that protection is assured for at least one year. Typhoid immunization is harmless and in most cases causes no incoveniences.

Now the hope of the complete eradication of typhoid fever lies in the fact that the typhoid organism does not remain alive for any great length of time in water or the soil, two of the principal sources of the spread of the disease. Repeated investigation has shown that the typhoid bacillus will remain alive in natural water only for a comparatively short time; furthermore there is no evidence that the germ will live in soil longer than in natural water. Hence for the purpose of preventing contamination of the soil or of some other water supply, there must be added, at comparatively short intervals, fresh typhoid bacilli from a case of typhoid fever or from a typhoid carrier.

Now here are two facts of supreme importance for the typhoid germ: 'I will not survive more than a few months when exposed to the elements during warm weather as stated by the *Bacterial Therapist*, and if immunized individuals cannot contract the disease for a year or more.' It follows that by carrying out systematic immunization during the winter months, there would be so few typhoid cases the following summer that the disease would be practically eradicated.

If a general typhoid immunization were carried out by the concerted action of the health authorities of the various States for a few years, there is every reason to suppose that the terrible scourge of typhoid would be swept out of the country. The State laboratories would furnish the vaccine at comparatively little expense. Would the public submit to the practice of general immunization? Thanks to the present day widespread knowledge on this general subject, and the public familiarity with the results obtained in controlling other diseases, we believe it would.

Is not general immunization well worth a trial?

### Some of the Absurdities of the Proposed Compulsory License Legislation.

[illegible]

How can the committee reconcile such a proposal with its professed abhorrence of anything that may ignore and override the jurisdiction of the State courts? Such a scheme of compulsory license will diminish the inventor's market value, may bring ruin to the inventor, will crush his weak rivals, impede every patent owner in developing and introducing his invention, retard the jointing of inventions and discourage the large scale inventions and industrial experimentalations on which civilization depends for solving the problems of a better world.

[illegible]

and that all or part of the licensee's work shall be done on the machine, if he attempts to limit the licensee's use of the patented machine to a certain territory, or to a certain class of persons, or to a certain number of persons, or to a certain number of machines, so that he may be free to license to others the exclusive use of his patented machine on other classes of goods or character of work, if the quality of his patented inventions is used to induce customers to purchase his patented machine, for all their needs, if he agrees with a retailer in a town to sell his patented goods to no one else in the same town or to sell to other retailers only on less favorable terms, in consideration of which the retailer shall push the sale of his patented machine, or if he grants the exclusive invention to a licensee who, for instance, makes steam engines of 1000 horse-power where he charges a rate of royalty different from that charged a licensee making steam engines of less than 1000-horse-power, or if he grants the exclusive right to make steam engines at a retail price then that at which he sells elsewhere

ANY of these transactions, which good morals and honorable business practices to-day and from time immemorial have always sanctioned, is shewn by the Bill to constitute proof of the violation of the Sherman Anti-Trust Act. The fact that the transactions might reasonably be shown to have the tendency to restrain trade, cannot serve as a misleadly potent overture, for the law is not to be evaded by the use of such devices. It is not to be deemed to have been or to be unreasonable, and so to be a violation of the provisions of said act (i. e., the Sherman Anti-Trust Act) as to any one quality of these transactions. The penalty which the patent owner may suffer for slandering in the manner indicated is for forfeiture of his patents, a fine of \$50,000 and a years imprisonment, and a payment of three-fold damages and the costs of suit and attorneys' fees to anyone who comes in within three years thereafter and proves any

### Machinery on the Farm

**M**ENTION farm machinery to the average man and immediately he sees in his mind's eye a picture of lugulent harvesters, rowers, and binders. Perhaps, too, he may think of the tractor outfit to which so much space has lately been given in the popular press. But he is not likely to think of the horse-drawn machine. And only if he be a technically informed man is it likely that he will think at all of the stationary engine and its agricultural possibilities, although it may be confidently asserted that it plays an even bigger part in transferring from flesh and blood to iron and steel the energy of the sun and the land's own sustaining crops. On many American farms, the little stationary engine is the most valuable piece of machinery to be found that varies in size from one and two-horsepower to forty and sixty horse-power, and that are used for almost every imaginable purpose.

It is difficult to estimate with any degree of certainty how many accurate statistics are available to show the actual number of engines in use, but the number must be in the millions. For example, in 1912, the number of engines in use was 100,000. For example, in 1912, the number of engines in use was 100,000. For example, in 1912, the number of engines in use was 100,000. For example, in 1912, the number of engines in use was 100,000.

It is safe to assume that there are about two million gasoline and oil engines on our farms at the present time—probably a conservative estimate. The number is being added to at the rate of about 500,000 annually. The average size of these engines is about seven horse power.

Every one of the 6,361,000 farms in the United States needs one engine at least, and many of them need two or three engines. Even under present conditions profitable use can be made of from thirty to forty million gas engine horse-power on the farms of this country. Surely here is an opportunity ready to be grasped by the enterprising manufacturer.

## Engineering

**Railway Construction in 1912.**—During the past year there was added to the railroads of this country less than 3,000 miles of new line, according to statistics compiled by *Railway Age Gazette*. This is 845 miles less than the average for the past sixteen years. On the other hand, the total mileage of new line commenced but not completed, is greater than it has been for five years past. Our steam railroad system is fairly complete, and it is natural to look for a decrease in new construction as the years go by.

**The Artesian Wells of Australia.**—The artesian well is one of the most important sources of water supply in Australia—a continent which is by no means lavishly supplied with the snow- and glacier-fed rivers which are so abundant in this country. A government report states that in 1911, in the State of Queensland alone, there existed 785 artesian wells, whose total depth aggregated 324 miles. Of these, 113 were over 3,000 feet deep, and one of them had earned, to a depth of 5,045 feet. Two of these boreholes, alone, gave a combined output of nearly 10,000,000 gallons daily.

**Efficiency of an Alloy Spring.**—One of the most important developments in metallurgy of recent years is the alloys which have been obtained with the various new steels—manganese, automatic, nickel, and nickel-steel. A new alloy of these metals, which contained 36½ per cent between centers and had a number of 15 inches. The spring was deflected under a load of 1,500 pounds to a straight line and then under a load of 5,000 pounds it was deflected 15 inches. Finally, pressure was applied until the spring was flattened down to practically a circle, without showing any sign of fracture.

**Post-proceeding Gas.**—(Child B. F. Haanel of the Fuel Testing Division of the Department of Mines, Ottawa, has reported that the post-proceeding gas-power plant has proved its reliability, its operation may be continued for a week or longer without shutting down for clearing or overhaul. A test plant has been run for 140 hours continuously, and the report states that in regular service it should not prove necessary to clean the pistons more than once in several months. The output of the producer is uniform, fire can be cleaned without interference with the engine, and any operator of intelligence can run the plant.

**Four-gun Turbines.**—According to the Paris correspondent of *The New York Times*, the French battleships *Arcturion* and *Asper* to be laid down in 1913 will carry twelve 13-inch guns in three four-gun turbines. Are not the French putting too many guns in one bow? One successful penetration by a high explosive shell might put four guns out of action at once. Against this it to be considered the use of fire and the consequent reduction in weight both in mount and armor. Our own three-gun mount (indeed we understand, a combined one for all guns and the three guns will be given the same training and elevation under the hand of one man.

**Important Railroad Electrification.**—The Secretary of the Interior may be premature in his belief that the electrification of all the transcontinental railways is at hand, but he is certainly justified in attaching great importance to the grant by the Government of permission for the Great Falls Power Company of Montana to transmit over the public domain the necessary power to electrify 450 miles of track of the main line of the Chicago, Milwaukee and Puget Sound Railway in Montana and Idaho. In respect of the length of track covered, this is by far the most important application of electric traction so far made to a steam railroad.

**A Notable Railway Bridge.**—In this age of notable construction, work which only a few years ago would have commanded world-wide attention, now is apt to attract not much more than local interest and comment. A case in point is the handsome railroad bridge, of the cantilever type, which has been built by the Pittsburgh and Lake Erie Railroad Company over the Ohio River, at a point about twenty-five miles below Pittsburgh. The total length of the bridge between main piers is 1,814 feet. The main cantilever structure, which measures 1,400 feet between centers of end piers, consists of a 370-foot end span, two 320-foot anchor arm spans, and a main span of the great length of 700 feet, which is made up of two 242-foot spans and a 285-foot suspended center span.

**Twenty-five Knot Battleships.**—The proximity with which the new 25,000-ton battleships for the British Navy are credited with a speeded speed of 25 knots, raises the question whether the Admiralty has determined to merge the battleship and the battle-cruiser into one—a logical, and as it seems to us, a very sensible decision. Water-tube boilers, superheated steam, and steam turbines have combined to render possible battleship speeds which could not have been dreamed of a few years ago. Our Navy Department has never favored the battle-cruiser, believing that our limited appropriations should be put into the first fighting line exclusively. Granted even the latest developments in naval construction, but if she builds 25-knot battleships will the rest of the power follow such a radical change?

## Science

**The Diving Rod Problem.**—We learn from Count v. Klenowstrom that a Society for the Elimination of the Problem of the Diving Rod has recently been formed in Germany. The society counts among its members many men of prominence in the engineering and scientific world, and its object is to secure a serious scientific effort to shed light on a much debated problem.

**Storm Signals of the World.**—The English Meteorological Office has just published a revised edition of the brochure entitled "Provisional Summary of the Maritime Weather Signals at Present in Use in the Various Countries of the World," which exhibits a remarkable diversity of the signals in question and is a strong argument in favor of the adoption of a uniform code. Hereafter this publication will be revised and issued annually as long as various codes are in use.

**An Aerostatical Weather Station** has been established at Bitterfeld, Germany, by a local firm engaged in the construction of aircraft, and has been placed under the direction of a competent meteorologist, Dr. H. Hultsch. Information for prospective travelers in the air is furnished on the basis of the two-day-old program of the Deutsche Wetteramt, at Hamburg, and who never necessary pilot-balloons are sent up to ascertain the direction and force of the air currents over Bitterfeld.

**A Great Collection of Hebrew Literature.**—The last report of the Librarian of Congress contains an account of a collection of Hebrew literature, which was the national library last year by Mr. Jacob H. Schiff, of New York. This collection was brought into the country during many years by Ephraim Dunbar of Arlington N. J. and included many rare and valuable volumes, some of which were of nearly three and a half millenniums, from the beginning of Hebrew national life to the present day. It is naturally very strong in biblical and rabbinical literature—"It forms," says the report in question, "an admirable beginning of a department of Semitic literature, which the Librarian hopes will develop into one worthy of the national history of a country in which the Semite race is playing so important a role."

**Using the Philippine Scouts to Fight Rinderpest.**—The Veterinary Division of Philippine Bureau of Agriculture is waging an onerous campaign against rinderpest, a disease which in former years destroyed annually upward of half a million cattle and carabao in the Philippines. Through the number has now been reduced to two or three hundred a year. A successful campaign against the disease was made of the Philippine Scouts in warring for a case of the disease and also in patrol duty to prevent the introduction of infected cattle in regions where the disease has been stamped out. Last month the Scouts of the 1st and 2nd regiments, stationed in the southwest as far as south in Pangasinan and northern Marikina leaving the territory behind them free from rinderpest. About 150 of the Philippine Constabulary were utilized in the same undertaking.

**A New Explanation of Global Periods** was presented by Prof. W. J. Humphreys, of the Weather Bureau, at the Cleveland meeting of the Astronomical and Astrophysical Society of America. Several times in recent years it has been observed that great explosive columns of smoke (Krakatoa, Pie, Katmai) were discharged from the upper atmosphere in the southern region, with fine dust, have markedly diminished the amount of solar radiation received at the earth's surface. It seems evident that the effect of this process must be to reduce the intensity of the solar radiation which reaches the earth's surface, a much greater amount of the solar radiation received from without than of the terrestrial radiation received from within, owing to the greater average wavelength of the latter. This period of excessive volcanic activity has been estimated to have produced the climatic conditions of an ice age. The geological record furnishes evidence that such a period actually began shortly before the last ice age and has continued with diminishing intensity to the present time.

**A New Idea in Storm Signals** is now being actively discussed by the meteorological world. Herebefore various forms of flags, cones, drums, lanterns, etc., have been used to warn seamen that a storm is in prospect at the place where the signal is displayed, together with information as to the direction from which the storm is expected to blow in the same locality. These signals are well adapted for use in temperate latitudes, where storms are of great area. In the case of tropical cyclones, however, such as the West India hurricanes and the typhoons of the Far East, they do not give all the information desirable. If a vessel is about to leave port in those regions, the master wishes chiefly to know whether he is likely to encounter a cyclone along his route. A system of signals has been devised by Ben. L. Foss, director of the Zulu Meteorological Observatory near Natal, which may be used experimentally on the China coast, which gives notice of the occurrence of a cyclone anywhere over the adjacent seas, together with its probable course. The International Council of Commerce has suggested the adoption of a uniform code of such "non-local" storm signals for use in all tropical countries.

## Automobile

**International Test for Motor Sleighs.**—The Imperial Automobile Club of Great Britain has organized an international test for motor sleighs to take place in the environs of St. Petersburg on January 19th. The trials will include driving over five sorts of snow-covered roads and three sorts of snow, untrodden snow. The first three of these trials will take place in a special speed trial over both courses.

**Acetylene Tank for Horse Wagons.**—Partly with the idea of making the roads safer for the automobiles and their owners—who, of course, are the last customers of acetylene gas tanks—none of the largest of these companies has long ago introduced a tank for use in horse-drawn wagons. The installation is similar to that on automobiles, the only difference being the size and number of the lamps required. One charging of such a tank will last for fully a month of ordinary daily use.

**Rotary Motor for Automobiles.**—While the rotary gasoline motor has proven a devoted servant in aviation, its use in automobiles has not with very little encouragement so far. Several systems have been given trials, but little has come of the attempts to adapt them for automobile use. The latest of them is the product of two Dutchmen, who have been working hard and endeavoring to enlist the help of some of the large manufacturers. The motor is of the four-cylinder, two-cycle type, and so simple that the complete car, it is claimed, can be built for \$400.

**Carrying Motorcycles on an Automobile.**—The new automobiles ordered by the German government have been fitted with side pockets large enough to accommodate two motorcycles, and have given a good account of themselves in the recent maneuvers. Entrance to the tonneau is effected from the rear and the running boards of the automobile are utilized as storage space. The particular advantage of this arrangement is that, as long as the car is running well, the wheels are out of sight and do not interfere with the free movement of the passenger. Should anything happen to put the car temporarily out of position, the car may be carried in the delivery of messages as the motorcycles would be immediately made ready and mounted by two members of the automobile crew.

**Selling Polish at a Show.**—Some of the exhibitors at the recent London automobile show were ingenious to say the least, and one of them found a novel means to keep his product in the public eye, or rather in memory. At the stand in question metal polish was exhibited and samples were distributed. A man at one end offered small samples, one but he was standing on a metal platform covered with a small tin can of polish. The man stretched forth every hand for the samples received a golden job. Those who were eager enough for a sample and who could overcome their timidity were presented with the tin can, and the man then took the tin can. The theory of the game was that if a people thinking they remember the show and the man's memory brought to mind that particular brand of metal polish. Some time or other the recollection led to a test of the polish. The remainder is obvious.

**\$10,000 Price for New Motor Fuel.**—In order to encourage inventors and chemists the British Society of Motor Manufacturers and Traders has offered a prize of \$10,000 for a volatile fuel suitable for use in internal combustion engines. The only restriction in awarding the prize is that the fuel must be made of such materials or ingredients be obtainable in the United Kingdom in large quantities, so as to make Great Britain independent of other countries in so far as motor fuel is concerned, and that the fuel can be manufactured at a commercial price. The offer is a commendable one, and it is to be hoped that the competition for the prize will lead to the improvement of the carburetor device and the alarming increase in the price of gasoline. The value of the prize itself is, of course, very small when compared with the enormous profits to be derived from a truly satisfactory process of producing the desirable hydrocarbons. It is merely an encouragement in investigation.

**Curbing the Smoke Evil.** With the practical necessity for eliminating the smoke nuisance and the efforts of very nearly every engine manufacturer to get rid of it, that direction, some tests recently conducted by the Royal Experiment Station for Testing Materials at Delft are interesting. A sample of commercial motor lubricating oil was separated into two portions, one portion being treated with an acid which dissolved the heavier constituents without impairing the lubricating value of the oil and the other was tested in its normal condition. The results of the tests demonstrated that the treated oil was as efficient as the normal oil in terms of its lubricating properties, but it was found that the treated oil produced less smoke or irritating fumes. The normal oil, on the other hand, burned emitted considerable volumes of smoke and an odor described as highly irritating to the nose and eyes. The tests suggest that methods in use to reduce the smoke of engines should have directed wrongly and that chemical rather than mechanical means might better be employed.

Finding the protein present in grain by the Kjeldahl method.

## Soil Analysis and Seed Selection

### A New Problem in Agriculture

By L. V. Redman  
Department of Analytical Chemistry of  
the University of Kansas

*The chemist in agriculture is concerned with two main problems. The first deals with the composition of the soil and the availability for plant life of its constituents. The second has to do with the selection of seed according to its chemical composition with the object in view of obtaining, not a greater number of bushels of grain per acre, but a greater yield per acre of one or more chemical constituents contained in the grain. This latter problem, the application of the law of natural selection to the increase in yield of any one chemical compound present in grain, is new and exciting.*—Editor.

An hydraulic hand press of 100,000 pounds for expressing oils, waxes, etc.

NITROGEN, phosphorus, potash and lime are the four "critical" constituents which every soil must contain if it is to be productive and a chemical analysis reveals their presence or absence. A good soil to be termed rich must contain at least 0.4 per cent of soluble nitrogen, 0.25 per cent of phosphoric acid, 1.0 per cent soluble lime and 0.25 per cent of soluble nitrogen compounds. The other chemical elements which make up the bulk of all soils are generally present in large proportions, and considerable variation in the amount of these elements present is not critical. Analysis reveals the constituents of the soil and the amount of each element present, but does not always give in a satisfactory manner the availability for plant food of the four critical elements. The reason for this lies in the fact that it is almost impossible to imitate faithfully the solvent action in the plant cell. No solvent has been discovered which will duplicate the conditions found in the growing cell of a plant. Dilute citric acid is the least single solvent for the purpose, although dilute hydrochloric and nitric acids are largely used by the chemist in this country.

When the chemist has determined the constituents present in any soil he must further determine their availability. The constituent potash will serve to illustrate further the meaning of "availability." If potash is present in the soil as a constituent of the rock fragment it is "locked up" or not available, for the fragment is practically insoluble. However, if the soil be treated with plant food or gypsum, the potash is changed into the sulphate of potash and is readily soluble and available for plant food.

And although a chemical analysis is not as comprehensive as one could wish for yet sufficient valuable practical data can always be obtained by the chemist to pay the cost of the analysis many times over. **Influencing the Composition of Seed by Natural Selection.**

A chemical problem which bids fair to outclass others in importance is the selection for sowing of seed according to its chemical composition. The law of natural selection which is being applied with wonderful success to the improvement of races of domestic and wild, and also to the cross yield per acre in grain production may be applied with equal success to the problem of producing grain which has a more desirable composition chemically than the existing varieties.

To illustrate this point further all grain is composed of three classes of chemical compounds, fats or oils, proteins and carbohydrates (carbohydrates are sugars and starches). The oils, fats, sugars and starches supply heat and muscular energy to the body. The proteins build up the muscles and nervous tissue, and all mental processes are concerned directly with the breaking down of proteins in some form. Proteins are the building materials of muscles and tissues, and the fat of the brain and nerves, just as fats and carbohydrates are the materials for heat supply to the body. Any grain therefore which can be produced which will contain larger percentages of proteins than the existing varieties will serve two purposes. It will have a larger muscle-building value and nerve value, and its heating properties will be reduced. This is of considerable importance when one reflects that most grains such as wheat and oats used in the form of bread or as a regular cereal are at least fifty per cent to two thirds in protein for the best support of the individual. The fat and heat producing factors are consequently fifty per cent too high. In corn alone the protein is

one hundred per cent too low. Consequently, all cereal diets must be supplemented with meats which are very largely protein. If the protein content can be increased one hundred to two hundred per cent in grains, cereals could safely supplant a large part of our meat diets.

With these facts in mind it is evident that any research work which will increase the percentage of protein per bushel of grain will be of great value.

Some pioneer work in this direction has already been done by chemists. For example at the Government Agricultural Experiment Station in the University of Illinois, there has been developed four distinct "strains" of corn, all from the same original seed. The first strain has forty per cent more protein than the original grain. The second strain has twenty five per cent less protein than the original. The third strain contains forty five per cent more oil than the parent corn, and the fourth contains fifty five per cent less oil. These changes have been accomplished by ten years of selection based upon chemical analysis.

What changes may be brought about in ten more years or half a century, of selection is impossible to predict. A much needed improvement in the muscle and nerve value of our ordinary grains may be hoped for, and a corresponding increase in muscle and nerve energy in the life supported on these cereals.

### Atmospheric Ozone Up to Date

ARTIFICIALITY generated ozone has attained a prominent position in technology, and is daily being put to new uses. What of natural ozone that which occurs spontaneously in the atmosphere? Half a century ago this substance was regarded as nature's great scavenger. Then, and for many years thereafter it was a commonplace that an abundance of ozone in the air betokened a healthful climate. "Ozone" was a word to conjure with and figured conspicuously in the advertisements of health resorts. The air of forests, of mountains, of the sea, was supposed to owe its bracing effects to this gas. The degree of sanitation

of the air was tested by the rate of change of some easily oxidized substance, especially the ozone which was devised by Schönbien and variously modified by subsequent authorities.

A deplorable amount of care and labor has been wasted on ozonometric observations according to the traditional methods, which are still kept up by certain meteorologists and hygienists. It has long been known that the so-called ozone reaction indicated by the coloration of wet papers, is due partly and perhaps entirely to other oxidizing agents in the atmosphere, such as the oxides of nitrogen, hydrogen peroxide and chlorine. Moreover an allowance is generally made for the varying strength of the wind (with corresponding variations in the amount of air passing over the wet papers) the hygroscopic action of the papers, and various other sources of error.

Chemists have made quantitative determinations of the ozone present in a given volume of air with remarkably discordant results. In reference hereto it is especially absurd, on the authority of Housman, that country air, a foot above the ground, contains on an average 1,700,000 ozone by volume. This amount would be perceptible to the olfactory, and Housman's estimate supports the popular belief that "ozone-bearing air" can be detected by its smell. On the contrary, Lowry (*Daily Soc. (Chim. de Paris)*, 1908)

was unable to find any certain evidence of the presence of either ozone or hydrogen peroxide in the air but found on the other hand that all the so-called observations of ozone with test paper probably relate to nitrous acid. More recently, Hayhurst and Pring (*Trans. Chem. Soc.*, 1910) made a great number of tests at various altitudes, with the aid of kites and balloons, and found that in every case the amount of ozone was too small to be detected, it is less than 1 part in 4,000,000 parts of air, up to 4,000 feet above the ground while at greater altitudes, up to 10 miles, the amount increased but still remained very small.

Ozone is produced in the lower atmosphere by light ionizing discharges and possibly by other agencies, but probably enters immediately into chemical union with oxidizable substances and therefore has but a momentary existence. The old idea that it is more or less permanently present in regions of the atmosphere inhabited by man, and that its fluctuations are of hygienic importance is hardly tenable at the present day.

Nevertheless ozone exists in the atmosphere and is beginning to be looked upon as a meteorological element of great significance. It is formed from oxygen by electrical discharges and by the action of ultra violet light, and most actively when the gas is dry and cold. It is therefore reasonable to suppose that it occurs most abundantly in the upper atmosphere, miles above the earth, where the amount of ultra violet radiation from the sun is much greater than in the lower air, where there are frequent discharges of electricity in the form of the aurora, moisture is almost all, and the temperature is very low. The solar spectrum always shows strong ozone absorption bands, proving that somewhere in the atmosphere ozone is permanently present. The blue color of the sky may be due partly to ozone. However, probably the most important function of the so-called "ozone blank" of the upper air is its solvent character, in the thermal part of the spectrum, in virtue of which it lets solar radiation in much more readily than it lets terrestrial radiation out. (See SCIENTIFIC AMERICAN, August 28, 1910, p. 107)

Weighting large samples in chemical soil analysis.

# Increasing the Food Supply of a Nation

## How Intensive Farming is Practised in Germany

By Homer C. Price, Dean of the College of Agriculture, Ohio State University

A NATION'S food supply may be increased either by increasing the area cultivated or by increasing the yield per acre. In America we have been using the former method, and in Germany the latter method has been used. Within twenty years the cultivated area of grains in Germany has not increased over 5 per cent, but within this time the total product has increased over 60 per cent, due to the increased yield per acre. This increase has been due to the application of science to the practice of agriculture and has resulted from a better cultivation and handling of the soil from the more abundant and intelligent use of stable manure and commercial fertilizers and from the selection and breeding of more productive varieties of crops.

A comparison of yields between single years is of little value because one year the crop may be abnormal due to an unusual season, but by taking an average for a period of years a representative yield is given that is a safe basis for comparison. In taking the government statistics of Germany and making a comparison between the average yields for the ten years from 1903 to 1912 and for the five years from 1908 to 1910 they show that the following increases in crop yields have been secured by the German farmers within twenty years:

### INCREASE IN YIELD IN CROPS (BOOTS OF GRAIN) MANY IN TWENTY YEARS

Crop	Average Yield Per Acre		Increase in 20 years
	1903-1912	1908-1910	
Wheat	41.2	51.1	24.3%
Rye	10.0	28.1	70.0%
Oats	54.1	87.5	61.9%
Barley	24.0	37.2	55.0%
Potatoes	130.0	210.1	61.6%

Practically the same figures for the United States present a very different picture. Our yields are not only in most cases less than one-half what they are in Germany but the percentage of increase has been very much less as shown by the following table:

### INCREASE IN YIELD IN FARM CROPS OF UNITED STATES IN EIGHTEEN YEARS

Crop	Average Yield Per Acre		Increase in 18 years
	1900-1907	1908-1910	
Wheat	12.7	14.7	15.7%
Rye	12.7	16.4	28.3%
Oats	20.0	20.0	13.9%
Barley	24.8	26.8	8.0%
Potatoes	74.2	80.9	9.0%

While the yield of wheat per acre in Germany has increased 47.8 per cent in twenty years in the United States it has increased only 15.7 per cent, notwithstanding the fact that the yield in Germany is over twice as great as in America. A comparison of the tables will show that what is true of the wheat crop is true of the other crop yields. The German farmer is not only producing much more on the same area, but he is increasing his yield much more rapidly than the American farmer. And yet the German farmer has not reached his limit by any means, and one of the leading German agricultural authorities, Prof. Wobbe, said recently that he was confident the German farmer could increase their present yields 40 per cent within the next twenty years. However this may be, it can at least be pointed out that the German crop yields are constantly increasing from year to year, and as yet there is no tendency to slacken or even stand still.

What has made this rapid increase and why are the yields so much greater than in America? Is the question that naturally arises. Primarily it is due to more intensive systems of farming, and certainly not to land that is naturally more fertile than in America. The German farmer spends much more labor and capital in the growing of his crops than the American farmer.

Harvesting the kind of crops that make Germany independent

A typical German harvesting scene

Courtyard of a German farmhouse

Center of operations on a German farm

His fields are prepared so that they look like a garden and the soil is in the condition before the crop is planted. He is more careful in the selection of his seed and his stand of the crop on the ground is more perfect. He has also learned how to feed his crops with fertilizers. In the first place he scrupulously saves every bit of waste on the farm and returns it to the land. Stable manures are carefully preserved and then judiciously supplemented with commercial fertilizers. The German farmer has learned how to use commercial fertilizers, and he knows they are not to

be used to replace stable manures but only to supplement them. He has also learned the necessity of keeping his land filled with humus to make it crumbly so that it is easy to cultivate and will hold rain water that falls on it. He does this by growing alfalfa and legumes by plowing under green crops and by the use of stalk manures.

But back of all this are two causes that fundamentally affect the ability and effectively work that the German farmer has done to develop agriculture. The European nations shape their policies on a war footing and the standard of efficiency sought is to be able to produce their own food supply in case of war. Indeed long ago stalked his security in his navy and sacrificed his agriculture to manufacturing, and commerce and save up as hoards the products of his own food supply.

Germany, together with the other continental nations has maintained high protective tariffs on agriculture products and accepted it as a fundamental principle of national existence to produce in so far as possible her own food supply.

As a consequence an excellent system of agricultural education has been developed and an extensive system of scientific research in such agricultural experiment stations is maintained. The governments of both individual States and the central government make enormous appropriations for the development of agriculture, all looking toward the increased feeding of the nation. Chambers of agriculture have been established in the separate States and are subsidizing a tremendous influence in the agriculture of the country. They not only take after the ordinary administrative affairs such as the collection of taxes and the like, but they are actively engaged in promoting the business industries of agriculture. They are organizing co-operative societies, distilling, the manufacture of beer, and every means that it wishes to advance the interest of agriculture.

The second fundamental cause of the rapid development of German agriculture has been the efficient business management that the farmers have perfected along co-operative lines. This is particularly true in regard to credit. Intensive farming cannot be developed without an abundant expenditure of money, capital and labor. The American farmer has in general his whole life to do anything, and what the German farmer has done he must have capital that can be secured much more easily and at a much lower rate of interest than is the case in the present time.

German farmers through their land mortgage associations are carrying at the present time over one billion dollars in farm loans and they do not pay over 4 per cent interest for any of it and in many cases not over 3 per cent. They are also over 10,000 rural banks in Germany that are co-operative farmers' organizations, owned and operated by the farmers and having deposits of \$2,500,000,000 through the co-operations in farmers' savings banks for working capital. As a result, farmers are well-served by the industrial class. The banks of the farmer have been made and the terms of repayment are adjusted to meet the requirements of agriculture and in this way the German farmer has a great advantage over the American farmer. He has learned how to use his money and he has learned how to use his land.

The pessimist who predicts the rapidly approaching time when the farmers of the United States will not be able to produce enough for our own needs, let alone the possibility of increasing the production from our present area as Germany has done. It is no reason why America cannot do equally as well if

not better. He also overlooks the possibility of adding to our present area by reclaiming our waste lands. The United States Geological Survey estimates there are 100,000 square miles of swamp land in the United States that can be reclaimed by drainage, and in the reclaiming of the arid lands by irrigation we have much but a starting. The possibilities of the United States may continue to increase for generations at its present rate and American farmers will be able to produce our own food supply if we foster and provide for our agriculture as do the leading European nations.

### The Role of Agricultural Meteorology

HOW much does unfavorable weather cost the farmer? To what extent is the loss from this cause preventable? Is it not true that meteorologists, plant physiologists and practical husbandmen joined their efforts first to find out more about the relations between weather and crops?

We cannot alter the weather; the opinion of Bunday Supplement applies to the contrary notwithstanding. We cannot temper the wind to the shorn lamb, but may not the shearer be circumvented to fit the wind? A thousand acts in our daily life represent so many ways in which we adjust our affairs to the immutable laws of nature. The secret of mitigating the low which weather and climate which is weather in the aggregate, rather than the law in the case of a single day, is in the atmospheric environment. This may be accomplished especially in two ways: first by the selection of varieties best fitted to the climate, and second, by planting, at such a time that the successive species of the climate will be most likely to coincide with suitable conditions of temperature, moisture and the like. It is true that unreasonable weather will sometimes occur and defeat our best laid plans; but in the long run the farmer who times his operations to agree with the nature, and who chooses his seeds in his locality will other things being equal, get the most out of his land. However, before such a plan can be put into effect we must find out a great deal more than is now known about the meteorological requirements of every species and variety of domesticated plant. This is the task of the agricultural meteorologist. Meanwhile his colleagues the physical meteorologist must also the same by carrying out detailed climate surveys of agricultural lands. Intensive climatology is still in its infancy, but the use of climatological statistics are of comparatively little value to the agriculturist because they ignore local features.

There are many indications that agricultural meteorology is at last coming into its own. A notable example on this subject was held at the last meeting of the British Association for the Advancement of Science. An International Commission on Agricultural Meteorology, recently appointed by the International Association of Agricultural Meteorologists, met in Paris last September. Most important of all the International Meteorological Committee itself, which embraces in its membership the directors of the principal national weather services of the world, will hold a conference on agricultural meteorology at its triennial meeting in Rome next April. The International Institute of Agriculture with headquarters in Rome is deeply interested in this subject and has recently published a report showing just what the existing meteorological services of the world are doing for agriculture. With the recent agitation of the subject countries in the world there has spread to our own country and only a few weeks ago the Chief of the United States Weather Bureau assembled a number of his lieutenants at Annapolis to consider what steps should be taken for promoting close relations between that Bureau and the agricultural colleges and experiment stations.

Of all the investigations hitherto undertaken in the scientific horizon between meteorology and agriculture the most gratifying are those being carried out in the Russian government under the direction of Prof. P. I. Broun. About 150 stations, scattered over the empire have been specially equipped for such investigations. Each station comprises small plots of ground on which a series of successive crops are raised year after year and meteorological instruments are installed in immediate proximity thereto, in order that strictly parallel observations may be made upon the crops and the weather. The most important result revealed in these experiments is the existence of certain critical periods in the life-history of each plant when the character of the weather markedly affects the yield. In other words, the total amount of heat, sun and rain and the force received by the plant during the whole period of growth are now being correlated with the occurrence of definite amounts at certain times. In this respect each species and each variety has its special requirements and up to the present only a few attempts have been made to study the problem. Already however Russian farmers have become impressed with the expediency of consulting Prof. Broun and his staff about the choice of crops and the best time to plant.

The farmer lives by the weather, and it behooves him to know as much about it as science can teach him. It is passing strange that there are many agricultural colleges at which no course is offered in meteorology. Strangest of all—while there are many excellent courses in marine meteorology, and in the medical meteorology, and even aeronautical meteorology, an adequate work on agricultural meteorology has yet to be written.

### "Mylrwatt" a New Unit of Power

THERE is no difference in the measure of power whether produced electrically or by steam, by wind or by water power. There is absolutely no reason for holding to the old unit "horse-power," based on the power of an impossibly strong horse, when we have the "watt" based on the rational centimeter-gram-second system, merely because the former is commonly associated with mechanical power and the latter with electrical power. Logically the name of Watt should be more closely associated with steam than with electricity. The term horse-power is falling into disuse among electrical engineers. It is so much easier to rate the power of an engine which drives a generator in terms of kilowatts. In fact, with direct connected engines and generators, it is very difficult to separate the mechanical energy from the electrical energy.

When the electrician can no longer find a unit of the old arbitrary units, there is still to be established a unit that is even more senseless than horse-power for the reason that the name is practically the same, and yet the value is entirely different. Ever since 1875, when the unit was adopted at the international convention, boilers have been rated in boiler horse-power. It is defined as the capacity for evaporating 30 pounds of water from 100 deg. Fahr. temperature of feed water to steam of 70 pounds gauge pressure when the water and the common boiler accessories are both reduced to the common standard of the British thermal unit, we find that the boiler horse-power is thirteen times that of the common horse-power. Clearly then boiler horse-power is a misleading term and has no real reason for existing. In an effort to get rid of "horse-power" entirely a paper was recently presented to the American Institute of Electrical Engineers by H. P. Hott and Haylett O'Neill suggesting that the term "myrlrwatt" be used instead. The term is derived from the Greek "myrion," meaning ten thousand, and the term "watt." One boiler horse-power very nearly equals ten kilowatts or ten thousand watts. Hence "myrlrwatt" in terms of British thermal units, one kilowatt is equal to 3,415 units per hour and one boiler horse-power to 38,475 units per hour. The "watt" would then be 3,150 British thermal units per hour or only two per cent more than the boiler horse-power. It is the common practice to rate water tube boilers at one boiler horse-power per ten square feet of heating surface. As this is an arbitrary measure, no harm can be done by increasing the unit two per cent, and boilers might hereafter be rated at one "myrlrwatt" per ten square feet of heating surface. At a joint meeting of the Standard Committee of the American Institute of Electrical Engineers, and a special committee appointed by the American Society of Mechanical Engineers, the new term was recommended and Mr. C. O. Mallows was appointed to present this unit to the International Electro-Technical Commission at Zurich. It seems quite probable that the term will be adopted abroad, where "boiler horse-power" is never used, and no suitable substitute exists.

The new term permits the use of a simple system of determining the over all efficiency of a plant. For it is only necessary to divide the kilowatt output by the myrlrwatt and multiply by ten to obtain the per cent of efficiency. The input of a plant and its output need no longer be reduced to different and unrelated units of power. All power can be measured in terms of a single unit. Blessed is the man who makes one word grow where two words grew before.

### Télesme de Bort (1858-1913)

AMERICAN meteorologists thought of the late Léon Télesme de Bort as "the French Metc," and of the late A. Lawrence Roth as "the American Télesme de Bort." Both men enjoyed ample private fortunes and were generous patrons of meteorology; each of them built and directed a private meteorological observatory, and each was the great pioneer aerologist of his country. This parallel has unhappily been completed by the death of both in middle life, and with a few exceptions of each other.

Télesme de Bort was born in Paris, November 26th, 1858. From 1878 to 1892 he held an active position, and from the latter year onward an honorary position, on the staff of the Central Meteorological Bureau of France. In 1898 he founded his observatory of dynamical meteorology at Trappes, just a few miles from Paris, and here he began about 1899 the series of sounding-balloon ascensions which led to the astounding discovery of the isothermal layer of the atmosphere—first formally

announced to the French Academy of Sciences in 1903. Twentieth century meteorology may be held to date from this achievement, as nineteenth century meteorology did from the discovery of the law of Fourier.

Bort had not only discovered the isothermal layer, which he subsequently renamed the "stratosphere"—Télesme de Bort would rank with the greatest meteorologists. His idea of "centers of action" in the atmosphere is pregnant of practical and theoretical results not yet fully realized. He was one of the foremost advocates of the world wide outlook in meteorology and the founder of the plan of collecting daily meteorological reports by telegraph from stations all over the globe now being elaborated by an international commission, which he had presided over. His charts of high level isobars, and his discovery of the relations between anomalies of temperature and pressure, marked definite advances in our knowledge of the atmosphere. He was one of the creators of the International classification of clouds. He joined with Roth in fitting out the expedition, known as the yacht "Oreia," which established the existence of the antitropical winds above the north-east trade.

In company with H. H. Hildebrandt he began some years ago the publication of a general work on dynamical meteorology, unhappily not yet completed. In 1906 he received the Hymons gold medal of the Royal Meteorological Society, which is awarded every two years "for distinguished work in connection with meteorological sciences." He was recently elected a member of the Academy of Sciences.

### The Growth of Stumps

IT occasionally happens, particularly with trees growing in wet or very moist soils, that stumps of the Cuban pine (*Pinus itzabopalis*) and long leaf pine (*Pinus palustris*) continue to grow by laying on very narrow annual rings of woody tissue for a number of years after the trees have been felled. The stumps of Douglas fir (*Pseudotsuga latifolia*) and redwood (*Sequoia gigantea*) likewise continue to grow in diameter for a longer or shorter period of time. It was observed some time ago in Florida that a good many stumps of Cuban and long leaf pines felled more than ten years previous had continued to form annual new layers of growth. These annual rings are very narrow, often only from three to six cells wide, and are indistinctly visible even under the high power of the microscope.

What appears to be the cause of this phenomenon is how the roots retain their vitality for such a long time and supply the cambium of the stump and larger roots with a sufficient amount of manufactured food to deposit layers of wood. Before the food material can be utilized and the tree is not cut, the cambium in the leaves. A chestnut tree, for instance, produces new shoots from the root collar as soon as it is felled and the leaves on these young shoots supply the root system with elaborated food. The stump thus can flourish to live, but the pine to which the chestnut stump shoots and can not manufacture food material for themselves. It would seem reasonable to conclude, therefore, that the roots of these pines are parasitic and are granted on those of the neighboring trees, which supply the pine stumps with the required amount of prepared food. The roots of closely allied species of trees often unite, especially in shallow wet soil, where the roots of both young and old trees are near the surface and necessarily come in close contact with one another.

The irregularity with which the wood is often deposited clearly indicates that the roots of only one side of the stump have joined those of the living tree. Sometimes the wood deposits on one side is more than double that on the opposite side. This new wood produced is often scarcely distinguishable from that formed naturally. The fibers or tracheids are usually interlaced and in an isolated state are curved and have blunt ends. The markings on the cell walls are similar to those of normally formed tissue. The compound microscope reveals the fact that the cell walls are slightly thinner and that there is little or no distinction between the early and late wood in these narrow zones.

### Rolland Gas Exposition

THE gas exposition of Amsterdam, which closed October 15th, 1913, numbered among its exhibitors 300 firms of different countries, only one of which was from the United States. It contained some interesting exhibits, such as the model of a Detroit factory for making gas from petroleum residue by means of a high pressure distillation. This invention is considered of special importance to the United States on account of our large production of petroleum. Other exhibits included a safety gas meter having automatic device for preventing gas from petroleum residue by means of a small lighter having a lighting switch against the wall, and a burner and mantle which can be used with either gas or kerosene.

## Effect of Reservoirs on Freshets

To the Editor of the SCIENTIFIC AMERICAN

Mr. H. R. Plint's article on the control of the Mississippi, in your January 11th number, contains an important fallacy which should not be passed unchallenged. Mr. Plint provides that the existence of reservoirs, even those of "many square miles in extent," does not regulate or equalize the flow, for the reason that "the extra water that causes the flood comes on top of reservoirs already filled" by previous rains. This is a misconception, however, he is quite mistaken, even if it were not true that the level of reservoirs in all modern constructions can be and is regulated according to requirements. The rate of flow over the spillway of a dam varies with the amount of the head or level of water in the reservoir above the given edge of the spillway, and this head will of course, for a given quantity of water flowing into the reservoir, vary inversely as the reservoir's area. This is a fact of such common observation, even aside from any mathematical consideration, that no demonstration is required. Water powers on streams are rendered useless in proportion to the storage capacity of the reservoirs back of them. The immense value of Niagara's power consists largely, if not mostly, in the greatest power reservoir in the world which lies just back of it.

Of course, the existence of a reservoir may "lower the ultimate high-water mark attained by the stream" by just the amount of water added to the reservoir, and inversely as the time it takes to run out.

There is not in any sense any "back up" to the influence of a forced watershed on stream flow, as Mr. Plint assumes, because when the ground is saturated, the "reservoir" is filled to capacity and no longer stores any water. MILWAUKEE, WIS. GEORGE W. COLLIER

## The Alaska Reindeer Industry

To the Editor of the SCIENTIFIC AMERICAN

I have just noticed in the issue of January 4th the letter of Mr. A. W. Williams, of Chicago, Alaska, regarding the Alaskan reindeer herds, which, in the wide circulation of the SCIENTIFIC AMERICAN, I consider worthy of notice.

Mr. Williams implies that the Bureau of Education's reindeer enterprise in Alaska is unsuccessful in that it does not provide a draft animal for each settler, producer, throughout all of the vast and varied regions of Alaska.

Mr. Williams has entirely misconceived the object of the Bureau of Education in this undertaking. It is neither the duty nor the endeavor of the Bureau of Education to furnish Alaska with reindeer, but to train and a most producer. Its Alaska reindeer industry is confined solely to the native population of Alaska, its object is to provide assured means of support for the native of the vast untimbered grazing lands of northern and western Alaska, which are adapted for reindeer raising in this it has been eminently successful.

Instead of being "confined entirely to narrow strips of land bordering the oceans," the reindeer industry affects a region approximating in length the distance from Maine to South Carolina. In this region reindeer herds are found in the valleys of the Nomsak, Kobuk, Selawik, Yukon, Kuskokwim, and other rivers, at many points hundreds of miles from the coast. The northernmost herd is near Point Barrow, on the shore of the Arctic Ocean, in latitude 71 degrees 57 minutes, longitude 156 degrees 20 minutes; the southernmost herd is at Ugnak, in southwestern Alaska, forty miles from the North Pacific Ocean, in latitude 57 degrees 50 minutes, longitude 154 degrees 50 minutes. A straight line from Point Barrow to Ugnak is 3,100 miles, and the average length of a line connecting each of the fifty-three herds would be more than 5,000 miles in length.

The official reports for the fiscal year ended June 30th, 1915, show a total of 36,507 reindeer in Alaska, of which 324 native ones 24,000 or 25 per cent, produced at an average value of \$25 a couple of \$500.075. The total income of the natives from the reindeer industry during the fiscal year, exclusive of value of meat and hides used by the natives themselves, was \$44,885.04.

Mr. Williams's statement that my "figures are based upon the number of reindeer referred to above" shows several errors in order to enable the reader to reach their food," and that the Government had required "the continual services of between thirty and forty men to shoot more of the moose" or to get the reindeer in without destruction. No men were employed to shoot moose and, as far as I know, none was shot. On the trip to Ugnak he has referred, I used reindeer as draft animals all winter, serving a million countrymen on Ugnak in the Chukchi Bay, 600 miles from Ugnak and Thapsig, involving a distance of more than 2,500 miles, and to complete the journey with that of the best team in Alaska, when post, weather, and condi-

tions of trails are taken into consideration. I neither broke trails on snow shoes, nor pushed behind hand bars—I rode. W. T. LORR, Chief of Alaska Division

## What is Mentality?

To the Editor of the SCIENTIFIC AMERICAN

In recent years I have had more or less to do with feeble-minded people, and have come to a new realization of how much mentality depends on physical organization. This exposure has materially modified theories previously held as to the possible of the individual mind.

My present theory is this: Mentality, thought, consciousness, whatever you will, is the expression of the reactions that occur between nervous (electro-chemical) energy and energy generated in the organs of the mind. The brain alone is usually spoken of as the organ of mind, but the brain in itself is as powerless to produce mental action as a dynamo to produce electricity without conjunction with some external force. This external force is the mass of the brain in the energy produced by the blood, and brain action ceases at once if the blood supply is shut off, and the individual drops into the blank of extinction.

A long array of facts, inseparable by the brain theory, are reasonably explained on this hypothesis of mind and blood interaction. The normal mind arises from normal blood and brain. When either of these is abnormal, or both abnormal, the resulting reaction is abnormal and we have the abnormal mind.

The animal body is a wonderful chemical laboratory, and the blood in manufacture is composed of mind, chemical elements contributed by the numerous glands and other tissues. Now if any of these glands and tissues are defective or absent, so that the elements they furnish are defective or missing, the blood is thereby made defective and ineffective mentality results. If a person has a diseased thyroid gland, or if it is missing, we have the cretin, a feeble-minded person. If this gland has such decided influence on the quality of mind may it not fairly be assumed that other glands have a similar influence? Indeed, we know they have. The gland has neither the robust mentality nor the robust physical constitution of the entire animal.

In all the past and up to the present, mankind has been unable to discover the real nature of insanity, epilepsy, feeble-mindedness, because they have looked for the cause in the brain alone or in the nervous system, or in the secretions alone—the secret lies probably in the reactions indicated and these have been and are still beyond detection.

Recognizing that comes into existence does so through some process. In a universe where everything is inseparable in its ultimate to the human understanding is this hypothesis as to the genesis of the individual mind unreasonable? Heretofore we say: "From this ocean of life in which we are immersed, we are incessantly drawing something and we feel that our being, or at least the intellect that guides it, has been formed therein by a kind of local concentration." Supposing that there is an ocean of life or an ocean of mind with there must be an individual process to generate the individual life or mind, there must be this "local concentration" as Bergson terms it, and why should not the interaction of blood and brain energy be the process, seeing that both are necessary to life and mind?

Of course individual, conscious immortality is destroyed by this hypothesis, for when the complex of forces is dissolved out of which the individual arises, body and mind, the personality is forever dissolved.

Perhaps this theory is not new, but so far as I am concerned it is. It is similar to the theory of the "perfect spring wheel." It is the truth, so far as we are able to comprehend the truth, that we want.

Fairbairn, Minn. EDGAR OGDEN

## The Fallacy of the Spring Wheel

To the Editor of the SCIENTIFIC AMERICAN

For purposes of comparison, assume that a vehicle is equipped with full elliptical springs between the body and the wheels and that the wheels are "perfect" spring wheels. When a load is imposed upon the vehicle, the elliptical spring and the bottom and top spring of the wheel will be depressed. This depression we may call the normal depression. If the wheel is to have the same shock-absorbing efficiency as the elliptical spring, then the normal depression of both must be approximately equal. In the case of the wheel springs, however, it is clear that the springs above the hub of the wheel and the springs below the hub are fixed in opposite directions, so that in one revolution of the wheel the spring in it must undergo a course of double the normal depression. Therefore, if the vehicle was driven over a perfectly level road, the elliptical spring would simply remain in the position of normal depression while the springs in the wheel would undergo a double depression. If the road is of the normal depression at every revolution. The spring of a 40-lb wheel would therefore maintain approximately 80 double normal flexures in every mile in addition to

the flexures caused by the absorption of irregularities of the road.

The working of the springs due to the irregularities of the road will be the same in either case. Now, if we represent the amount of this working per mile by  $X$ , the normal depression by  $Y$ , and the miles by  $M$ , we can represent the comparative working of the two springs as follows:

Work in elliptical spring,  $MY$

Work in spring wheel,  $MX + 1,050 Y$

The springs in the wheel must therefore undergo 1,050 complete normal flexures in each mile more than the elliptical spring. This would develop an amount of heat and a rate of depreciation in the spring wheel which, in the opinion of the writer, makes it practically certain that no spring wheel, however ingenious and perfect in action, will ever become a practical success.

This same reason is recognized, even by the layman, as the cause for the rapid depreciation in automobile tires, but, so far as the writer is aware, has never been recognized in connection with the spring wheel.

Plainfield, N. J.

## Panama Canal and Free Tolls to Domestic American Shipping

To the Editor of the SCIENTIFIC AMERICAN

The note of Karl Gray to the Government of the United States in protest of the free tolls to American domestic shipping using the canal in trade between United States ports, makes it practically certain that no spring wheel, however ingenious and perfect in action, will ever become a practical success.

That would hardly seem to enter into the race, at least not for many years, as Prof. Ernest Johnson pointed out in his report to the United States Government that the United States would have to make up the deficiency in the canal revenue for years to come, even though American ships paid tolls.

So far as foreign tonnage is concerned, the United States allows foreign tonnage to use the canal at less than cost.

Free tolls for American domestic shipping is untenable from every and any standpoint. It is in effect a subsidy to great a monopoly as exists on the sea—American coastwise tonnage.

American coastwise tonnage is shielded from the competition of any foreign steamers. None but American-built craft can now engage in trade between the United States Atlantic-Pacific ports.

To give this tonnage free tolls is the same as handing it money from the United States treasury, and no thought whatever is given to the interests of shippers. No thought is given as to the possible combination that may be effected by the owners of American coastwise tonnage that will engage in the trade.

And from the present reports of the activity in shipyards the world over, including the United States, it would not be surprising to find a demand for the construction of a year or two, it would be a difficult matter to place an order for tonnage and secure anything like prompt delivery, freight meanwhile being at the mercy of tonnage owners that have no more hesitation in clearing all the traffic will bear than have railroads.

And besides this, there is a phase of the matter that so far has apparently not been touched. American steamers engaged in trade to foreign ports and using the Panama canal will have to pay tolls. While American steamers engaged in coastwise trade using the canal will go through free.

On what grounds can Congress make such a distinction? It is clear legislation pure and simple, discrimination of the worst sort, taxing American steamers engaged in foreign trade more than those that do not use the canal.

No one has ever claimed that we would have to extend aid to tonnage to uphold our coastwise trade. The efforts that have been made in Congress in the last decade have been in behalf of American tonnage that was to uphold our deep-sea foreign trade. American tonnage on the deep sea "could not stand the competition of foreign steamers." "It cost more to operate the American, cost more to build and compete. It was necessary that Congress extend aid in the shape of bounty or subsidy to our coastwise tonnage. It is the course of the American merchant marine that did make a somewhat plausible showing, that needed aid, and that gave a measure of subsidy—for that is what free tolls is in effect—to that part of the American merchant marine that not alone needs no subsidy of any kind but which is and has been favored as has the shipping of no other nation.

In the interest of American far play the free toll measure should be rejected, that would be one equitable act. And not only that, the principle of justice should be put on the ground of discrimination there is nothing in the Constitution or in law that permits Congress to levy tolls on American shipping using the canal and devolved for ports and tonnage engaged in foreign trade, but to exempt American ships destined to ports of the United States.

Hauling twenty-two and one half yards of crushed rock in five dump wagons.

## Economics of the Farm Tractor

The New Way of Tilling the Soil and What it Means

By Philip S. Rose

SINCE the very dawn of time agriculture has depended upon the muscular power of man and animals to perform all of its heavy work. Even after all of the other great industries had adopted steam or gas or electricity, agriculture continued to plod along in the time honored custom, because forsooth nothing else was available. This condition continued until very recent times. About a dozen years ago the steam tractor was developed sufficiently to attract the attention of many of the large western grain farmers and then, less than ten years ago the gas tractor using gasoline or low grade kerosene for fuel, made its first appearance. From that time forward the pace has been rapid.

Farmers everywhere are now talking about power farming and thousands have become converts to the new idea. Six years ago there were not to exceed five hundred gas tractors in the United States. Last year more than thirteen thousand were sold, and this year the factories of the United States will turn out no fewer than twenty thousand. Five thousand of these will be sold in western Canada. Of the remaining fifteen thousand some will go to South America, some to Russia and some to the various countries of Europe, but the greater number will be sold to the farmers of the United States.

Next year more than twenty thousand will be made and sold. The demand is greater than the supply and continues to increase from year to year. There are now more than thirty companies engaged in their manufacture, and new ones are being formed almost weekly.

Such is the condition of the business, and its prospects for the future seem very bright indeed. It looks as though the commercial success of the automobile were to be repeated in the farm power field.

All this activity is easy to understand when one comes to consider the immense expenditure for power necessary to conduct the agricultural operations of the

country. The total cultivated area of the United States is 477,488,000 acres, of which a little more than 43,000,000 is annually devoted to the hay crop, thus leaving about 435,000,000 acres that must be plowed and made ready for the crop each year. It is estimated that the average work necessary to plow an acre is about ten horse-power hours. At the Winnipeg Motor Contest last year the average of all trials showed that it required 15.41 horse-power hours to plow an acre, so the figure selected appears to be on the safe side. Using this as our power factor, we find that the total expenditure of power for plowing the ground once each year is 4,350,000,000 horse-power hours. In order to accomplish this task and do the other necessary work, which amounts to more than twice as much additional, there were on January 1st of the past year, according to the report of the Secretary of Agriculture, 24,002,882 horses and mules on the farms of the United States. Their total value, as given by the same source, was estimated at \$2,088,351,000. The average value per head is thus \$112.03, which is certainly low enough. These animals are maintained almost exclusively for farm power use, and do not include those used in cities and villages. If we take into account the harnesses and other gear required before this power is available, estimated at fifteen dollars per animal, it is evident that the farmers have the prodigious sum of three billion dollars invested in power equipment.

If we assume in round numbers 400,000,000 acres as the total cultivated area, and three billion dollars as the investment, a

Billows of earth left in the wake of a tractor plow.

Majestically a huge tractor moves through acre after acre, drawing in its train a dozen agricultural implements.

Little calculation will show that the farmers of this country have an average of \$625 an acre invested in animal power. This sum seems excessive, but as a matter of fact it is greatly exceeded by many farmers. The truth of the figure becomes apparent when one considers that they provide only two work animals to each forty acres of cultivated land. Needless, the estimated value per animal is very low. There are hundreds of farms where the cost per acre is greatly in excess of the figure given.

Authorities differ as to the annual cost of keeping a horse. Grisdale, of the Ottawa Experimental Farms, reports an annual cost of \$69.80 for each of the nineteen horses at the station farm. Burckett, of the New Hampshire Station, reports the average cost of keeping five horses at \$74.88 each, while Cooper in Minnesota found the farm cost of keeping horses to vary from a minimum of \$65.23 to \$90.40. If we assume an average cost for the entire country of \$75 per head, which seems reasonable in view of the above figures, we find the total cost of maintenance of this important industry reaches the enormous sum of \$1,800,400,150 or \$1.76 per acre.

The total value of all agricultural products for the year 1911, as estimated by the census is \$4,417,000,000, which amounts to \$17.53 per acre for the entire United States. From this it will be seen that it requires 24 per cent of the products of the farms to maintain their work animals. In this discussion, of course, more than one hundred million acres are required to raise food and pay for the maintenance of the horses and mules of the United States. Truly this is an enormous tax upon our national resources and at a time, too, when the production of human food is not keeping pace with our increasing population. Is it any wonder that farmers are looking toward mechanical power with eager hopefulness? These animals do not furnish food or clothing directly and hence their total cost must be chargeable to the annual national farm power bill. In this discussion, it should be especially noted that we have omitted all interest and depreciation charges. If these were taken into account, we should have to add about sixty-two cents more to the maintenance charge per acre which would bring the total up to \$4.86, or almost exactly twenty-five per cent of the country's agricultural production annually.

While perhaps few farmers have ever kept an accurate account of the cost of keeping their work animals, they are nevertheless aware that they are paying an enormous price for the power needed to do their work. Not only are they paying a heavy price for the power itself but the fact that it is divided up into such small units makes it necessary to employ many extra laborers during the busy season. The change to mechanical power operates in agriculture just as the adoption of improved machinery in manufacturing. It reduces the number of men required to perform a certain piece of work, and thus reduces the cost.

Owing to the nature of farm work and the fact that there is a long idle period during the year, it is difficult to maintain enough laborers in the country to do the work during the busy season. This fact, coupled with the high maintenance cost of work animals, has turned the minds of farmers toward mechanical power. They desire a power which will be a tractor instead of keeping a dozen or more horses. The tractor does not require special attention during the time it is idle. It does not cost anything for the while idle. It does not require as many operators as the horses it replaces, and it is able to turn out more work in a day. Moreover, it is able to work longer hours and during the hottest weather. The speed with which it can prepare a field for a crop or the ground after it is prepared is an important item, for it is well known that the soil is often in the best condition when the ground was plowed or the moisture content of the soil when the seed was planted. A rapid machine like a tractor enables the farmer to take advantage of soil and climatic conditions more successfully than when he depends upon horses.

It is true that the tractor is not adapted to the small farmer. It costs too much. Prices now range from \$1,500 to \$5,000. The highest price is for the larger machines which will develop anywhere from fifty to eighty horse-power.

These machines can easily do as much as twenty-five or thirty horses, while the smaller machines, which will develop from fifteen to fifty horse-power, are

fully equal to ten or a dozen horses. The first cost of the larger machines is not much if any greater than that of the horses which they replace while the cost of the smaller machines is not greatly in excess.

It is the general opinion of well informed tractor men that it will pay any farmer who has ten hundred or more acres under cultivation if his land lies right, to purchase a gas tractor. For a farm of that size he will need one of the smaller machines. This power bill for the year should then figure about as follows:

Interest at 4 per cent	\$72
Depreciation	230
Fuel, oil and labor	100
Total	\$402

At the average of \$4.38 for all horse labor the total would have amounted to \$670. These figures show a gain of \$444 for the tractor.

Any set of estimates are liable to be misleading. Much depends upon the character of the farm where mechanical power is contemplated as to whether it will pay to make the change or not. The kind of farming and the mechanical ability of the farm owner or man are the items that must come in for careful consideration. Perhaps the best way to approach the subject, and thus arrive at the fact is to consider the experiences of those who have used gas tractors.

Pulling blades by engine power

A horseless tractor that does the work of many teams.

Hauling logs in Tennessee over roads that are roads only in name

There is no place in this country where power farm has been carried on more extensively than around Bozeman, N. D., and Williston, Montana. The farms are large and horses are used merely for driving purposes and to haul light loads from town if the farmer does not possess an automobile. All the heavy work such as plowing, disk, seeding, threshing and hauling the crop to market is done with tractors. Many steam tractors are used, but gas tractors are the favorite.

As an example of the amount of work a tractor can do in a season, take the record of E. G. Paul on one of the Bozeman tractor farmers. Last year he plowed 810 acres of sod, disked 900 acres, seeded 1,000 acres, harrowed 1,440 acres and threshed and then hauled his grain to market besides doing a considerable amount of road grading. E. A. Bessley, a prominent farmer near Lake City, Iowa, says he finds his tractor more economical and satisfactory than horses. Joe McIntosh, another Iowa farmer, reports that it cost him less than eighteen cents an acre to do his plowing last fall with an engine burning distillate. He used two and three quarter gallons an acre, which cost him six cents a gallon.

The most of Montana has been developed with mechanical power, and the three western provinces of Canada depend upon it. It would seem if these Canadian farmers can make power farming pay that the

farmers of the United States would certainly find it profitable. In order to obtain some idea of the costs of operation and to obtain an expression of opinion regarding the efficiency of the tractor I sent out a list of questions to forty farmers in Montana, asking the cost of fuel, cost of outfit, other charges, repairs, etc. and finally asking for an expression of opinion in regard to the future of the gas tractor. Eleven replies were received and every one expressed the opinion that the gas tractor would be the future of the kind of power in Canada. This too in face of the fact that tractors cost twenty-five per cent more than in the United States, and fuel fifty twice as much. Several reported using gasoline that cost twenty-seven cents per gallon and yet they were enthusiastic for the gas tractor.

The work reported as being done by tractors covers a wide range and includes all field operations, such as plowing, seeding, harvesting, hauling to market, threshing, corn shelling, grading, hilling, haying, filling ditches, and road grading.

There is no question but we have entered upon a new era in agriculture. The farmer desires the comforts and advantages of the city dweller and thus he has moved easily and cheaply with the small gasoline engine. He sees that the gas tractor is suitable for the heavier field operations and is generally more economical than horses, and he is not slow to make the change. It is worth noting that the only drawback to the gas tractor is its cost. It multiplies his capacity and gives him other leisure or enables him to farm a larger area and increase his income.

Power farming has just begun, and the start is encouraging. Whether it will accomplish the revolution in agriculture that it has in manufacturing and transportation, can only be seen, but it seems safe to predict that it will bring about many interesting social and economic changes.

## X-ray Pictures of Micro-organisms

By Dr. Alfred Grassl

THE latest advances in the field of radiology is the use of X-rays for examining microscopic preparations. If in spite of the many added applications of X-rays, no attempt had so far been made to use them for microscopic study, this was doubtless due to the first one experimental difficulties that have come.

A French scientist M. Bertoin, who at first has however by means of a special apparatus (particulars of which will only be made known in a short time) succeeded in removing these difficulties and investigating opaque microscopic preparations by radiology in all their most hidden details.

As pointed out by a memoir recently submitted to the French Association for the Advancement of Science, study at first placed his micro-radiographic work in the service of paleontology and embryology. The most primitive organisms (protists) all kinds of foraminifera and similar microscopic beings can thus be investigated in their innermost structures. (Note: has even succeeded in ascertaining the existence of the nucleus in species which ordinary methods of investigation only showed the existence of a single species.)

It is known that sea and contain fossil remains of all sorts of microscopic organisms. When examining a sample of such sand under the microscope X-ray apparatus, a surprising abundance and variety of forms is revealed each individual being analyzed far more safely than under the microscope. In addition to these applications, micro-radiography also lends itself for investigating the formation of the bones of small vertebrates from their birth to the adult stage. Apart from the structure of bones, peculiarities of the skin and any anomalies of small though not microscopically small animals can be studied. The method would seem to give an adequate idea of the possibilities of this new science the further development of which will be left to the experimenters themselves.

The Library of the Late Prof. Skene has been presented to King's College, London, where, with the library of the late Prof. Furnival, presented to the same college, it is to form a department of the School of English Language and Literature.

# The Heavens in February

How Astronomical Predictions Have Been Verified in the Laboratory

By Henry Norris Russell, Ph D.

**P**ROBABLY the most remarkable feat of astronomical spectroscopy has been the detection of spectral lines in the light of the solar atmosphere of the rays coming from long before this element had been run to earth in our laboratories. A similar story lately has remarkable lines just come to its final chapter in the prediction of the laboratory of a set of lines in the hydrogen spectrum, long ago known to exist in the stars.

In some ways this task is even more remarkable than that of helium. It is not enough to understand that when astronomers find in the spectrum of the Sun's chromosphere a number of lines that cannot be reproduced from any known substance, under any known method of treatment they may legitimately assume the lines to be due to some unknown gas, and call it helium from the place of its presumed occurrence.

But in the case now under discussion a number of spectral lines have been observed (111 many years later) in the laboratory, have been confidently assigned to hydrogen, one of the most familiar of substances, and, what is more, the positions of other lines of hydrogen have been observed in the stars, and have been predicted, and after fifteen years these assumptions and predictions have been triumphantly verified by experiment.

To understand how these truly extraordinary things have been done, we must consider for a little the fascinating subject of series of lines in spectra.

In the spectra of many elements, there exist sets of lines, sometimes single, often double or triple which show a regular spacing, the successive pairs lying nearer to one another and becoming fainter toward the violet end of the spectrum. When the number of lines in the spectrum is great it is often difficult to pick out such series; if this is done, but in spectra showing no fainter lines, the series are often the most conspicuous features.

Perhaps the finest of all examples of such a series is the great system of hydrogen lines which are so conspicuous in the spectra of the white stars (like Sirius) and appear also with less intensity in the solar spectrum. The same lines may be produced without difficulty, by passing an electric discharge through hydrogen contained at low pressure in a vacuum tube. As long ago as 1865 Balmer showed that the wave-lengths of these lines (which define their position in the spectrum) could be calculated with great accuracy by the formula

$$\lambda = 164.17 \frac{m^2}{n^2 - 4}$$

in which  $m = 1$  gives the wave-length of the red line (called  $H$ ) in the solar spectrum;  $m = 2$ , that of the blue  $F$  line, etc. The remaining lines lie in the violet and ultra-violet parts of the spectrum, and lie closer and closer together crowding toward a definite limit, only about a light of them can be photographed in the spectrum of the vacuum tube. In the stars and the solar chromosphere, where conditions seem to be in some way more favorable many more can be seen. In fact, all the lines of the series as far as  $m = 31$  have been measured on Eddington's eclipse photographs, and the agreement of the observed and calculated wave-lengths is practically perfect.

Study of other elements showed the existence of similar but somewhat more complicated series. The sharp, metallic-sodium, potassium, etc.—show in their spectra three series of pairs of lines, which may be treated for calculating their positions become simpler if we take, not the lengths of the light waves, but the number of waves in a given distance as a criterion. When this is done it is found that the interval between the lines of a pair measured in this way is exactly the same for all the pairs belonging to two of the three series while the third series is composed of pairs which grow rapidly closer as the lines lie farther to the violet.

The first two series of lines have the same limit, toward which the successive pairs converge, while the limit of the third series is usually far in the ultra-violet. This last series contains the strongest lines in the whole spectrum and is consequently called the "principal series." The other two "subordinate series"

of fainter lines may be distinguished from one another on the fact that the lines of one series are usually sharp, and those of the other usually diffuse when examined under high dispersion. These sharp and diffuse series are so arranged that the pairs of one sort and the other alternate in the spectrum, presenting a very beautiful picture, which can be seen by any one who can look with a spectroscope of very moderate power at an electric arc whose carbons are plentifully treated with some salt of sodium.

It will not do, however, to use a Penman burner, for, at the relatively low temperature of its flame, only the lines of the principal series of sodium are visible, and but one pair of these—the familiar lines in the yellow—lie within the visible spectrum. It is not until the atoms of the metallic vapor are exposed to the more violent disturbances, thermal and electrical, which befall them in the electric arc that they begin to vibrate in the waves, and at the rates, which give rise to the lines of the subordinate series.

A very interesting numerical expression for the wave-

lengths of the series of lines is a more complicated algebraic expression.

The bearing of all this on hydrogen and astronomy is as follows. In 1869 Pickering discovered, on photographs of the spectrum of Zeta Puppi (now visible low in the southern sky) a series of lines in the middle of the intervals between the familiar hydrogen lines, and very like them. On measuring their wave-lengths, he found that they could be very closely represented if, in the well-known formula of Balmer, the values  $m = 316, 416, 516$ , etc., were inserted instead of 3, 4, 5, etc. This was evidence enough to make it very probable that the new lines were really due to hydrogen, whose atoms were stirred up to vibrate (perhaps by very high temperature) in additional ways, besides those already familiar, just as happens to the sodium atoms in passing from the flame to the arc.

Rydberg, after Pickering's measures were published, promptly showed that the positions of the lines could be very accurately represented by a formula of his type. The two series of hydrogen lines appeared to be related just like the two "subordinate series" in the spectrum of sodium, etc., the familiar lines corresponding to the "diffuse" and the new to the "sharp" series. It was now possible, using the last formula which is written down above, to predict where the lines of the principal series of hydrogen ought to be, if the previous hypotheses were true.

One of these predicted lines of wave-length 4,088 on the usual scale, in the blue, agreed with the uncertainty of the measurement with a bright line observed in the spectrum of Zeta Puppi and some other stars, and also in the spectra of some nebulae, and (as was later shown) faintly in the Sun's chromosphere. The other predicted lines lay in the extreme ultra-violet, with wave-lengths less than half that of the  $D$  lines. For light of such short wave-lengths, our atmosphere is very largely transparent. The closeness of a few feet, such as come into question in laboratory measurements, exert a moderate absorption, but the miles of air through which the light of the Sun and stars must come, for these rays, entirely opaque.

There was hence no further possibility of testing Rydberg's brilliant hypotheses by astronomical means.

So the matter stood for fifteen years, until Prof Fowler of North Kensington, and a very distinguished spectroscopist as a thority, discovered, only a few months ago, a very powerful electric discharge is passed through a mixture of hydrogen and helium, in a vacuum tube, the lines under discussion can be observed. Hydrogen alone has not yet been made to give the new spectra, but from the reasons already given there is no doubt at all that it, and not the associated helium, is responsible for them.

The measured positions of the lines of longer wave-length agree perfectly with those observed in the stars, and the lines of the principal series are there, in just the calculated positions. An additional set of lines, intermediate between those of the principal series, and forming a fourth series, related to it very much as the other two series are related, have also been shown in the ultra-violet that they are of no astronomical importance.

It would hardly be possible to find a more beautiful instance of the confirmation of scientific predictions; and all concerned in the discovery, Prof. Rydberg, and Prof. Fowler—may well receive the heartiest congratulations upon the completion of this almost romantic chapter of spectroscopic history.

## The Heavens.

The winter constellation map is so familiar that we need not linger long over our map. We need only find Orion in the southwest, Coma Berenices in the northwest, Ursa Major in the northeast, or Leo in the southeast, all groups which, when once located, cannot be mistaken for anything else; and then to stir in between them with the map as our guide. It is worth noting, however, that the star Zeta Puppi (Alpha M31), which shows the series of hydrogen lines of which we speak (described on page 110).

NIGHT SKY - FEBRUARY AND MARCH.

lengths of the lines of such series have been given by Rydberg, who uses equations of the form

$$\frac{1}{\lambda} = \frac{N}{m^2} - \frac{N'}{(m + \mu)^2}$$

in which  $m$  has the values 2, 3, 4, etc.,  $N$  and  $N'$  are constants different for each series of lines, and  $N$  is a "fundamental number," which is the same for all series and all elements, and may depend on some unexplained peculiarity of atomic structure.

The constant  $\mu$  is usually not a whole number, but is less than unity. If we make it exactly unity, and give  $\mu$  a proper value, the formula reduces to that for the "balance series" of hydrogen.

When the equations for the different series are written in this way a remarkable connection appears between the "principal" and "sharp" series. In fact, the equations for the two may be combined in the formula

$$\frac{1}{\lambda} = \frac{N}{(m + \mu)^2} - \frac{N'}{(m + \mu + 1)^2}$$

(considering for simplicity a series of single lines). Here  $\mu$  and  $\mu + 1$  are two constants. If we let  $\mu = 1$ , and give  $N$  the values 1, 2, 3, 4, we get the positions of the lines of the principal series, while if we let  $\mu = 1$ , and make  $\mu = 2, 3, 4$ , etc., we get (after changing signs) the wave-lengths of the sharp series. It is obvious that if we know the lines of one of these series we can work out the formula, and then calculate where the lines of the other series ought to be.

This relation has been tested on several elements showing such series in their spectra, and found to be generally true (though not perfectly accurate, pre-

# The Fourth Award of the Scientific American Medal

## An Oxygen Fed and Driven Device for Artificial Respiration

THE fourth bestowal of the Scientific American Medal was made with the usual awe by the Jury of Awards of the American Museum of Natural History on January 23rd at a largely attended meeting held in the auditorium of the United Engineering Society's building. Before the meeting, at which four medals were awarded, a dinner was served in the Bowler W. Raymond room, which was attended by ninety distinguished guests, including Dr. and Mrs. Andrew Carnegie, Mrs. Thomas A. Edison, and many other persons well known in humanitarian movements.

President Arthur Williams presided at the meeting. The Scientific American Medal was awarded to the Dräger Oxygen Apparatus Company of Pittsburgh, Pa., and Lübeck, Germany. The presentation address was made by Dr. Frederick H. Hutton.

In part Prof. Hutton said: "It is the pleasant and precious privilege of the Museum of Natural History to be the representative of the community and of you all in recognizing the splendid quality of altruistic service. It is the dream and in spirit of the Museum, that on some day the trustees may discharge this duty in the own building built and operated by the State, which has delegated its duties to it, and by the municipality which benefits principally by its activities, as well as by the generous co-operation of the individuals who recognize the opportunity. But, at present, we do this pleasant duty in a hall belonging to someone else, and the medals which we award are the gifts of individuals or corporations who have been enlightened to see that by endorsing such a medal they were fostering and fanning the spirit of unswerving and unselfish service for industrial mankind.

"These medals are four in number. They will first be listed and the recipient named, with the reasons for the action taken, and then the designated representative will be asked to come to the platform, that the medals may be handed to them in person.

"The medals are listed in chronological order.

"The Scientific American Gold Medal must be for some safety or life-saving device, invented within a recent of three years, and exhibited in the Museum's collection. The device selected for 1912 in this class is the Pulmotor.

"The phenomenon of respiration are combinations of mechanical action and chemical reactions. The presence of poison in the blood-current stimulates the brain cells, which automatically start up the muscles of diaphragm and thorax, whereby the chest cavity is expanded and air flows in to react upon the blood exposed to such oxygenating action. If the poison is excessive, if the lung cavity is filled with water, or if the chemical compound in the blood is stable or unbreakable, respiration does not take place, the nerve centers are paralyzed and death results. If the nerve centers are paralyzed by poisonous electrical action, respiration ceases.

"I give herewith a description of the device in greater detail than was possible in an address.

"The Pulmotor, for which the specific award of the Scientific American Medal was made, is an oxygen-fed device designed primarily to induce respiration by artificial means in persons overcome by noxious gases, electric shock, the apparently drowned, or in any other cases where the breathing of the patient has been seriously impaired or stopped entirely, but where there still remains a slight heart action. The object of the apparatus is to inflate and deflate the lungs in a rhythmic manner, and the pulmonary and electric mechanisms are so timed that normal number of respirations per minute is obtained. Its motive power is an oxygen cylinder supplying this apparatus a pressure of 120 lb. per sq. in. It delivers a 50 per cent. mixture of air and oxygen to the patient for every breath. Should it then become necessary to stop the oxygen supply, the patient may be supplied with a tank of fresh air. The great advantage of

The pulmotor in its case ready for use.

The pulmotor is of great help in the hospitals in cases where persons are overcome by noxious gases or fumes.

The pulmotor is brought to the point of rescue by an automobile, and the motorman is saved from the effects of electric shock.

artificial respiration is found in that it forces large amounts of oxygenated air into the lungs than is possible by the ordinary methods of artificial respiration, and it makes it possible, through its automatic mechanical action, to keep up the work for long periods. The Pulmotor is so adjusted that it will force air into the lungs until it reaches a pressure of about 5/10 pounds, so that the same result is thus mechanically obtained as forced breathing in a healthy conscious man. Therefore when the three pounds pressure is reached the apparatus reverses mechanically until it obtains a negative pressure of three pounds, so that all of the deoxygenated air is thrown out, leaving the lungs empty and free for a new supply. This pressure is particularly valuable in cases of gas poisoning because five atmospheres pressure will maintain oxygen in the blood fluid even after the blood cells have been so damaged by carbon monoxide that they are no longer able to maintain life but life is maintained in this artificial means until the hemoglobin of the red blood cells which normally carries the oxygen can recover itself. The Pulmotor in its case weighs about fifty pounds, so that it can be carried about readily in automobiles, fire trucks or ambulances. The wooden case contains two entire separate pieces of apparatus: an oxygen inhalation apparatus for ordinary oxygen inhalation (mounted on the lid of the case for use after the case has been restored) and the special apparatus for artificial respiration which is housed in the case itself. The two pieces of apparatus have in common the oxygen cylinder and the pressure-reducing valve and either of them can be set in operation immediately by turning a suitable screw down lever to the right or left upon the reducing valve. The steel oxygen cylinder is closed by a valve which can be opened by a turn of the thumb and finger. The cylinder contains 113½ cubic feet of pure oxygen. The oxygen passes from the reducing valve to an injector which has the property of drawing in a large volume of air with a very small force of suction, and propelling that air forward with equal force through the flexible tube in front of the injector. This suction and delivery injector, therefore, serves as a motor alternately filling the lungs by pressure and emptying them by suction. The most striking part of the Pulmotor is a small flexible accordion bellows which effects the automatic reversal of the apparatus from suction to delivery and vice versa when necessary. The bellows is connected with the air tubes. During inflation the same pressure obtains in the bellows as in the lungs and as soon as the latter are filled the bellows becomes inflated and in moving forward causes the valve to be automatically reversed into position for suction. The operation is now reversed and as soon as the lungs have been emptied the bellows contracts and automatically reverses the valve again into position for inflating—and so on. From what has been stated it will be clear that the respiratory rhythm of the apparatus readily adapts itself automatically to the capacity of the lungs in every case. The rhythm will be slow when the lungs are emphysematous, and faster with those of smaller dimensions. The apparatus performs all these functions without any assistance from the hands, so that the operator can turn his attention to an important thing, namely, keeping the wind pipe open and closing the mouth. The essential condition for the success of artificial respiration is the provision of two flexible breathing tubes on the mask. One of these tubes serves exclusively for the supply of pure air and oxygen while the slight inhalation apparatus can be called into play and as already stated, this portion of the apparatus is carried on the lid.

Some of the results obtained by the use of the Pulmotor are most remarkable. On February 12th 1912, several Pulmotors were ordered for installation at as many Relyea properties. Up to January 23rd 1913, twenty-four lives had been saved in the twenty-three instances, and a number of cases had been reported since.

## RECENTLY PATENTED INVENTIONS

These columns are open to all patentees. The notices are inserted by special arrangement with the inventors. Terms on application to the Advertising Department of the Scientific American.

## Pertaining to Apparel.

**GARMENT HANGER.**—J. K. Kline, care of Midway Mfg. Co., 175 Center St., New York, N. Y. This invention provides a hanger for supporting coats, vests, suits, trousers, shirt waists and other garments, and is adapted to be folded into a comparatively small space for convenient carrying in a vest pocket or storing in a traveling bag or other similar traveling article.

**HOCKEYCAP.**—T. Dwyer and J. F. Dwyer, Flatbush, N. Y. This invention is intended more particularly for embodiment in four-in-hand and like sports in the form of a continuous band or strip of a length to constitute a neck hood, and to be formed into a knot, having depending flaps or ends.

**BUCKLE.**—W. J. Payne, 11 N. 4th St., Chattanooga, Tenn. The invention has for its object the provision of a buckle device for a buckle especially designed for ladies belts, which can be attached to delicate fabrics with-

out causing them to wear toward the planes over two rollers mounted substantially at the same height as the end of the short arm.

## Electrical Devices.

**SYSTEM OF ELECTRICAL SUPPLY.**—W. C. Woodcock, care of Packard Electric Co., Warrenton, Ore. The principal object of this invention is to provide a series lighting circuit which is inductively controlled, the system being arranged so that the load may be altered without the system remaining substantially constant. The system is inductively controlled through the medium of a suitable transformer, together with reactances in the primary and secondary of the transformer circuit.

**ELECTRIC SWITCH.**—C. E. Knowlton, 215 W. 3rd St., Rochester, Minn. The switch shown in the accompanying drawing is of the button type; the buttons being arranged

ELECTRIC SWITCH

to tilt on suitable journals so as to come up over the double knife switch. The switch is self-closing, and when the current is off, the button is held in the open position by a spring. To open the switch the button is lifted back flush with the plate.

**PREMIUM INDICATOR.**—J. H. Wilcox, 1115 Mt. Vernon St., Oakland, Cal. This invention is more particularly directed to a device especially adapted for rating the excellence of produce of a tomato or blanding caps. The principal object is to provide a testing

PREMIUM INDICATOR

device whereby the explosive pressure in pounds exerted by a blasting cap or electric detonator will be directly indicated. It provides a testing device of substantial construction whereby the force exerted when a blasting cap or electric detonator explodes may be indicated directly on a pressure gauge. The measuring shows in action the operative rating of the device, together with a blasting cap or a detonator suitably held in position thereto and in direct with a battery.

## Of Interest to Farmers.

**MOWING MACHINE.**—J. A. Brownson, 32 Greenwich St., New York, N. Y. This machine is self-propelled and is provided with new and useful means for controlling the cutter bar

MOWING MACHINE

frame. The principal object is to provide a machine having a plurality of bars between the frame carrying the bars, and more or less loosely constructed whereby these bars may be raised and lowered in position in the ground when the machine is in use. A further object is to provide means for moving the

cutter bar driving mechanism out of operative position in order to permit the machine to be run over the ground with the bars inactive. The illustration herewith represents the machine in a side view.

**AUTOMATIC MILK CAN FILLER.**—J. W. Mulvan, care of G. A. Thacher, Chaska, Minn. The principal object of this invention is to provide a means for filling milk cans, bottles, etc. in succession the milk flowing into the first of a series of cans, and when the first is filled the milk is automatically shut off from this can and permitted to flow into the next can of the series, and so on successively to the end of the series of cans.

**GARDEN RAKE.**—James Dickerson, Box 113, Underhill, Ontario, Can. The principal object of the invention illustrated herewith is to provide an implement adapted to receive

GARDEN RAKE

a temporary device to shatter or agitate the ground through which it is drawn. This is effected by causing the stem of the rake with a wire which is drawn. The wire is pulled through the ground surface to loosen the earth surrounding plants.

**HAIR RAY EVAPORATOR.**—G. H. Runk, Fairfield, Vt. In this invention a use is made of a heater, an fan adjacent to the heater and having a turbine passage extending from one side of the fan to the front and back to the fan at the other side, light connections connecting the heater with the fan at both ends and at the rear of the fan means for closing, if necessary, connection and strap outside on the fan adjacent to the inlet.

**General Interest.**  
**MINUTE INDICATOR.**—R. E. Leland, care of Sanford Novelty Company, Sanford, Me. A spoonholder is provided in the present invention which may be conveniently attached to the garment of the person and which provides a not only a receptacle for a spoon, but a

SPOON HOLDER

delivery guide for the thread drawn from the spoon and receptacle. The device is of such form and may be readily kept in a work basket when out of service.

**WINDOW.**—R. R. Hartwood, 210 W. 114th St., New York, N. Y. This invention relates to windows having sills mounted to slide up and down, and means provided on the sills to admit of turning the sills on the sills. The purpose is to provide a window arranged to permit of conveniently turning the sills with a view to allow cleaning of

WINDOW

the outer face of the sills from the inside of the room. For this, use is made of a wire frame having perforating sills of fixed and movable sections and cross-bars carrying the sections and mounted to swing on the sills of the window frame to allow of turning the sills on their sills at the time the movable sections and their sills are swung down to the outermost position. The operating shows an inner free view of the window

**BOOK LINE GUIDE RULER.**—C. H. Gould, care of J. B. Deane & Co., Tampa, Fla. This invention provides a ruler adapted for adjustment of dislaid and separate book sections, and is especially adapted to be used on continuous line across the two half bars thereof.

**HOSE REPAIRING DEVICE.**—R. E. O'Brien, care of J. B. Deane & Co., Tampa, Fla. This device with a clip to which the tug straps may be secured the clips being the ends of the hose, the device is used in the hose having forwardly extending shoulders disposed in bearing openings in the swivel.

HOSE REPAIRING DEVICE

and lateral arms disposed in the slots on the swivel tree so that the locking slide is provided for engaging the lock. The clip will hold the clip in position on the rear of the swivel tree until the locking slide is drawn back, when the clip will pivot on its shoulders, and the inner end of the clip be thrown free from the swivel tree. The invention shows an enlarged sectional view of the end of one of the swivel trees, with the locking slide drawn back to free the clip.

**ANTHELMINTIC TREATMENT OF PITH PILLS.**—P. Dwyer, 1010 W. 114th St., New York, N. Y. The invention provides a protection for the mouth, use of a larynx, swelling tubes and the like, and arrange to prevent to the user a thoroughly disinfected and aseptically sealed tray, which is adapted over the exterior end of the mouthpiece with a view to prevent contamination of the mouthpiece and to protect the user against transmissible diseases.

**THROW.**—P. Dwyer, 1010 W. 114th St., New York, N. Y. This invention is designed for the relief of sufferers of hernia and is so constructed that it will hold any rupture, no matter how old, obstinate or recalcitrant under all conditions, and without causing any inconvenience to the user.

**DAIRY.**—J. H. W. 1010 W. 114th St., New York, N. Y. The object here is to provide a means for the treatment of concrete or other suitable material which will possess the maximum amount of strength and stability with the least amount of material. A further object is to provide a structure in which the said thrust is introduced into a compound, retaining the thrust downward.

**THROW.**—P. Dwyer, 1010 W. 114th St., New York, N. Y. The object of the invention is to provide a means for the treatment of the spine in a bar which forms the base part of a right frame secured to the body by a perfectly fitted strap. The frame is so formed that one side thereof projects in a

THROW FOR HERNIA

direction at right angles to the general direction of the bar on which the bars raising pads are mounted and is arranged so that the said spine portion will accommodate an abdominal pad which acting against the body will give a leverage action for properly holding the hernia supporting pads to their work. A perspective view of the device as applied to an abdominal rupture is shown in the accompanying illustration.

**REVOLVING CARD RINGS.**—J. A. Macdonald, 147 W. 114th St., New York, N. Y. The object here is to provide a revolving card as constructed that the display cards may be readily disengaged and replaced. The invention is adapted to provide a stand more particularly for use in display cards such as in the case of a revolving card display. The application Serial No. 601,075 filed November 10, 1911.

## Hardware and Tools.

**COMBINATION LOCK.**—J. K. Kline, care of J. B. Deane & Co., Tampa, Fla. In this case

# \$2,000,000 Buried

By R. E. Olds, Designer

In Reo the Fifth, we bury at least \$2,000,000 a year where few men ever see it.

That's somewhere about \$200 per car.

It is not merely hidden. It is spent on extremes—on over-caution, some say.

And it may take months—even years, sometimes—to discover all that this buried money buys.

## Not Charged to You

This hidden cost is not added to your bill. The price of this car will show that.

We save it all—and more besides—by unusual factory economies.

In one way alone—by building only one model—we save about 20 per cent.

By not changing models in any radical way we save a great deal more. That comes from right designing.

We build all our own parts.

And our factory efficiency is so well known that engineers from everywhere come here to inspect it. Magazine articles have been written about it.

That's the whole reason why a car like this can be sold for \$1,095.

## You Get Twice What You See

In Reo the Fifth you see a beautiful car—roomy and rich and impressive.

The body is finished in 17 coats. The upholstery is luxurious. Every detail shows the final touch.

Flush electric dash lights instead of the side lamps. Nickel trimmings, even under the hood.

But don't judge a car by these showy externals. That's mere body-building—easy, usual and cheap.

## What to Consider

The chief points in a car are endurance and safety. And those depend largely on steel.

So I have steel for each part made to my formula, based on

26 years of experience. Then I analyze each part—analyze it twice—to prove its accord with those formulas.

Then I give each important part vast overcapacity. I employ the same tests as are generally used for a 45 h.p. engine.

Instead of steel castings, which cost half as much, I use in this car 190 drop forgings. Thus hidden flaws are avoided.

## Roller Bearings

I might say Timken bearings and use only two. But I use them for endurance, not claims.

There are no ball bearings in Reo the Fifth, save in the clutch and fan. There are 15 roller bearings. The usual ball bearings would cost one-fifth as much.

I use a \$75 magnet.

I use a centrifugal pump.

My carburetor is double heated—with hot air and hot water. That saves a world of trouble.

I use 14-inch brake drums. I use 2-inch, 7 h.p. springs.

## Tires 34 x 4

This car is vastly overbuilt, and tires, as you know, are expensive.

I spend on tires about \$60 per car more than other experts think necessary. But nobody doubts that I save my users from three to five times as much.

Then my tests and inspections are immensely expensive. I test

my gears in a crushing machine with 50 tons' capacity. I test my springs in another machine, for 100,000 vibrations.

Each engine is tested 20 hours on blocks, and 28 hours in the chassis. I use three 10-hour tests which are very unusual.

Each car in the making gets a thousand inspections.

Parts are ground over and over to get utter exactness. And our output is limited to 50 cars daily, so no man is ever rushed.

## Ideal Center Control

The leading cars, as you know, have come to left side drive. Also to center control.

But center control, in Reo the Fifth, doesn't mean the old side levers moved to the middle.

Our center control is a sort of cane handle. All the gear shifting is done by moving the handle only three inches in each of four directions. It's as easy and simple as moving the spark lever.

No reaching, no levers in the way. Both brakes are operated by foot pedals. Thus both front doors are clear.

The driver sits on the left hand side, close to the car's harness. Yet his right hand controls the car.

This exclusive feature costs nothing extra. But if it cost \$100 men would pay it, I believe.

## My Idea of a Car

This is my idea of an honest car. It is the final result of 26 years spent in building cars.

I would not buy a car built otherwise myself. So I shall never buy one.

My success is due to these extreme ideas. No are my legions of friends among motor car users. This year I am seeking for 10,000 more such friends.

A thousand dealers handle Reo the Fifth. Write for our 1913 catalog and we'll give you the address of the nearest.

**Reo the Fifth**  
The 1913 Series  
**\$1,095**

30-35 Horsepower  
Wheelbase—113 inches  
Track—34 1/2 inches  
Center Control  
14 Roller Bearings  
Dynamometer Run

## Success of the County Agricultural Bureaus

By Charles M. Correll

THAT the farmers of this country are awakening to the necessity of employing modern, business-like methods in conducting their farms if they want to secure the best results, is becoming more apparent every day. The rapidity with which County Agricultural Bureaus are being formed all over the United States is the best proof in the world that the men who till the soil are beginning to realize that antiquated methods and old-fashioned ideas have no more place on the farm than in any other field of work. There are now about 100 County Farm Bureaus in active operation in the different States, as many more have organized, but are not yet employing county agents, while the total number of counties applying for information with a view to establishing agricultural associations is 603.

It was two years ago that the Council of Grain Exchange conceived the idea of placing an agricultural expert and adviser to the farmers in every county in the United States. The Crop Improvement Committee, with Bert Hall as its secretary, was then formed, and the raising of a national fund to carry on the work was started. This fund received a stimulus last spring in the shape of a million dollar donation from Julius Baerwald of Chicago, who has set aside this sum, one thousand dollars of which is to go to each of the first thousand counties that are willing to cooperate in the work.

Two of the first counties to avail themselves of this offer were Kankakee County, Illinois, and Pettis County, Missouri. While the two counties proceeded along similar lines in forming their associations, each has worked out certain individual details of peculiar advantage to itself. The Crop Improvement Committee itself takes no active part in the organization of these Farm Bureaus, each county being left free to act as it sees fit. The committee simply recommends a line of procedure which will enable it and the county committee to make a satisfactory agreement.

The farmers and business men of Kankakee County were quickly impressed with the general plan of the Crop Improvement Committee's plan, and determined to give the notable honor of being the first county in the United States to qualify for one of the thousand-dollar donations. A few far-sighted men behind the scheme had a dream of doubling crop production, of property resulting from these bounteous yields that should make Kankakee County the best place in the world to live in. The idea caught the imagination of the people of Kankakee County. Farmers, bankers, millers, manufacturers, joined hands to raise the money needed to put the bureau on a permanent basis and carry out the other conditions prescribed by the Crop Improvement Committee. In less than two weeks more than \$10,000 was raised and the organization, known as the Kankakee County Soil and Crop Improvement Association, was incorporated with a capital stock of \$50,000.

Prof. John R. Collier, of the Agricultural Department of the University of Illinois, was chosen as the association's expert. His duties are to advise the farmers, individually and collectively, as to the best methods of cultivating their farms, to point out the troubles and prescribe the remedies, to organize clubs, associations, etc., to give practical farm demonstrations in crop rotation, soil building, farm management. In short, he has been employed by the association to show the farmers how to get more from the same amount of land and how to make what they produce of better quality.

Prof. Collier proposes to visit every farm in the county, and to have a complete history of each, together with a soil analysis. As there are about 2,000 farms in the county it will require some time to complete this task, and he is taking up the farms of the members of the association first.

## PATENT ATTORNEYS

## PATENTS

If you have an invention which you wish to have you can write fully and freely to Munns & Co. and we will advise you without any obligation. Please send a description of a model of your invention and a statement of the device, explaining its operation.

All communications are strictly confidential. Our vast practice, extending over a period of more than sixty years, enables us to secure you an address in regard to patentable inventions without expense to the client. Our Head Office on Patents is at London, England. This office has many methods, terms, etc., in regard to PATENTS, TRADE MARKS, FOREIGN PATENTS, etc.

All patents secured through us are described according to the practices of the SCIENTIFIC AMERICAN.

361 Broadway, New York

The county authorities have contributed the sum, next free, of four commodious rooms in Kankakee's new half million dollar county building as the association's headquarters. There are, in addition to Prof. Collier's private office, a large meeting room, a library containing several hundred books of agriculture, a rest room for the farmers' wives, and a large play ground for the farmers' children. A completely equipped agricultural laboratory has also been established in the Kankakee High School.

As soon as the association had been formed, work was started to form from ten to fifteen co-operators in each township in the county. These co-operators send regular reports of the progress of crop improvement in the different townships to Prof. Collier. Arrangements are now being made with the National Government whereby domestic science will be made part of the county farm bureau, the work to be in charge of a competent woman who shall make a study of home life throughout the county, and act as adviser to the farmers' wives, as Prof. Collier is doing with the farmers about their fields.

Usually the soil expert spends the large part of half a day on each farm, going over each field and giving advice as to its management. Then there are numerous emergency calls to be attended to. One day it is a man who wants to know what to do for corn worms, the next it is a man who wants to know why his rice straw falls down.

Another plan of the Kankakee farm bureau is the formation of a seed testing association, which will make it possible to insure clean tested seeds for every farmer in the county. The idea is to erect a seed house in Kankakee, equipped with seed cleaning and seed grading machinery of the most approved type, that no seed be accepted here except after ground by members of the association under its rules. In this way it is urged that the association would gain national prominence, second to none on earth, on account of the superiority of its seed. The estimate is made that clean and tested seed alone will add half a million dollars to the crop value of the county.

The seed testing and seed selection work has been given a stimulus by getting the school children interested in it. By what is called the "Rag Rag Tow," a ten-year-old boy or girl can quickly ascertain whether seed is good, bad or in different. It is the plan of the Kankakee County farm bureau to widen the scope of this work among the children and put the little ones in competition with their fathers and older brothers.

The organization of a farm bureau in Pettis County, Missouri was due to the Hoosiers' Club of Hedalia. Early in the history of the club its members realized that anything that could be done for the practical benefit of the county would redound to the benefit of the city, and with that idea in mind they promoted the building of rock roads, better livestock, more extensive dairying and improved methods of marketing.

Hedalia is a city of about 21,000, and Pettis is regarded as one of the best counties in the State, having approximately 1,000 farmers whose lands vary in worth from \$80 to \$200 an acre. A close scrutiny of federal and State crop statistics, however, compelled the humiliating consciousness that Pettis County crop yields, particularly of corn and wheat, spoke much too low. Why? Something was wrong. What was the cause of this condition and how could it be remedied?

These questions confronted the club, and it decided that the farmers of the county would have to change their methods or quit farming. The conclusions drawn, after careful study, were that what the county needed and should have was the services of an expert, practical farm adviser.

Along with these the State Board of Agriculture, gave Pettis County a special tax incentive date at Hedalia, with the intention of the members. After having been

## A Princely Coupe — The Cadillac

Aside from the fact that it is a Cadillac with all that the name implies, we believe we are justified in describing this as the most sumptuous car of its type ever built.

You may key your expectations as high as you please. There is no danger of disappointment.

Consider first, convenience

You enter the Coupe at either side.

Your foot presses a lever and the engine starts.

You press a button and the electric lamps are lighted

You are ready—immediately

And you ride in such luxury that the imagination cannot surpass it

By luxury we mean both motion and the "creature-comforts."

Let your critical eye turn where it will—

there is nothing that is not super-excellent

You literally cannot conceive a more princely equipage

It is an every-day-in-the-year car, always comfortable, winter or summer, rain or shine

Or, if you wish, with an additional body you may transform it into an open car

And, it is a Cadillac, the Prince of Coupes.

The price is \$2,500 F O B Detroit.

CADILLAC MOTOR CAR CO.,

Detroit, Mich.

Interior Arrangement

The illustration shows the interior arrangement of the Cadillac Coupe. The driver's seat is about 8 inches forward of the seat next to it. This gives greater thigh room. To allow entrance from the driving side, the driver's seat folds back. There is ample room on the side for two passengers beside the driver, and the fourth passenger occupies the front seat. The front and rear seats are upholstered in leather and the rear seat is upholstered in the same material. The four side windows are removable, and they are specially made to be rain-proof, whether up or down.

### Coming Army Aeroplanes

**By C. H. Clardy**

**A**FTER all necessary expenses are paid, and the present aeroplanes of the army provided with needed repairs, etc., the Signal Corps will have about \$35,000 of the 1913 appropriation left for the purchase of new aeroplanes. This sum will buy not more than four, and probably not more than three new machines.

The past four years have been largely experimental so far as practical aviation in the army is concerned. The Signal Office, having the work in charge has been more concerned with the development of what was needed with the ascertaining of the possibilities of aviation in the army. The first step in the making of an aeronautical arm of the service fitted for offensive work. Out of the many experiments, the countless flights, the many changes made in machines, certain very definite plans have come into being and certain well defined ideas have grown. These plans and ideas will, in all probability be incorporated in the new regulations for the army's aeroplanes, which will soon be published, and on which aeroplane makers will be asked to submit bids.

Definite announcements cannot be made as to the contents of these specifications but it is very probable that the first and perhaps the most far-reaching of the new requirements will provide that no aeroplane with a motor developing less than 80 horse-power will be considered. In other words, it is no longer the minimum power and the lightest motor which is desired but the lightest motor which will develop sufficient power to provide for emergencies and permit both speed and carrying ability.

The aeroplanes, which manufacturers will be invited to bid upon, will probably be required to possess stream line enclosed bodies, and this specification will be applied as rigorously to the biplane as to the monoplane. Both for the protection of the aviator and observer from wind and cold and in order to reduce head resistance the enclosed type of body is now thought to be advisable.

Pictures of the Curtiss flying boat purchased by the Signal Corps for army experiments show something of what an enclosed body looks like. The flying boat, however, has a larger and clumsier enclosure than is wanted on the new aeroplane, which are not required to be capable of running upon the water.

A revolutionary as anything in army flying machines anywhere. In the world, will be the requirement that the new machines be armored. Experiments are now being made to determine the minimum thickness and weight of the finest laminated chrome steel armor, designed for aeroplanes use. This chrome steel armor must be thick enough to protect the aviator from rifle fire at a height of two thousand feet or a range of two thousand feet at an angle up to forty five degrees, yet thin enough not to impede the carrying capacity of the craft.

## WASTE EFFORT

**Look around your office—are your clerks wasting your profits doing work by hand that can be done in a fraction of the time with a machine—**

# Addressograph

TRADE MARK  
PRINTS FROM TYPE

A clerk busily engaged pushing a pen may be doing brain work or monotonous drudgery—you can't tell. Dig deeper—and out what your clerks are doing—you are buying brain power, not hand power, from them. And they don't like to write and rewrite names and addresses by hand any more than you will want to pay for doing this work by hand when you find out how much it costs. Your clerks are worth about 18¢ a day to you when an error is made.

Your clerks are worth about 10¢ a day to you while so occupied. Your best clerk can write 800 to 1,000 addresses per day. An office boy, with the ADDRESSOGRAPH, can print an equal number in less than half an hour. And the ADDRESSOGRAPH can be used not only for addressing envelopes, circulars, letters, etc., but also for filling customers' names in on statements and bills—printing employees' names on time clock cards, pay envelopes, pay checks, piece work tickets, pay-roll sheets and other forms—addressing shipping tags, dividend checks, notices and, in fact, everything frequently addressed to a regular list of names.

## Let Us Show You How To Eliminate Waste Effort In Your Office

Tell us about the list of names you frequently address. Send us samples of your forms. Tell us how many you have on your list. Then we can prove to you in dollars and cents just how profitable the ADDRESSOGRAPH would prove in your office.

[illegible]

THE SPELL OF ENGLAND By Julia de  
Wolf Addison Boston L C Page &  
Co 1912 8vo 433 pp illustrated  
Price \$2.50 net

The *Spain of England* is one of the best volumes of The *Spain Series* which is anyone's guess. Possibly the author's childhood in Spain has helped him to give his book a personal treatment. But this must of course have been supplemented by mature observation and judgment before an intimate a description covering all the important aspects of the country could be compiled with humor as well as with care. Indeed, refined characteristic humor has always a charm of its own and there is never too much of it. Here it is used to good advantage and the author's own created lightly lovely yet lovingly and the result is a very readable and instructive work.

The illustrations from special photographs are always a charming feature of the series and this one is no exception. The illustrations are in color of course to the standard. The frontispiece in colors of Lamas a lower Warlock a title is particularly faithful and beautiful a special credit.

ROBERT PAPER AND BUILDING BY LOGAN  
WALTON COMPANY 1912 16mo 263  
pp illustrated Price 75 cents net

Mr. Page is director of United States Office of Public Roads, president American Association for Highway Improvement, and a member of the American Society of Civil Engineers. With all these qualifications he should be able to impart some very instructive information on a topic of the most vital importance to the country at large. And within the scope of so compact a work Mr. Page has fulfilled all expectations. He truthfully says at the beginning that road building is an art, based upon a science. A deep knowledge of any

art or any science can be acquired only at the expense of years of study and practical application. But the farmer and his country gentlemen may find even a superficial knowledge provided him grounded in true principle most useful and beneficial. And it is with this particular in view that the author writes. Learning is everywhere; it is in the soil beneath our feet from an early chapter.

This is / it will tell you / what sort of gravel broken stone and merradum Maintenance and repair renders the attention worthy of so important a branch of the soil men and a paper on the construction of culverts and bridges concludes a most useful and practical work

## Electricity

**Wireless to Germany.**—The first wireless message sent direct from the United States to Germany was sent on January 17th from Sayville, Long Island and received at the Nauen tower near Berlin, Germany. The distance is about 3,000 miles. Hence it has been necessary to relay wireless messages to Berlin and other points on the European continent.

**Electrification of London Railways.**—The London and Northwestern and the London and Southwestern railway companies are about to carry out an important electrification scheme involving over 100 miles of track in the metropolis. Direct current at 600 volts will be employed, with third and fourth rails, the trains being operated by the multiple-unit system. The scheme includes connection with the entire underground railway system of London.

**Large Electric Clock.**—To advertise the Boston Edison Company, a large electric sign has been set up in that city measuring over 44 feet in width by 80½ in height. The sign contains a clock with the dial 34 feet in diameter, at each side of which are columns studded with electric lamps. The minute hand of the clock is 18½ feet long and weighs 488 pounds; the hour hand is 14 feet 4 inches long, weighing 388 pounds. The total weight of the structure is 15 tons. Altogether there are 5,000 lamps used in the sign.

**Careless Destruction of Fireproof Cables.**—In a very serious fire which recently occurred in an English electric generating station certain cables, made with an outside covering of fireproof braid, were destroyed by fire in a remarkable way. The origin of the fire was a comparatively small blaze that had been started by an accident to a short circuit. Although this first fire was promptly extinguished, it means that the short circuit had enormously overloaded the first-mentioned cables, to the point of losing their strain-proof cover and so on. The reduction of the core near the breaking, exposing the rubber insulation underneath to the air so that it burst into flame.

**Electrically-driven Ship Machinery.**—A new English passenger and freight ship is fitted with electric motor-driven auxiliary steam engines, two engines, at each end, and two warping engines—supplied with current from a central electric generating plant. The machinery was especially designed for the rapid and quiet handling of cargo, and the electric drive gives a greater overall efficiency than steam equipment. At the same time, there is a single large unit in which the steam is used very economically compared to the waste in the ordinary "donkey engine." Furthermore, the losses in steam pipes leading to each engine from the boilers, by radiation and leakage, are eliminated, and the engine room itself has to be "warmed up," but is always ready to run.

**Wireless Telegraphy Without Ground Connection.**—The new wireless telegraph station at Fremantle, Australia, which has just opened communication with Sydney, across the 2,500 mile width of the continent of Australia, is operated without a ground connection in the ordinary sense. On account of the extreme dryness of the sandy soil at Fremantle (there is absolutely no rain during the six or seven summer months, and the underground water is at a great depth below the surface) a satisfactory ground connection could not be established readily. Accordingly an insulated counterpoise is employed instead, constituting the lower element of the electrically vibrating circuit of which the antenna is the upper element. The counterpoise is a system of about hundred insulated wires radiating out from the antenna tower and joined and supported by three concentric circles of wire. The web thus formed is supported on poles which are higher toward the center and lower at the outer edge, making a flattened dome. This counterpoise system gives an open shape to the vibratory circuit, insuring satisfactory radiation and a more outward reflection of the waves from the counterpoise.

**British Electric Welding Practices.**—A recent paper on electric welding deals with resistance welding, in which the heat is generated just at the spot where it is required, also give true welding, every other process, electrical or other, involving the fusing of the two metals together. With an alternating current transformer the required voltage varies according to the size and nature of the work—from 80 amperes for a small wire welder up to 75,000 amperes on a large trolley welder. Resistance welding is simple, accurate, reliable, speedy, and does not result in quantity production. On mild steels, for example, may be made at the rate of 10 to 15 per minute. A wire welder can average 525 times of different size per week, and spot welders can make 35,000 welds per week. The thermal efficiency of electric welding is as high as 75 per cent, and the mechanical strength of the weld is 98 to 100 per cent, which compares favorably with hand welding. Iron and mild steel can be welded very satisfactorily, though high-carbon steel (0.8 per cent carbon) does not seem to give good results. Copper and its alloys, nickel, aluminum, brass, etc., can be welded, but these do not lend themselves to spot welding and, indeed, are but welded.

## Science

**The Usual Turbulence of the Atmosphere,** which began last June and appears to have continued through the summer and autumn, is to be made the subject of an investigation by the U. S. Weather Bureau. A circular requesting notes of any observations that have been made of the phenomenon has been issued by the bureau to a number of astronomers and meteorologists.

A Prize of 2,000 Marks has been awarded by the German Meteorological Society to Mr. Ernst Gold, of the British Meteorological Office, for the best discussion of the results of the international investigations of the upper air. Mr. Gold, who is only 41 years old, is probably the highest English authority on dynamic meteorology, and is one of the brilliant group of Cambridge men who have given the British meteorological service its present conspicuous position in the scientific world.

**The Sources of the Congo.**—A telegram from Sekania, Belgian Congo, announces that the German officer, Louis Grütz, who in 1900 crossed Africa in a motor-boat, has now accomplished the same feat by motor-boat. The most important geographical result of the enterprise appears to be the discovery that there is a continuous waterway from the source of the Chambou, in northern Rhodesia, to the River Congo, which is thus proved to be the longest river in Africa.

**Sodium and the Series of Radio-active Elements.**—In a paper read at the meeting of the Royal Society, Dr. Rutherford presents evidence that sodium belongs to a radio-active series of elements "Geophysics," he asserts us "furnishes two distinct lines of evidence which favor the hypothesis that sodium belongs to a series of radio-active elements. The first is based on the age of the sodium as determined by radio-active data and by the accumulation of sodium in the ocean. The second is based on the relative accumulation in the ocean of sodium compared to chlorine, taken in connection with the relative annual output of these two elements from the rivers."

**New Radio-telegraphic Stations in the Arctic.**—In view of the attempts now under way to accomplish the North Pole passage and the much-discussed question of establishing regular trade-routes by water to the Arctic coast of Siberia, great interest will be felt in the fact that the Russian government is installing radio-telegraphic stations at the entrances to the Sea of Kara, viz. at Vauchok Island, Yuzor Strait and Monrovia. (Former vessels which were wrecked in the Kara Sea will be able to communicate with Vardø or Archangel until they are advised by wireless that the passages are free from ice.)

**The Plants, Animals and Birds of the Bible** have been made the subject of a special exhibition in the Natural History Museum, London, in honor of the late Sir David Stevenson, and the trustees of the museum have published an interesting "Guide" to the collection. Among the striking bits of information contained in this work are the following: The common fowl is not mentioned in the Old Testament, and was probably introduced into Palestine after the Roman conquest. The unicorn of the Old Testament was probably the Syrian aurochs, now extinct. That the "behemot" was not the hippopotamus is made probable by the fact that there is no record of the latter animal in Syria or Palestine in historical times. The "laver" of the Bible were darned grasses, whose seeds are poisonous, the "rose" was probably the narcissus, while the "lily" was the poppy anemone.

**The Present Progress of Antismogism** is discussed by Dr. J. Maury, president of the International Commission on Solar Radiation, in the recently published report of the last meeting of that organization held at Vienna in September, 1912. For years measurements of solar radiation have been made in various parts of the world with a number of mutually incompatible instruments, including some of very little scientific value, e.g., the black-bell thermometer. The International Meteorological Conference held at Innsbruck, 1905, recommended the use of the Ångström pyrheliometer, and this instrument has since been employed at most large meteorological observatories, as well as in the course of special investigations, as for instance on various mountains (Monte Rosa, Sonnblick, etc.). Thus the Ångström instrument has been the basis of a large body of data on the intensity of solar radiation in different parts of the world obtained by identical and approximately accurate methods, a class of information the need of which has been sorely felt in the study of the "Unfamiliar" Unfamiliar, however, other opinions seem to be divided as to whether the Ångström pyrheliometer should be retained as the standard. The silver-disk pyrheliometer of Åbbot is coming into wide use. Thus the initial problem is the selection of a satisfactory instrument—appears to be still unsolved.

## Aeronautics

**The Aesculapion Lamp and the Radiator Cooling.**—In patent No. 1,049,330 Don W. Hackett of Cleveland, Ohio presents an automobile radiator around which is expanded at its opposite side in its upper portion beyond the normal outline of the radiator and sleeves are provided within the expanded portion to receive the lamps so that the lamps are exposed to the radiator or engine which has a greater width than depth and a longitudinal open space in which a car is hung the gas bag forming an aeroplane.

**Another Flying-machine Patent.**—In patent No. 1,049,415 Bill Pollak of Washington, D. C., assignor of one half to Edward K. Clement of Washington D. C., shows a flying machine comprising two longitudinal cylindrical bodies which are connected at their ends to form an elongated integral rigid rod or envelope which has a greater width than depth and a longitudinal open space in which a car is hung the gas bag forming an aeroplane.

**Flights in Greece.**—Favored by fine weather, Laurore made a number of over-sea flights near Athens and after flying in the neighborhood of Delos in the afternoon came above the Acropolis and the Parthenon at a great height. His performances at the Piræus port were witnessed by great crowds of spectators and also by the ministers of war and the navy. In all these flights he carried two passengers on board, these being the brothers (Laurand and Berni). The latter is proceeding to join the Epurus army with an aeroplane which he has in patent. The Greek lieutenant Nektaras and Kamberos are embarking with their Parmarion aeroplane to join the same army. Lieutenant Kamberos came lately made some flights above the islands of the Aegean Sea upon a Parmarion hydro-aeroplane.

**An Incendiary Bullet.**—Twice have been made in Germany with a special projectile which is intended to repel dirigibles and which is designed not only to pierce a gas envelope but also to set fire to the dirigible. This projectile fired from the old German rifle known as "model 71," which has a caliber of 11 millimeters, is provided with little wings that open in flight under the influence of a spring, somewhat like those being the projectile still in the rifle barrel but expanded as soon as the muzzle is passed. An ordinary bullet leaves such a small hole in an envelope that the gas escapes through it but slowly. The wings on the improved bullet tear a hole of appreciable size in the fabric. When the wings are fully open, they are sufficiently to cause a fast motion to ignite fulminate contained in the bullet. It is said that experiments conducted at Neumagnum gave encouraging results.

**Another Proposed Transatlantic Flight.**—The aviator Beckmann of Cologne, is preparing to make a seasonal flight across the Atlantic from New York to America. He intends to start from the Cape Hatteras in west Spain and fly across to Fiversham the first of the Azores Islands, or 1,000 miles. From there he is to attempt the flight across the ocean to Halifax, which will mean about 1,800 miles. He will take on board 2,000 pounds of gasoline and oil, and is to fly for about 11 hours at 90 miles an hour for the Azores trip. Then he will take on 4,000 pounds of gasoline and the flight to Halifax will last 22 hours at a more than slower speed. This German transatlantic machine is to be a monoplane of no less than 45 feet in length and 56 feet spread, having a supporting surface of 340 square feet. The weight of the aeroplane is 1,500 pounds, and the framing is of steel tubes. It is to have two volving-eyer motors each driving one propeller. Windward and tailwinds and updrafts will be carried on board. This may be another case where wireless will prove useful at sea.

**News of Bue.**—The Bue grounds near Verailles are likely to become the leading aviation airport in France. Among the constructors, Konrad-Dietrich, M. Farman, H. Farman and Bore have already made their headquarters on the grounds, and at present Biffert is establishing a model aerodrome of considerable size. The work is, in fact, nearly finished, and the new quarters, built entirely of wood, will be ready for occupation as an immense hangar, with two wings of two stories each. The great hall of 170 feet in length is able to house quite a number of aeroplanes, and counting the repair shops which lie at each end, the building is in reality over 450 feet long. The work here will be very busy. On the ground floor the office and a store room with extra parts for aeroplanes, besides a good-sized workshop. On the second floor are the apartments used by the pupils, workmen, guards, etc. Biffert also has dwelling quarters here as he is to be working here now. In addition, the main building are two metal hangars which already contain several aeroplanes. It is expected to have about 25 aeroplanes in use for instruction of pilots, at the start. Behind the hangars will be built a large building, and upon the roof of this roof is to be erected a monumental organ for the Biffert aerodrome which will cost \$35,000 alone. The track of the aerodrome is already traced, and it will be of unusual size. It runs around the Bue for about 1.5 miles. The Bue is owned by M. Collin, who has already trained 250 pilots in the Pau and Etampes Biffert schools, is to have charge of the aerodrome.

### The Voice-operated Typewriter

**ANALYZER** the physical operation of taking down dictation on the typewriter. The dictator pronounces a word, say "net" and within a fraction of a second the letters "n-e-t" are struck upon the machine.

Fig. 1—Arrangement of reeds. Fig. 2—Electrical connections of the reed system.

In that brief interval of time the following operation takes place:

The ear drum of the typist, being vibrating as it receives the sound waves from the dictator. Superimposed upon the main sound waves are vibrations of different frequencies, one characteristic overtone for each letter of the word. These waves are communicated to a set of fibers in the coiled or internal ear. There are many thousands of these fibers, each tuned to vibrate to its own individual frequency.

These of these fibers are then vibrated more strongly than the rest one after the other to correspond with the "n-e-t" sounds, and the excitation of these fibers is communicated to the brain which in turn controls the muscles of the typist's fingers, causing them to strike the corresponding keys on the typewriter. No complicated mental processes need be involved in the operation. It is quite mechanical. Indeed, the typist may have been and probably was thinking of something quite foreign to the subject. But if the system is actually, why does not some one build a mechanical substitute for the typist, so that the dictator may control the machine by voice without a human inter-medary?

Mr. John B. Flowers, a young electrical engineer of Brooklyn, has actually made the attempt and with a considerable measure of success. In his apparatus a telephone diaphragm takes the place of the human ear drum. Instead of the fibers he employs a set of steel reeds, respectively tuned to the different overtone frequencies of the alphabet. For nerves he uses electric currents and for the human hand a bank of solenoids.

A diagram of the arrangement is shown in Fig. 2. When a word is spoken into the transmitter, the field of the electro-magnet *H* is varied in accordance with the sound waves impressed on the diaphragm of the transmitter. There are four electro-magnets *H*, and each is fitted with eight reeds but for purposes of discrimination and for the sake of simplicity we have shown only one of the magnets and a single reed *C*. Although the reeds are tuned to differ out many frequencies, they are all vibrated more or less by the variations in the field of the electro-magnet. But as each letter sound is uttered the reed that is tuned to that particular letter vibrates more strongly than the rest and closes the circuit of the corresponding reed magnet *D*. This closes the switch *E* actuating the solenoid *F* to pull down the key of the typewriter.

The electro-magnets *H* are virtually telephone receivers and the reeds *C* are their diaphragms. Fig. 1 shows how the reeds are mounted at each end of the magnet *D*. It is as if the diaphragm of the receiver had sectors cut out of it leaving a cruciform diaphragm mounted on standards at the four ex-

trimities and separated into four reeds by cutting it apart at the center. It is evident that these reeds would vibrate more or less according to the sound, just as a telephone receiver diaphragm would.

With this crude apparatus, which is shown in the accompanying photograph, the inventor has succeeded in recording on the typewriter all the vowels and the consonant "v". The consonant sounds are much more difficult to reproduce

A machine that typewrites what is spoken to it

for the reason that they are of shorter duration, and any mechanical device such as a reed would be too sluggish to respond to them. However, the inventor expects to overcome this defect by using electrical resonators in place of reeds. The arrangement is shown in Fig. 3. In this case the transmitter circuit connects inductively with the resonator magnet *H* and *I* across which are connected resonant local circuits each comprising a balanced inductance *K* and capacity *J*. On speaking the word "net" into the transmitter, the three local resonant circuits corresponding to the letters "n-e-t" are successively thrown into resonance. The current riding to a high value. A small vane of some magnetic material is caused to be pulled into the center of the coil *K* of those circuits which are highly excited, thus closing the circuits of the solenoids *F*, working the keys of the typewriter. The electric resonator system has not as yet been put to a practical test, but theoretically it should be very sensitive and quite capable of catching the overtone characteristics of the consonants.

Apparently, then, all that the dictator need do is to speak into the ear of the mechanical typist and his

(Continued on page 154.)

Gatun locks range tower as built.

### Architecture on the Panama Canal—A Suggestion

**NO** one who is familiar with our columns would guess, I think the friendly spirit in which the criticisms suggested by the two adjoining sketches at the bottom of this page is made. The character of the permanent masonry work along the Panama Canal is such that it does not admit of much architectural adornment or expression, and in view of the magnitude of the huge monolithic masses which constitute the locks, spillways, etc., we think it will be agreed that the simplicity which characterizes these works is appropriate. At the same time, in the designing of the subordinate or accessory structures, such as power houses, range towers or lighthouses for marking the course of the vessels, and the permanent buildings for housing the operating and military forces, we think that great care should be taken to make them architecturally harmonious with the spirit and purpose of this, the greatest engineering work of the day.

The range towers, of which there is a large number placed at intervals along the milling route of the canal, are concrete structures of circular cross-section and of simple and appropriate design. In the case of one of these towers,

Fig. 3—Connections of the electric resonator system.

known as front tower of range No. 1-3 in the Gatun Lake section, it became necessary to make a radical change of form, owing to the peculiar requirements of the site and the result is shown in the accompanying half-tone engraving which is reproduced from the last annual report of the Panama Canal Commission. The tower is situated on the south middle wall of the Gatun locks, which extends from the main structure several hundred feet out into the lake. Upon this wall are located three tracks for electric towing locomotives.

one on each edge of the wall, used when the ships are in tow, and a third track to enable the locomotive to return after they have carried a ship through. In designing this range tower, it became necessary to depart from the standard circular form, since the structure had to span the central track with sufficient clear space to allow of the passing of the locomotive.

Unfortunately, the problem was treated as one merely of engineering. Four concrete pillars 30 inches by 24 inches in section were carried up the desired height, arches were thrown in, and a platform was formed above them. From the center of this massive slight rectangular base rose the massive circular shaft of the lighthouse.

Now, appearing from the accompanying manuscript, this is a perfectly satisfactory structure, as most engineers

The tower as it might have been built.

### The Moreau Automatically Balanced Monoplane

**M.** MOREAU of Paris has been testing a monoplane which commands attention chiefly because it is provided with an automatic stabilizer. He claims that he has flown thirty-five minutes without touching a lever, steering with his feet. By what the writer saw in a short flight, he believes that the feat is possible in good weather.

It has provision both for automatic stability and for personal control. The lateral automatic stability is secured partly by the wing shape, partly by the low placement of the main center. These are old and obvious devices which serve in favorable measure and in easy maneuvers. Longitudinal automatic stability is secured by placing the pilot in a pendulum seat shielded from the wind, movable only in a fore-and-aft direction, and actuating control cords running back to the horizontal rudder. This general pendulum device for automatic control has formed the basis of many patents, but as here applied has some noteworthy features presently to be indicated.

As to the mechanism for personal control, the steering is done by the feet working cords connected with a rear vertical rudder, the lateral pole is effected by ailerons operable by a special lever, the longitudinal pole is obtained by another special lever operating the horizontal rudder. All these personal control devices are old and well known.

The most interesting feature of the Moreau monoplane is the combination of arrangements for longitudinal control. As already stated, the rear horizontal rudder is operable automatically by the pilot's seat which undergoes all longitudes of the machine, and manually by a special hand lever. But, furthermore, there is a brake operable either by the hand actuating a lever or by the wind setting on a pressure plate, whose function is to lock the pendulum seat so that the whole machine becomes, for the time of braking, as one rigid body. Thus the aeroplane is instantly convertible from one having either manual or automatic control to one having only manual control, and in either case it has considerable inherent stability by virtue of its shape and low center of mass.

The pilot-seat pendulum of Moreau's monoplane which has also characterized the designs of other inventors, has the advantage of exerting sufficient force to work the control wires unaided by auxiliary power, whereas the light pendulum control so frequently proposed, during the past generation or more, for automatic stabilizing, require some intermediate mechanism and a special source of power, such as compressed air, or gearing driven by the motor, etc. But it may be observed also that the period of vibration of the larger pendulum is longer than need be for a small one, and hence in some circumstances its action may not be quite so prompt. The ideal aeroplane pendulum should always maintain a fixed direction, or, if disturbed, would promptly and without oscillation resume its normal direction, say the vertical. Like the magnetic needle, it would be unaffected by sudden shifting or acceleration of its pivot. The aeroplane could then be given a definite pole with respect to the normal position of its pendulum, with the assurance that the pole would in general be uniform. But the ordinary pendulum, when its pivot is accelerated transversely to the line of suspension, promptly deviates from the natural plumb, to which it tends to return for repose gradually after one or more vibrations. The most frequent and prolonged steady oscillations, the more untidy the control of the machine on its course.

If, for example, the aeroplane is accelerated on its path, as when starting along the earth, or when the propeller thrust suddenly increases, the pendulum tends to lag behind, thereby changing the angle of the rudder more, perhaps, than the circum-stances require, or if any change at all be desirable at the least. Conversely in landing, when the propeller thrust suddenly diminishes, the pendulum swings about of its natural plumb position with a consequent disturbing effect on the evenness of the straight forward flight. But if a brake is available, which automatically locks the pendulum during certain extraordinary accelerations of the aeroplane, due to sudden changes of propeller thrust or sudden wind gusts, these violent movements of the pendulum and their consequent disturbing effects are obviated.

Apparently such a pendulum control should be resorted to as a filler between the two, and perhaps it can, where the

Near view of the pendulum seat

pilot during much of the time even if it cannot be depended upon to save him in the most severe atmospheric conditions. It may be expected, therefore, that it will better be forthcoming, the pendulum control will favor with some aviators, as a convenient auxiliary if not as a life preserver. But it must be remarked that

Drzewicki's machine rearing, on even keel, and diving, a difference of 8 degrees between each position

The Drzewicki tandem monoplane constructed according to results of Eiffel's aerodynamic research.

although practical automatic controls of various pendulum types, as well as other kinds, have been shown by their inventors to be mechanically operative, they have not made remarkable headway toward general adoption, either by operators or by manufacturers of aeroplanes. These remarks apply to pendulums of ordinary type, whether working the controls directly by their own weight or through intermediary gear involving electric chains, compressed air cylinders, or the power of the aeroplane motor.

In closing references may be made to an automatic stabilizer governed by an extraordinary pendulum. Mr. John Tarbox of Washington has piloted a biplane with him at its center of gravity so as to obliterate disturbances due to sudden shifting or acceleration of its axis. In order to endow it with a tendency to stand plumb, one end is made bulbous and the whole is immersed in a liquid contained in a box mounted on the aeroplane. The pendulum is used to operate a clutch, whereby the power of the motor may be engaged to work the control wires of the aeroplane. The Tarbox stabilizer when mounted on a biplane of the Curtiss type enabled it to maintain a level pole in cross-country flying and to fly continuously round a curved course, steadily maintaining a given bank in calm air, and promptly returning to its prescribed pole when navigating disturbed air. As witnessed by the inventor in 1911 it was used to control only the ailerons, but it can as well be applied to control the horizontal rudder. The inventor claims for this stabilizer all the merits of those operated by common pendulums plus the additional advantage that the pendulum is unaffected in vertically by any acceleration of the aeroplane due to sudden change in the propeller thrust etc. as observed for the Moreau machine. The correctness of the principle of the Tarbox pendulum may be left to the intuition of the reader or as an exercise for his skill in hydro-mechanics. The question is whether a pendulum pivoted at its control and more buoyant in its upper than in its lower part will preserve its verticality while its axis is being transversely accelerated?

### The Drzewicki Following Surface Aeroplane With Inherent Longitudinal Stability

**T**HIS machine is distinctly of the Lanchester type and it is the outcome of the various forward machines of the Lanchester type originated by the Volzud several years ago, and first tried by Santos Dumont in his original aeroplanes—the first heavier than air machine to fly in France. The Lanchester type consists of a long body carrying the elevator and vertical rudder at the front end and the supporting surfaces at the rear end. The elevator is placed just in front of the planes in the body and the motor was placed at the rear part of the lower plane as in the usual biplane. The Drzewicki machine, however, has both surfaces of the same size and both lift about the same amount. Both the motor and the motor are placed in the body between the two supporting surfaces, while the propeller is located at the rear end of the body behind the second plane. The center of gravity is practically at the center of the fuselage half way between the two surfaces. This is important as the position of the center of gravity influences the direction of the correcting couple when the machine tends to lose its balance, and also affects the magnitude of this couple. The machine is balanced in such a way that in ordinary flight the front surface has an angle of 8 degrees, and the rear an angle of 8 degrees. There is therefore a dihedral angle of 16 degrees between the two surfaces in a longitudinal direction. The front plane has the profile curve of the No. 13 Eiffel surface which, given at 5 degrees a lift of  $K_p = 0.0141$  approximately. Moreover, because of the difference in the two planes, the total lift of the front one varies less quickly than that of the rear when the angle of incidence changes. If, therefore, the machine is out of equilibrium or in other words if the two lifts of the front and rear planes no longer balance each other with respect to the center of gravity, and the machine tends to rear the lift of the second surface increases more quickly than that of the front one and a couple is developed that tends to raise the rear of the machine and correct the increase in the angle of incidence of the two surfaces (see diagram). In the case of a dive when the angles of incidence of the two surfaces

diminish, the difference in lift of the two planes occurs in an opposite manner, and the greater lift of the front one brings the machine up to an even keel once more.

This principle was tested out in the Eiffel laboratory on a model one-tenth the size of a full-sized machine. The model was suspended at different angles of inclination and the experiments proved that it is possible to obtain longitudinal automatic stability by the arrangement of the plane surfaces whereby the lift of the rear plane is set at an angle of 5 degrees less than the front one. Moreover, it has been proved by experiment that when the planes both have the same angle, the lift of the second one is practically nothing. If the second plane is given a decrease less angle than the front one there is no lift at all but rather a downward force. If the second plane has less angle at 25 degrees than the front one however, the lift produced is practically the same as that of the front one so that in addition to obtaining automatic stability a lift as great or greater than that obtained with an ordinary biplane is to be had. These results were obtained experimentally by Eiffel and M. Drenowicki constructed his machine in accordance with them.

The forward wings can be turned about their axes in order to correct the lateral balance and also to increase or decrease their angle of incidence when it is desired to rise or descend. Each wing is built about a central spar that turns in a ball bearing and can be operated by hand or together by means of two levers. The two vertical rudders on the ends of the rear wings can be turned inward across the machine at right angles with its axis, in order to form a brake, when the machine makes a sudden descent. The motor used is a 70 horse-power "Naiman" although the machine is provided with oleo-pneumatic shock absorbers so arranged that the moment the wheels strike the ground a shock is thrown downward in contact with the soil acting as a brake.

In the pages of the current *Scientific American Supplement* will be found a discussion of the design from the aerodynamic standpoint.

### New Types for the Japanese Navy

By Oscar Parkes

THE sister ships, "Kawachi," which was commissioned last year, and "Retou," due for completion this year, are Japan's first all big gun ships to be built. These predecessors, the "Aki" and "Mikuma," although often classed as dreadnoughts, were intermediate-like the French *Lunon* and the British *Lord Nelson* types, as they carried a main armament of four 12-inch and twelve 10-inch guns. The Kawachi is the normal development of the Mikuma, and the design seems an enlarged "batter" with 12-inch guns replacing the 10-inch ones at the four corners of the superstructure, her twelve big guns being distributed after the earlier German fashion, now discarded in that and other navies in favor of the center line arrangement. The Kawachi displaces some 20,700 tons, her dimensions being length over all 461 feet, beam, 40 feet, and maximum draught 29½ feet. An originally designed she was to have carried fourteen 12-inch guns, with triple turrets fore and aft and four twin position ambships, but this was modified in the earlier stages of construction to twelve guns, twin turrets replacing the triple.

Her secondary battery of ten 6-inch pieces is distributed along the main deck, and the guns being recessed to secure axial fire. The 47 guns are mounted at the extreme bow and stern and in the superstructure. Five submerged torpedo tubes are carried (two bearing on each broadside, and one astern). These fire the 18-inch "fish" and water torpedoes.

Her protection consists of the usual complete Japanese belt 12-inch amidships, tapering to 5-inch at the bow and stern which reaches to the lower deck. Above this is a 6-inch armor belt amidships, reaching to the battery deck, and here the guns are belted 6-inch at center. A 3-inch armor deck encloses the engine and vitals. All the big gun turrets are 9 inches thick and are reported to have 12-inch belts.

Both ships are turbo-driven, the "Kawachi" having Curtis engines and the "Retou" Parsons. Steam is generated in 16 high-pressure boilers of standard Japanese pattern and the designed horse-power of 25,000 is expected to produce a speed of over 30 knots. The coal supply is for four months and the range is 10,000 miles.

From our illustrations it will be seen that the ships present a somewhat unique appearance owing to the peculiar funnel spacing and the two tripod masts of British pattern. The "Kawachi" was laid down at Yokohama in January, 1917, and the "Retou" in April of the same year, but owing to financial reasons the latter will not be completed until some time in 1918.

The battleship *Kongo* is one of a class of four ships of 27,000 tons displacement, and is under construction at the Yokohama yard. Her dimensions are length, 504 feet, beam, 92 feet, and draught, 27½ feet, and she carries an armament of eight 16-inch and sixteen 6-inch guns.

The big guns weigh 50 tons and are 45 calibers long. They are mounted four forward and four aft, the second and third turrets being raised "Michigan" fashion to allow an axial fire of four, and a broadside of eight guns. Along the upper deck are the 6-inch guns, and on the turret tops and upper works are distributed sixteen smaller quick fire pieces.

Official details of the armor and protection are lacking, but reliable information from the belt is 10-inch amidships, tapering fore and aft and terminating some distance short of the extremities.

Beneath this is an auxiliary belt which is very deep, protecting the ship against under-water attack. Above is a 7-inch armor deck, and a broadside of eight turret bases, and the battery is belted 6-inch armor. The protective deck is 2 inches thick.

Her 16-inch guns are in 0° inch turrets with armored bases of unknown but probably similar, thick case. Driven by Parsons turbines of 60,000 nominal horse-power the *Kongo* has a designed speed of 25 knots, but 27 knots is expected of her. She carries 4,000 tons of coal and 1,000 tons of oil fuel.

Of the four ships, the *Kongo* was laid down in January, 1911, and is to be completed early in 1918. The "Haruna," (Curtis turbines), "Kishirishima," and "Ibuki" are all building in Japan, and are due for completion between 1914 and 1916.

### Ducommun's "Cold Light"

RECENTLY the experiments that M. Ducommun, a French savant, has been carrying on since 1900 at his "Cold Light Laboratory," have occasionally filtered into the newspaper columns as news reports, although as a time examined and perverted, have created considerable curiosity about Ducommun and his work. While the discoverer has made much not "revolutionary" electric lighting," as one recent press story predicted, (truth be told, the French savant has applied some old principles to new) and ingeniously devised lighting apparatus, and has conceived some really starting applications for the latter. On three occasions communication to Ducommun have been presented to that august body, the French Academy of Sciences, by Prof. Brachy of the electric telegraph fame.

Ducommun's apparatus, in its most typical form, consists essentially of the following parts:

1. A disk or wheel, with suitable mechanism for revolving it.

2. A number of tungsten filament lamps (usually 16 of them) spaced uniformly around the rim of the wheel. The lamps have small, closely coiled filaments, the whole filament structure in a single lamp occupying but a few square inches of space. The filament of an ordinary tungsten lamp encompasses a space some 2,000 times as great. The bulbs are small and round similar to those commonly used in automobile head-lights. A battery or low voltage dynamo or transformer supplies the current to the lamps.

3. A commutator, keyed to the shaft of the wheel which causes each lamp successively to be lighted, for about 1/20 of a second only, as it passes a certain fixed point near the periphery of the wheel.

4. A projecting lens so designed and placed as to receive the light rays from the lamps, as each in turn passes by the fixed point where it is lighted.

For most purposes (moving picture machine work for example) the wheel is revolved at a speed of 16 or 20 revolutions per second, so as to give the eye the illusion of persistence of vision, in that of a single steady continuous light emanating from a point. For other purposes, as for example, in light house beacons, the wheel is revolved more slowly, so that the light is seen to flash in a series of flashes.

M. Ducommun said it possible, by making the apparatus of little turtle and using special mechanism, to stop the wheel during the twentieth of a second or so that each lamp is lighted, so that the filament, while lighted, remains stationary at the exact focus of the lens. In the case of lamps with fairly large bulbs, when necessary he mounts the filament off center, thus bringing it very close to the focusing glass of the bulb for the little incandescent coil to be in focus.

There is much to be obtained from this, but now comes the spectacular part of the performance. Using the apparatus above described, Ducommun finds that more than twice their normal voltage can be impressed on the lamps, yet they will not glow for several hours, while the light is obtained at an economy of electrical energy absolutely unknown with any other illuminating device using incandescent lamps. Thus, by doubling the impressed voltage, a lamp normally giving out 0.1 watt per candle-bulb will give out light at an efficiency of 0.3 W. P. C. It actually impresses 2½ times the normal voltage in certain applications of the apparatus, such as medical examinations of interior parts of the body, and thereby raises the light intensity to 2½ times as much as that of the yellow flame arc.

While the efficiency is increased by "overvolting," the candle-power obtained from a given bulb is in-

creased in still greater proportion. Thus a 300 per cent of normal voltage, a ten candle-power lamp, with a bulb less than two inches in diameter, emits a light of over 140 candles.

There are two advantages in Ducommun's scheme of using several lamps in rapid rotation, rather than a single lamp continuously. In the first place, the life of each filament is increased about twenty fold, since it is in continuous motion the length of the time. Secondly, the bulbs do not have a chance to get hot, a fact of great importance when they are used close up to moving-picture films or expensive lenses. Thus the light is a "cold light" in a double sense, very little heat is evolved, and the lamps are so long lived, and even that little is so thoroughly dissipated that the apparatus remains cool.

The light intensity in a given direction may, of course, be increased by the use of a reflector in addition to the concentrating lens. Ducommun has two forms of apparatus employing reflectors, in one form the reflectors are rigidly attached to the lamps on the wheel, and revolve with it, in the other form there is a single fixed reflector mounted coaxially with the concentrating lens.

The distinguishing principle of Ducommun's "cold light" may best be stated in his own words:

"This method dissipates the objectionable heating effect of the electric current under a maximum surface where it comes in contact with the object, and has no useful luminous effect on the minimum surface where it is needed."

With a consumption of only 180 watts of electrical energy—which will not produce even the smallest amount of heat, the apparatus under review has no disadvantages in projection work that would be impracticable with even the largest arc manufacturers.

The applications that Ducommun has discovered for his invention have done more to bring it into public notice than has the mere fact that the light is so amazingly efficient and intense. And the man is no dreamer. Already he has induced the French Minister of Instruction to give the "cold light" a thorough try-out in the public schools in connection with educational moving picture shows, and the inventor has been considering its applicability to military search lights.

Owing to the comparatively high expense of bulb renewals with the Ducommun system, as well as the necessity of moving parts, one is inclined to view with incredulity the inventor's claim that his system is so much more favorable than a general illuminant, although the inventor rather naively suggests that it may be used with his low inverted reflectors to produce beautiful indirect lighting effects in drawing rooms, conservatories, etc. In private conversations with the inventor, however, applications of electric lighting, to the development of which he is wisely concentrating his attention.

Among these special applications is that of endoscopy or examinations of the internal organs of the body. No intense is the light that, when it is placed under the hand the finger bones and principal blood vessels are clearly seen. In many cases it is believed that this powerful, cold light will enable bullets and other foreign substances to be located without the necessity of an X-ray examination. Letters can be read, it is said, even when wrapped in a dense thickness of note paper and inclosed in an envelope.

A second application, already mentioned, is that of cinematography. Ducommun claims that his apparatus will do away with the cumbersome machinery of the cinema and substitute-lined cabinets now in use. No shutter will be necessary to cover the lens during the interval of 1/24 of a second between two successive pictures, for that can be taken care of by a mechanical device, which causes the "cold light" to be extinguished during that interval. Moreover, the present commercial dimensions of the positive, 8½ x 10 centimeters, can be reduced to 10 x 24 millimeters, owing to the possibility of using incandescent "short focus," 50° cone angle, "pencil" mode, incandescent lamps, as an illuminant possibility. The cost of the lamp bulbs with the Ducommun machine is about equal to the cost of current with an arc, but a considerable saving is said to result on account of the shorter life of the "cold light" lamp.

Paradoxically, the Ducommun "cold light" is produced at an unusually high filament temperature; indeed it is that very fact that makes the "cold light" possible. A high-temperature radiator is rich in the shorter wave lengths, and the "cold light" is a result of this. As chemists the word "cold" is not a contradiction, it follows that the new light is a good one for photographic purposes, such as the making of silver prints. For flash-light photography it can be used on many occasions when magnesium flash is not available, and the light is as bright as that of the "cold light."

M. Ducommun is experimenting with a "cold light" machine in which the lamp and optical system are of quartz instead of glass, in order that the chemical and pathological effects of the ultra-violet rays may be studied.

Recent reports indicate that Ducommun's "concentrated cold light" has another field of practical usefulness in light-house beacons.

# Shall We Build Battle Cruisers?

Every Big-gun Cruiser Would Mean One Less Battleship in the Fighting Line

By R. D. Gatewood, Naval Constructor United States Navy

1. There can be no doubt that there are many adherents of the new and very interesting type of ships that has recently come into being, variously termed "battle-cruisers," "cruiser-battleships," and "high-speed-battleships," and that there is considerable criticism of our Navy Department, both in this country and abroad, for not building them. It would be difficult to say whether this is due to the fact that other powers have them and we have not, or that the type with its greater size and speed, and its powerful guns, appeals to the popular mind, or that we really do need them.

2. Involving as it would a change of policy and a very large expenditure of money, let us consider the matter from every viewpoint before answering the question that forms the title of this article.

3. These vessels first came into being in 1900 with the British "Indomitable" class. To-day both England and Germany have battle-cruisers in considerable numbers, and are building more. Japan is building four. We, however, have none nor are any yet projected.

4. Battle-cruisers differ from our temporary battleships in three main features:

- (1) Greatly superior speed
- (2) Slightly inferior battery
- (3) Greatly less protection.

An examination of Tables I and II taken from Jane will make this quite clear. It will be noticed that while the standard battleship speed stands at about twenty-one (21) knots, the battle-cruiser speeds are from thirty (30) to forty (40) per cent higher. The size of guns in both types is the same but the cruisers carry fewer of them. The armor belt, which is also thinner on the latest British and German ships, is not only much less in thickness, but is spread over a less area and is tapered more at the ends than is the case with battleships.

5. Future battle-cruisers will almost certainly maintain these differences, and any that we design will in all probability be built to have a radius of action greater than those of other countries, since our strategic position is such as to require this. If we adopt this type, we may therefore expect to have even bigger and more costly ships than any other nation. Assuming that we decide to build such vessels with a speed of thirty (30) knots, an armor belt of eleven (11) inch thickness, eight (8) 14-inch guns, and a radius of action of eight thousand (8,000) miles, a fair estimate of the cost of a single vessel would be twenty million dollars (\$20,000,000), and this, of course does not include the large incidental expenditure involved in deepening channels and enlarging docks which would be necessary.

6. To be of any real use, either tactically or strategically, at least four of such ships, or one division should be authorized, and not a single unit. Just here it is interesting to reflect that any vessel appropriated for in 1919 could not join the fleet before 1918. At that time, assuming that we build two capital ships per year from now on, the situation will be

	Japan	Great Britain	United States
Battleships	6	17	11
Battle-cruisers	7	8	0
Battle-cruisers, Second class	13	12	24

Thus, even if two battle-cruisers should be added to our fleet by 1919, they would be opposed to eight similar cruisers of Germany, or seven of Japan, and it is difficult to see how so small a number could accomplish anything.

## Uses.

7. In considering now the uses to which this type may be put we naturally consider them under three heads: (1) Before action, (2) In action, (3) After action.

(a) Before Action.—There is no question that they

would be very valuable for quickly reaching a sea out, or occupying an advanced position of importance or relieving a threatened force, or reinforcing another fleet to a given time all of them could require high speed as well as offensive power.

They would be useful as scouts but here several things are likely to be overlooked. In the first place, the maximum speed of one of these cruisers cannot long be maintained on account of the excessive coal consumption. At full speed, they will probably burn the equivalent of one thousand (1,000) tons of coal per day. Also it is very questionable whether any commander-in-chief would care to detach far from his battleships vessels that could deliver such powerful blows in the fighting line. Then, too, for anything but distant scouting the cruisers are undoubtedly going to be superior to any ship. The strong claim made for

naval battles at Aboukir, Trafalgar, Lissa, Yalu, Manila, Santiago, and Tsushima, there has always been a very decided attempt to force the issue of the action in the shortest possible time by making the attack of all possible units, and I believe that in the last analysis, any such cruisers as we might construct would, of necessity, operate in the line of battleships.

## Conclusions.

8. England is building this type because she already has an extremely powerful navy in conjunction with which this can be used to the best advantage and also because she needs them to protect her rich and widely separated colonies. Germany is building them because England is, and because she seems able to afford both battle-cruisers and battleships at the same time. Just why Japan is building them at the expense of battleships is indeed difficult to see, but that country has four powerful battle-cruisers of the Kongo type, as illustrated on the front page of this issue.

9. For the United States it must be clearly understood that such cruisers could only be constructed at the expense of battleships. We cannot have both and from the above it is seen that we cannot have the latter without incurring a very great expenditure direct and incidental. Under no circumstances should we jeopardize our chance of keeping our battleships first class to an adequate standard, and until we can maintain that, the battle-cruiser is a luxury that we can ill afford.

## The Technical Expertise Station of Vienna

WE have received the following communication from the Technical Station of Vienna:

"This station plans to prepare a director of all technical expertises stations at home and abroad.

For our records we require the following data:

Statement of the special field covered by the experiment station addressed, name of owner, director and employees, date of erection, furthermore statement as to whether the institution is independent, or is connected with an institution for technical instruction, or with a factory company or other industrial institution, whether the last type is open to the general public, or has been installed only for private practice trials, details regarding the installation and size of the institution.

All technical testing stations, excepting those, who have already communicated with the undersigned, are, therefore, requested kindly to make early response to this inquiry.

The Imperial Testing Office is also prepared to receive information regarding new developments and departures in the field of technical testing.

This Imperial and Royal Testing Office,  
January, 1919. KRAUS, President."

## Using Ice to Save Apple Trees

A MARYLAND orchardist has found that the way to spring like winter prevent this winter in some sections of Maryland promises to cause a premature blossoming and budding of apple trees, and is said to have purchased a hundred tons of ice and cracked or broken the same into small pieces which he has packed about the roots of the trees to produce in this manner a temperature which will retard the blossoming of the trees. It is a common expedient to heat orchards to prevent injury by frost, but this is believed to be the first instance where artificial cooling has been resorted to. The orchardist declares that if in the warm weather comes, the apple and peach crop in this section will be considerably reduced, and that if severely destroyed unless some means are resorted to prevent the premature blossoming.

In this connection it is interesting to note that the official news recently given to three cruisers in Germany is *Linschmidt Kreuzer*, or cruisers of the line.

battle-cruisers for this short range scouting is that, when used in a screen, they can drive in the scouts of the enemy and prevent them from getting valuable information, and they may even be able to force an action where the enemy is unwilling to engage.

(3) In Action.—When the action is actually joined they would be very useful in obtaining a position at the head of the enemy's column, opposing his weak end or fire with their powerful broadside fire and thus "cupping" his column, as it is called, and forcing him to change his course. Or they might be used in the way talked of, but never used, formation of the "fast wing," which is simply a detached body available for threatening the head or rear of the enemy's column or a weak point in his line.

(4) After Action.—Assuming that these cruisers have preserved their speed after the battle which on account of their light armor could probably only be done by keeping them out of it, they could be no doubt that they would be of great value in the pursuit of a damaged and retreating enemy either in heading him off from his flank, or in reinforcing pursuing destroyers.

8. The above is an outline of the probable uses that would be made of this type by the powers possessing them. Should we attempt any of them, however it will be at once seen that against any probable enemy we will be hopelessly outnumbered. Also, in all the great

### Photographing from a Skyrocket

It takes an active imagination, surely, to see any sympathetic relationship between a skyrocket and a camera—so delicate is the one, so heterogeneous the other, but the fact was not beyond the powers of Mr. Alfred Maul, who has linked the one to the other in a happy co-terminity: the results of which are shown in the accompanying excellent photograph taken by his device.

The rocket-camera as it might be called, was designed for military purposes and was demonstrated before the German military authorities with such success that it has been officially accepted. The problem was not at all easy, and the inventor claims to have been trying, to take up these two very dissimilar things for some twelve years, for it has taken that time to bring the device to its present undoubted perfection.

The accompanying illustrations, for which we are indebted to the *Illustrated London News*, show the construction of the camera-carrying rocket, the method of mounting and firing it, and the way in which it is knocked down and picked up in a light handcart for transportation. The apparatus is described as consisting of a camera held in a padded box, at the top of which is a pneumatic electric contact, and a holder which contains a parachute and the upper part of the rocket. On the top of the holder is a gyroscope which serves

definition, that they could not fail to give valuable information regarding the strength and disposition of the enemy's troops, artillery and earth works.

### The Enlargement of the Aswan Dam

By the English Correspondent of the *Scientific American*  
THAT great engineering work, second only in magnitude to the original construction, the enlargement of the Aswan barrage across the Nile, has been completed. The work has been in progress for nearly six years, and although of a somewhat delicate character, it has been carried through to completion without a single untoward incident.

When this barrage was first contemplated Sir William Willcocks, the eminent irrigating engineer, recommended that the great wall across the river, 121 miles in length, should be of sufficient height to impound the water to a level of 114 meters (380) feet above sea level, the maximum head of water then obtained being 26 meters (86 feet), whereby the volume of water stored would amount to 88,800,000,000 cubic feet in round numbers. This seems an enormous volume, but it was only a little more than fifty per cent of that actually required to meet the needs of the country which would be secured.

Unfortunately, public opinion demanded the reduc-

tion of the dam. Sir Benjamin Baker recommended that, in building up the new joint of the masonry, a space ranging from 3 to 6 inches should be left until sufficient time had passed to enable the temperatures of the old and new masses to become equal, when they were to be connected by cement grouting.

Accordingly, the new work was built up in front of the old, and was not connected to the latter except by a number of steel rods of 1½ inch diameter and 8 feet in length, sunk to a depth of 4 feet into the old work, and disposed at intervals of about 8 feet 6 inches. Extreme care had to be exercised to keep out mudstone, and also to prevent debris from filling and collecting in the space between the two sections.

The work of attaching the new masonry to the sloping face of the dam had to be carried out during the periods when the sluices were shut, temporary embankments being improvised with bags of sand to keep the working area dry. The work was done in separate sections, and as it was spread over five seasons, adequate time was offered before the new and old parts of the work were connected by the grouting. Owing to the careful arrangements made by the contractors in regard to labor, the programme, carefully prepared before the work was started, was carried out exactly as planned, and the new parts of the wall stood fully

### ROCKET PHOTOGRAPHY

to maintain the camera in the desired position for the snapshot. The stick of the rocket is about fifteen feet in length, and it is fitted at its lower end with wooden feathers. The whole rocket is twenty feet in length and it weighs about eighty-four pounds. The camera is capable of taking eight by ten inch plates.

After giving the proper direction in firing the rocket is mounted in a special form of "gun-carriage" which is mounted at the apex of a stout triangular base and is capable of being elevated through any range from the horizontal to ninety degrees. When the rocket is fired, electrically (from a distance of about 200 yards) the gyroscope is started, and, in about eight seconds' time the rocket with the camera reaches a height of about 2000 feet. When the rocket is turning at the highest point of its trajectory the camera being held in the proper direction, covering the field of view, by the gyroscope, the camera shutter is released and the photograph is taken. At the same moment a parachute, which forms part of the apparatus in the head of the rocket, is set free and the rocket divides into two parts. The parachute opens and the whole of the mechanism rocket head, etc. drops gently to the ground landing in about fifteen minutes. We reproduce some of the photographs which have been taken with this instrument, and they are so sharp and clear in

tion in the height of the barrage, and the Egyptian government responded to the popular outcry. However, the amended work was designed in such a manner that, if the explosives arose, the wall might be hoisted could by 6 meters (20 feet) with perfect safety.

After the barrage was opened and the widespread benefits that were bestowed by the scheme became recognized, the mistake in reducing the height of the structure was appreciated. The question as to whether a greater volume of water might not be impounded by raising the crest of the barrage was discussed. Sir Benjamin Baker stated that such an end could be achieved with complete safety, if carried out upon the lines he laid down. He prepared the plans for the alteration, which involved increasing the height of the barrage by 5 meters (16½ feet) and augmenting its thickness also by 5 meters. In this way the water level would be raised by 7 meters (23½ feet), whereby the volume of stored water would be increased from 88,800,000,000 to about 81,200,000,000 cubic feet.

The contract, which was estimated at £750,000, was handed over to the well-known British contractors, Sir John Aird & Company, who had been responsible for the original works, and to whom we are indebted for the permission to describe and illustrate the alterations. The important points were the hoisting of the

two years before the connecting bonding was taken in hand.

On the western side the barrage terminates in the structure forming the navigation lock. Formerly there were four lifts to meet requirements when the water was impounded, but in the new work a fifth lift had to be added. As far as the locks are concerned the walls of each have had to be raised, the extent of this increase varying from 1½ feet in the case of the lower lock to 10½ feet in the case of the fourth lock.

The alterations demanded extensive rearrangements in connection with the lock gates. There, as was pointed out in the *Illustrated American* upon the opening of the original dam several years ago, are of a special single-leaf sliding type. Now, as the water level has been raised, the depth of water in the uppermost locks is very great. Consequently gates 7½ feet high by 23 feet 2 inches wide, while the other gates are 20, 22½, 46 and 36 feet in height, respectively. Each is carried on a carriage which rolls over a roller path carried partly on a baulk and partly on the wall of the lock. On the land side a recess is provided in the wall in which the gate is carried when boats are passing through the lock.

In the alterations the gates were again moved bodily  
(Continued on page 143)

When the Aswan Barrage was first projected Sir William Willcocks recommended that its height should be great enough to impound the water to a height of 250 feet above the sea level. The enormous volume of 65,500,000,000 cubic feet which should have thus been stored up seemed so vastly in excess of the actual requirements that, in response to public opinion, a lower height was adopted. The reduction proved a mistake, and now it has been decided to heighten the structure. Fortunately the necessity of this heightening was foreseen so that it can be easily carried out.

The heightening of the Aswan Barrage involved the important problem of bonding new masonry with the old. The late Sir Benjamin Baker recommended that by building up the joint part of the masonry a space ranging from two to six inches should be left until sufficient time had elapsed to enable the temperature of the old and new masonry to become equal, whereupon they were to be connected by cement grouting. Sir Benjamin's plan has been followed.

## Notched Lathe Dog

By William Grötschler

**A**n ordinary lathe dog can easily be prevented from letting its work slip and causing trouble. The following method will prove good. Take a three-cornered bar and file several deep notches into its inner face at

Non-slipping lathe dog

one side. Now put the work and dog in place as illustrated, and the dog will grip it with astonishing firmness. Work as large as the dog will admit can now be turned without slipping.

## Straightening a Back Saw

**A**FTER the back saw has been set and filed quite a number of times it will become slack and kinky along the saw tooth edge. If the saw is properly con-

Straightening a back saw

structed one tap of the hammer on the back at the extreme end, will straighten it instantly.—A. B.

## Chair Making One Hundred Years Ago

By Albert F. Bishop

**Q**UITE frequently in occupying a very old chair it will away from side to side quite easily, but still the parts will not separate. This is due to the construction, which is quite ingenious. The wood is shrinking grips tightly on the rounds. The uprights or legs marked A are of green wood. The rounds and curved

Chair construction of our great-grandfathers.

Chair spindles marked B are thoroughly seasoned. You can readily see that when the green wood becomes seasoned it will shrink very tightly on the seasoned pieces, so much so that they very seldom come apart, although there is no glue used.

## Lettering Triangle

To the Editor of the WORKMANSHIP DEPARTMENT

Referring to the different suggestions for making the guide lines for lettering drawings that have appeared from time to time in your columns, I wish to call attention to a very neat device stationed at my writing desk here. It consists of a triangle made of celluloid and provided with vertical rows each of three flaring holes. Placing the point of a lead pencil into one of the holes

Drawing guide lines for lettering

of the row selected, the triangle is run about a ruler by means of the pencil point. Arrived at the end of the line thus drawn the pencil is placed into another hole of the row in question and a line drawn in the opposite direction. The operation is repeated once again and these lines will be found to be drawn exactly parallel and spaced correctly apart. The rows of holes are designated by the number of the round-writing pen best adapted for the size of letters in question.

Bonn, Germany

R. C. MANNING.

## Sharpening Edge Tools

By W. D. Graves

**T**HE essential feature of a good cutting edge is that its two sides shall form a sharply defined acute angle which can only be attained by having one side straight as shown, much magnified, at A in the drawing rather than curved as shown at B. Where the novice usually fails in whetting an edge tool is in giving it a rocking motion, producing the rounded edge, and the principal element of skill in the operation lies in holding the blade and the stone at the same relative angle throughout. There are some apparent exceptions to this rule, as the common ax, but they are only apparent, not real. An ax used for chopping is better ground with the sides smoothly curved but the sides of the extreme edge, if it is a good edge, must be straight. Of course these straight sides may be very short, only as long as they are made by the final "setting" or whetting of the edge, but they are there.

The proper "thickness" of the edge 1 e the degree of acuteness of the angle formed by the two sides depends wholly upon the nature of the tool and the work it is intended to perform. A thin edge will, of course, cut more easily, but it will also break and become dulled more quickly, so the proper angle must be determined, by observation and experiment, for each tool and purpose. The conservative beginner will aim to err in the way of making the edge too thick, then as he finds it amply strong to do the work without cutting or nicking he will make it a little thinner and so proceed till he learns the most effective and

Various forms of cutting edges.

economical angle. An edge which would be sufficiently enduring on soft pine would become almost immediately blunted on lignum vitae, while, for use on any given wood, differently tempered tools require sharpening at different angles in order to give the best results.

As most wood-cutting tools are sharpened like a chisel this form of edge may perhaps best be used in illustrating the method of sharpening ax. If the tool is very dull the work of sharpening is expedited by first grinding it on a stone or wheel of a grit too coarse to make the final cutting edge, taking care to have it symmetrical and either straight or of the curve of the grinding wheel, as shown at C. This method of making the sides inwardly curved—or "below grinding"—which is carried to its extreme in razors, lessens the work of whetting, but tends to make the edge weak and incapable of withstanding hard usage.

On the grindstones or abrasive wheel the tool is brought to an edge somewhat more acute than is desired for the finished one; but, owing to the coarse-

ness of the abrasive used, it is too rough for keen cutting. The final edge is "set" by rubbing with or on a flat finishing stone of finer grit, making a new and sharply defined bevel as shown, magnified, at D.

All cutting edges are somewhat serrated, some being finished on a stone so coarse that the serrations may be seen with the naked eye, as that of the common scythe. Such edges are made to cut by a sliding action, like a saw, and, for that matter, even a rasp will cut much more readily if given a slight endwise motion.

## Strap Hinge vs. T-Hinge

By G. W. D.

**I**N deciding whether to use strap or T-hinge one should keep in mind the fact that, when the two are of the same material size—say six inch or five-inch—and of about the same cost, the T-hinge is about twice as strong as the other. A thing is only as strong

Fig. 1—Strap hinge

as its weakest part, and the weakest part of such hinges is the joint or that part of the flap which bends around the pivot. Both strap and T-hinges usually fail through the straightening out or bending of this part and, as will be seen by reference to the accompanying

Fig. 2—T-hinge

sketch this part is twice as wide in the T form as in the strap. In the T-hinge it is of the whole width of the strap as at A B while in the strap hinge it can be of only half that width, as C D.

## Cutting Keyways With a Lathe

By H. D. Chapman

**A**METHOD of cutting keyways with a lathe is pictured in the accompanying drawing. A blue center is made to screw in the lathe chuck as shown at A. The center is then placed in the tail stock of the lathe. The shaft is then placed on the center and the other

Cutting keyways with a lathe.

end in the chuck thus holding the shaft rigid while the keyway is being cut. A hole is drilled at either end of the keyway B. This gives the tool clearance while it is being machined. The lathe is geared up to a high pitch, the tool is set in the tool post, the lathe is started up, and the feed is then thrown in, thus feeding the carriage along the work. Of course a special tool is required to cut the keyway. A keyway can be cut in a lathe just as well as it could be in a shaper.

## Making a Socket Wrench

**M**OST mechanics will not take the trouble to cut out a socket wrench but this is easy enough when done according to the drawing. It is laid out on the steel for drilling. Six small holes should be drilled if the socket is to be a hexagon. These holes

Method of cutting out a socket wrench

will cut out the corners. Then one large hole is drilled in the center which will cut out nearly all the stock and should cut two thirds of its way into the small holes. Then there is but little chipping to be done after this operation, simply two small fragments, which are indicated at A.

# Inventions New and Interesting

## Simple Patent Law; Patent Office News; Notes on Trademarks

### Recent Improvements in Machine Tools—1

It has often been said and rightly so, that the perfection to which metal working has attained is one of the miracles of our era. In many factories throughout the country the various pieces of turned, milled, bored, planed, or ground in such quantities at such speeds and with such unflinching accuracy as to command the admiration of the observer. Yet in spite of this perfection there always seems to be room for further improvement. This is the first of a series of brief articles on recent improvements that have been made in machine tools.—*Barrow.*

Among the inventions which have recently added valuable changes to the highly developed art of machine tool manufacturing are: 1. Flowerhard and W. F. Zimmerman of Newark, N. J.

The device patented by these inventors is a machine for cutting the teeth of helical gear wheels, without imparting a differential motion either to the blank to be cut or to the cutter.

The advantage of this invention lies in the fact that a single direct connection is established between the rotation of the cutter and blank spindle, an advantage which is an essential feature in all generating mechanisms. A more perfect control of the feeding mechanism, both of the cutter and of the blank itself as well as of the relative ratios of rotation of the cutter and blank, is thus effected.

In the figure, the work table 2, adjustably mounted upon the frame 1, is provided with a revolvable work spindle 4 to which the gear wheel 5 is secured, whereby the gear blank 6 is centered and secured to the spindle 4. A worm wheel 7 is fastened to the lower end of the work spindle 4 and rotated by the worm 8 in engagement therewith. This worm is mounted in the bearings 9 of the work slide 4, and is provided with a gear 10 which meshes with a gear 11 adjustably keyed to the index shaft 12.

The index shaft 12, mounted in bearings at either end of the frame 1, is connected to the index driving shaft 13 by means of a compound train of change wheels 14, 15, 16, and 17 to drive the feed of the helical cutter 18. The stud 16, carrying the gears 15 and 18, is slidably arranged in the arm 17 to accommodate change gears of different diameters. This arm 17 is pivotally mounted upon the driving shaft 13, and is secured in the various positions by the bolts 22 to the bearing 21.

The drive shaft 13, which imparts motion directly to the gear blank receives its motion from the main shaft 25 (Figs. 2 and 3) rotated by the cone pulley 28 through the worm wheel 29 and the worm 27. The ratio of the worm wheel 29 and worm 27 must be equal to or a factor of the ratio between the main driving shaft 25 and the helical cutter so that for each rotation of the cutter the index drive shaft will make a complete rotation or a multiple thereof.

The helical cutter 18 is secured to the cutter shaft 12, mounted to rotate in the swivel carriage 33. The cutter carriage 33 upon which the swivel carriage 34 is mounted is vertically adjustable upon the standard 3, and is parallel to the axis of the gear blank. The swivel carriage 34 is secured to the cutter carriage 33 in any angular position in relation to the gear blank in bolts 35 in the stud 36.

The helical cutter is pivoted about the shaft 12 by means of the bolts 35 and T-slot 36, and a rotatable connection through the driving gear 37, pinion 38, shaft 39, level gears 40, 41, and 42 is thus secured with the cutter drive shaft 43 for any angular position of the cutter.

For reversing the direction of rotation of the helical cutter, the level gears 47 and 48 on the drive shaft 25 are operated by the yoke 49 and handle 50 to engage, alternately the level gear 46 on the cutter drive shaft 45.

The feed of the cutter parallel to the axis of the gear blank is obtained through the change gears 23 and 24 feed worm

gears are selected in accordance with the material of the blank and the angle of the helices and placed in position. The proper index change gears are next placed between the index driving and index shafts. The work blank is then adjusted by the screw 53 and the hand wheel 54 for the proper depth to be cut.

The teeth of the gear will then be cut

A single direct connection is established between the rotation of the cutter and blank spindle, an advantage which is an essential feature in all generating mechanisms.

A machine for cutting the teeth of helical gear wheels without imparting a differential motion either to the blank to be cut or to the cutter.

shaft 55, feed worm 54 and wheel 56, from the index driving shaft 13, which rotates in synchronism with the helical cutter. The feed screw 56 engages a threaded portion 57 of the cutter carriage 34 and is rotated by the feed worm wheel 58.

To arrange the apparatus to cut helical gear wheels with a helical cutter, the gear blank is mounted upon and secured to the work spindle, the cutter is secured to the cutter spindle, and the swivel carriage is adjusted to the proper angle with relation to the gear and according to the angle of helices to be cut, and is secured in such position by bolts. The change feed

face of the cutter across the face of the blank

(To be continued.)

### Prizes Offered by German Engineering Societies

THE Verein Deutscher Maschinen-Ingenieure offer a number of prizes, as follows:

I. A prize of 1,500 Marks for an investigation of the causes and means of prevention of street noises due to railways and street railways.

II. A prize of 1,500 Marks for a thesis

on modern systems of steam heating for railway carriages.

III. A prize of 1,200 Marks for a thesis on modern lifting devices in use in locomotive works.

IV. A prize ranging up to 4,000 Marks for the design and computation of springs for railway carriages.

Readers interested in these competitions are advised to address further inquiries regarding details and conditions to Dr. Goebels, stalla des Vereins Deutscher Maschinen-Ingenieure, Lindenstrasse 50, Berlin, S. W.

### COMPETITION FOR MINER'S ELECTRIC SAFETY LAMP.

According to Electrical Engineering, a prize of \$3,250 for the best electric lamp provided with a reliable fire-damp indicator is being offered for competition in Germany by the Verein für das Bergbauwesen. The lamp is to be capable of giving a light of one lumen candlepower after burning for 12 hours, must be safe in the presence of fire-damp even if damaged. Three lamps with descriptions (in German), drawings, etc., in triplicate, must be submitted to the Verein, at Essen, before October 31, 1913. The judges will be a committee representing the Government, the Westphalian Miner's Association, and the Dortmund Mine Owners' Association.

### Automatic Gun Gun

By E. O. Carter

AN automatic gun is now being put to active service on the Clyde. The invention consists of a method of obtaining powerful explosions of a mixture of acetylene and air at regular predetermined intervals. The machine is at present made in two sizes, the cost of working being, respectively, about 4 cents and 6 cents per hour.

The writer when in Glasgow recently had the pleasure of hearing the machine at work, and the noise of the explosions was sufficient to take away any desire to hear the larger machine. A powerful acetylene gun has already been erected on a rock station off the west coast of Scotland, where it has proved itself much superior to the acoustic signals usually placed in such situations, as it is not liable to be exploded prematurely and is not open to the danger of being fired by lightning. Furthermore, it does not require the constant supervision of a keeper to put on charges and fire them, as it is entirely automatic. Once started it will continue until stopped. When the apparatus is fired on an isolated rock, and in other situations where a wire connection is inadvisable, it is intended to arrange that it shall be started and stopped from above by means of a small wireless installation.

The invention is thus admirably adapted for use on buoys and where expense and want of space on which to build prohibit the use of compressed air gun signals.

The present machine is the outcome of years of experiment covering a variety of gases, the mixture of acetylene and air having been found to give the best results.

The Death of James B. Hammond.—James Bartholomew Hammond, inventor of the typewriter that bears his name, died at St. Augustine, Fla., on January 27th. He had a varied career. Originally intended for the ministry, he graduated from the University of Vermont, and eventually entered the Union Theological Seminary. He soon gave up the idea of joining the church, and went to Germany, where he studied philosophy. He was a correspondent during the Civil War. As a school-hand reporter in a Boston paper, he first conceived the idea of his typewriter. It was this devoted the rest of his active career. He made a large fortune out of his invention.

### 1497 Vital Business Secrets

Here are the plans, the rules, the answers of business which put men right in their struggle for success.

If you only knew! If you could only realize that this offer places within your reach the knowledge which will straighten out snarls in your business life, make the way plain! Here are 1497 real money methods, proved by thousands of businesses for every business man, big or small, street meat or grocer, manufacturer or bookkeeper. Since the first edition, this remarkable Business Man's Library has been purchased by 36,463 concerns and by many of the greatest business men living.

One little sentence in one of these books may break down a barrier between you and success!

### 60-Cent Price the Result of 10 Years of Striving

A short time ago many thousands paid \$2.00 for a book similar to this one. But we have improved it so much that it is now worth \$2.00. It is a complete guide to the art of selling, and is a must for every business man. It is a complete guide to the art of selling, and is a must for every business man. It is a complete guide to the art of selling, and is a must for every business man.

# Mark Twain

1/2 PRICE

1/2 PRICE

THE AUTHOR'S NATIONAL EDITION has been issued to meet the most urgent appeal for a moderate priced set of all his writings. Formerly the cheapest set cost twice as much as the new edition, yet the Author's National Edition contains the same number of volumes and the same text, word for word, as the higher priced set.

Its paper and binding are of good substantial quality. The illustrations are by the same artists represented in expensive sets.

We believe that never before in the history of publishing has so good a set of the copyrighted books of a great author been offered at so low a price.

The price is possible because the popularity of Mark Twain assures a tremendous sale.

### Our Supreme Offer:

We offer you for 6 cents a day, less only four months, these 10 substantial volumes, published in an attractive light weight paper, full cloth bound, with covers in four colors—suitable for any library or desk. And this 6 cent offer on orders an 11-months' subscription to *Scientific American* (price \$1.00). That's \$9.00 only, in all, spread out thin over four months. Your check or money order or a dollar bill, under will start the books to you tomorrow, all transportation charges fully prepaid, and give you \$9.00 for eighteen months. Our dollar now and \$8.00 in month until \$9.00 is paid. (Worth of the Books, \$10.00). Long Canada, \$11.00. The first month is free. These books will last as long as you want to put into your pocket many times their cost. Send without delay as this edition is going to disappear the fastest of any we ever put out. Is the offer clear? There is nothing to sign.

Simply tear this ad out now, say "I accept your offer in *Scientific American*, February 8, 1913," write your name and address on a piece of paper, pin all together with your dollar and send to SYSTEM, Wabash and Madison Sts., Chicago.

SIXTY-NINTH YEAR

# SCIENTIFIC AMERICAN

THE WEEKLY JOURNAL OF PRACTICAL INFORMATION

VOLUME 57 (1913)

NEW YORK, FEBRUARY 15, 1913

PRICE 10 CENTS  
\$3.00 A YEAR

This sectional view, taken at the new City Hall station, shows the construction of the subway by the cut-and-cover method by which the material is excavated without any disturbance of the surface of the streets and sidewalks.

**BUILDING THE FOUR-TRACK SUBWAY BENEATH BROADWAY, NEW YORK.**—(See page 154)

## Engineering

**Refrillable Cords and the Right-horn Law.**—The Chief of the Bureau of Construction and Repair, Rear-Admiral R. A. Wait, states in his report that the average price per ton of normal displacement of the "Texas," "Nebraska," and "Oklahoma," which are being built under contract under the eight-hour law, is \$215.28. The average price of the three preceding battleships, built by contract when the hours of labor were unrestricted, was \$177.00 per ton of normal displacement, and for the first preceding vessels was \$180 per ton.

**Prosperity in British Shipbuilding.**—Just now the British shipbuilding yards are experiencing an extraordinary run of prosperity. The total tonnage of all ships under construction for merchant and navy service reaches the huge total of 2,400,000 tons, of which about 500,000 tons consist of warships for the British and other navies. In 1909, a period of depression 700,000 tons of merchant ships was built, or rather was under construction. To-day there is under construction 1,970,000 tons of merchant ships.

**To Dock the Largest Liners.**—The city of Boston is to be congratulated on its enterprise in appropriating \$3,000,000 for the construction of a drydock capable of taking the largest ocean liners. The construction of such a dock at New York has been the subject of much talk but little action. A 1,000 foot dock is said to be at any time most urgently needed. Had the "Titanic" been built in New York, it would have also been able to have had to stay here indefinitely, for there is not a dock in the country that could accommodate her.

**Surprise Signals for Locomotive Engineers.**—In view of the many accidents on the New York, New Haven & Hartford Railroad, due to engineers running by signals, the company has determined a series of test signals. According to a dispatch from New Haven, the tests will include improper train orders, displaced switches and a number of changes of signals. Tests of this character act as a strong inducement to strict watchfulness and obedience on the part of trainmen generally. The practice is followed on several roads, we understand, with excellent results.

**Porkin Medal for James Gayley.**—The Porkin Gold Medal was recently awarded to James Gayley, formerly first vice-president of the United States Steel Corporation. Gayley is the seventh recipient of the medal, which was created in honor of the William Henry Porkin the founder of coal tar chemistry, which revolutionized the dye and drug industry. The medal was awarded to Mr. Gayley for his invention of the dry-ash blast for the treatment of coke. The invention resulted in about a reduction of at least \$1 a ton in the cost of producing pig iron, besides making it possible for the iron master to produce in all weathers a product of uniform quality.

**The Selection of Locomotives.**—In the paper before the American Society of Mechanical Engineers in this city, Mr. O. F. Bover, Jr., speaking on the question of the selection of locomotives in relation to the economies of railway operation stated that the main steps in this selection may be divided into: "The consideration of the service, the nature of the business, the topography of the road, train speed, of train resistance, types and sizes of locomotives available, improvements to the permanent plant, effects of various types and sizes of locomotives on operating expenses, and the final selection of the most economical type and size of locomotive."

**Length of Piers at New York.**—On May 14th the world's largest steamship, the "Imperator," is laid at the pier 814 is 910 feet long. The longest permanent pier on the Manhattan side of the Hudson River are 826 feet long and these are leased by the Cunard Company. The White Star Company dock the "Imperator" at pier 814, which has been temporarily lengthened to 900 feet, but the extension must ultimately be removed. On the Jersey side the German Lloyd has a 900-foot pier. The Hamburg-American Line owns the "Imperator," having an 850-foot pier. To connect the big ship with the pier will be required to 950 feet. Secretary Rumson's recent decision provides for 1,000-foot pier.

**Cannibals as Battleship Protection.**—At a recent meeting of the Corps of Italian Naval Architects, Major-General Canibelli doubted whether the means of defense of modern battleships of the dreadnought type could be improved proportionally to the increase in their offensive power. He considers that a naval battle at ten thousand yards would demonstrate that gun-power was "vastly superior to the resistance of the armor protecting the ship's sides." He would concentrate the protection, but at the same time the difficulty of defense greatly increased. He considered that a naval battle at ten thousand yards would demonstrate that gun-power was "vastly superior to the resistance of the armor protecting the ship's sides." He would concentrate the protection, but at the same time the difficulty of defense greatly increased. He considered that a naval battle at ten thousand yards would demonstrate that gun-power was "vastly superior to the resistance of the armor protecting the ship's sides." He would concentrate the protection, but at the same time the difficulty of defense greatly increased.

## Electricity

**Electric Trucks in Boston.**—In 1902 the first electrically-driven delivery wagons were introduced in Boston. There were only two cars that year, in 1905 the number had increased to ten, in 1910 there were 100 such vehicles, and in 1912, 279, an increase in the last two years of 154 per cent.

**Installation of a Rocky Mountain Railroad Line.**—The Chicago, Milwaukee and Puget Sound Railroad is to electrify 450 miles of its main line between Harlow's town, Montana, and Avery, Idaho. The Great Falls Power Company which will furnish the electric power has received a fifty-year grant from the Department of the Interior to transmit current over public domain under street government regulations.

**Transmitting Range of Arlington Station.**—In order to determine the maximum range of transmission of the new wireless telegraph station at Arlington Va., the cruiser "Albatross" has been sent out upon a voyage over the sea. The cruiser will be used to keep in touch with the Arlington station and determine the exact distance or distances at which signals sent out from Arlington cease to be perceived. It is believed that the Arlington station will be able to transmit over a radius of 4,000 miles.

**Electric Service Table.**—A table has recently been put on the market which is of the ordinary library type but is also provided with four or more outlets or plug sockets, inconspicuously placed on the side below the table top. This affords means for connecting up electrical apparatus such as fans, cooking utensils, waste lamps, etc. An iron box secured to the under side of the table is a meter, main switch, fuse and the necessary wiring. Connection with the lighting main may be made through a steel conduit passing from the iron box through the baseboard to the outside of the building. This simple device comprises all the electrical outfit necessary for the electrical comforts of a living room. By using extension cords a vacuum cleaner may be efficiently employed all over the house.

**Electricity in the Drafting Room.**—Two applications of electricity finding connection with drafting work are contained in an English patent. The first is a use of a portable combination heater and fan ordinarily employed by handworkers to dry their customers hair after washing, to dry the ink on tracings. This "winkler" shortens the time required to complete the tracing as the freshly inked lines must be dry before T-square or compass work can be carried over the tracing. The second principle of the British idea the scheme might find considerable application. The other idea, which has been used in this country also, is to dry blueprints by going over them with an electric fan-blade, and the latter is also used to straighten out tracings and prints that have been full or folded.

**Mercury-Vapor Rectifier of Large Power.**—In the ordinary mercury-vapor rectifier using a glass vapor chamber the amount of electrical energy that can be converted from alternating to direct current has been limited, and the use of this form of energy converter has been confined to such comparatively small power applications as the charging of automobile storage batteries from alternating current at mains and similar light work. A recent German type of rectifier has been developed for converting larger amounts of power. The insulating vapor chamber is replaced by a gas-tight jacket is formed by a double coating of asbestos or similar material with a layer of mercury in between. A 220-volt, 80-kilowatt rectifier of this type has been in use since November, 1911 supplying the power for an arc iron furnace for 10 hours daily, the power being from single-phase 100-volt mains. A 100-kilowatt steel rectifier weighs only 1,000 pounds as compared with the 4,000 pounds weight of an ordinary rotary converter of the same capacity.

**Exploiting for Gas with Electric Air.**—During the excavation of the tunnel through the Santa Ynez Range in California for the Santa Barbara aqueduct so much gas was encountered that special means had to be devised for the protection of the workmen. It was decided to ignite the gas with electric arcs. For this reason arcs were placed in pockets in the roof of the tunnel, about 200 feet apart. Half an hour after the first blast was fired, the arcs ceased to glow, and by means of sensors it was possible to determine whether they were burning. If no explosion of gas resulted from this, the fire was entered the tunnel and proceeded a distance of 3,500 feet to the second working station. Here the current was again switched on, and if there was no explosion, he proceeded with his gang of men to explore the tunnel with a safety lamp in search for pockets. This done, torches were placed throughout the tunnel at distances of about 100 feet apart through the section in which the gas was encountered, and the men kept burning while the next shift was at work on the heading. Four hours were thus consumed in precautionary measures, between shifts.

## Science

**Solar Radiation Concentrated by Clouds.**—In the Bulletin of the Mount Weather Observatory, Messrs. H. H. Kimball and K. R. Miller call attention to the paradoxical fact that clouds, when favorably situated sometimes increase the intensity of radiation from sun and sky received by a body on the earth as much as 40 per cent over what would be received if the sky were perfectly clear, while increases of 10 per cent from this cause are quite common. This is shown by the records of the horizontally exposed (all under pyranometer, which was mounted on a pedestal representing the vertical component of the radiation from sun and sky, and the phenomenon is explained by the fact that radiation reflected from the cloud surface is added to that coming directly from the sun.

**The International Map of the World on a scale of 1 to 1,000,000** will be a completed sight or in a year's time seven or eight million copies of 140 feet by 7 feet or the surface of a globe 10 feet in diameter. It will consist of about 1,500 sheets each representing a section of 4 degrees in latitude and 6 in longitude. The first sheet of the United States portion has just been published by the Geological Survey in Washington. It is known in the general scheme as "sheet North K 10," but will be more popularly known as the "Boston sheet," and embraces Rhode Island, and portions of New York, Connecticut, Massachusetts, New Hampshire, Maine and Nova Scotia. It is a map of the United States, showing the terrestrial altitudes shown by contour lines and graduated tints. It represents the beginning of a more accurate map of the United States than any that now exists.

**Ozone for Preserving Meat.**—An important improvement in the technique of cold storage has recently been announced by German scientists. It is the use of ozone as a preservative to the ordinary process of refrigeration. In the cold storage rooms attached to slaughter-houses the temperature of the air is liable to be raised to a roomy extent when the doors are left open for any reason. For instance when the meat is being cut out or when the carcasses are being packed. The ozone is immediately become active under such circumstances and the keeping quality of the meat is diminished. Now it is known that ozone is a powerful germicide. If the air of the cold storage room is enriched with ozone, the bacteria which cause the decay of the contents. This has been proved by numerous experiments, and preserving apparatus has now been installed in the slaughterhouses at Olsone Potadam Brandt, Hamburg, Frankfurt-on-the-Main, Düsseldorf, Freiburg (Baden) and other places. The ozone is produced by a special device in Hamburg, and in various dairies, poultry and game stores and fish establishments.

**The Progress of Aerology.**—*Petermanns Mittheilungen* publishes an abstract of the presidential address of Prof. Dr. Hergewald at the tenth meeting of the International Commission for Scientific Aerology, held in Vienna, May 27th to June 1st, 1917. The commission has been the way has a misleading name as it is not concerned with the navigation of the air scientific or otherwise, but with meteorological investigations carried on with the aid of kites and balloons. The president in his report that since the commission last met, in 1909, twenty aerological stations had been added to the international network, including some in countries where no upper-air research had previously been carried on viz the Dutch East Indies, Argentina, Uruguay, Ireland and Canada. The commission has also observed the use of the upper-air balloon, one on the peak of T. M. T. and one in Spitzbergen. The former has made observations of the latitude and altitude winds up to an altitude of 11 miles by means of more than 400 ascents of pilot-balloons. The latter is a meteorological station on the mountain of the North Pole, especially in connection with various Arctic expeditions.

**Micrometer Positions of Halley's Comet.**—In the *Astronomical Journal* (No. 10, Vol. XXVIII) Prof. F. E. Barnard publishes some micrometer positions of Halley's comet made with the 40-inch telescope of the Yerkes Observatory. Prof. Barnard states that in the last few observations before its final disappearance it was exceedingly difficult to make the measures, partly because of the poor condition of the sky. Still Prof. Barnard is so accurate and skillful an observer that he has not undoubtably been accepted by every astronomer. The small field of the 40-inch telescope made it difficult to secure proper comparison stars on observations. Hence it was necessary in many cases to connect the comet with a faint star near it and then to compare this with a known star. The positions of the comet are given in the *Astronomical Journal*. Prof. Barnard also publishes in the *Astronomical Journal* a few notes made at the time of observation, and promises to publish in a later paper the main mass of notes. "These last gave a detailed description of the naked eye appearance of the comet, and I think," Prof. Barnard states "will be of service to astronomers at future returns of this object. No information seemed to be widely lacking in 1910 in connection with the return of 1835."

Fig. 4.—The same wave, photographed a moment later.

## Seeing Sound

### Snap Shots of Waves Traveling at Seven Hundred and Fifty Miles Per Hour

Our day on does not need to be a phylactery to know that wave motion of one kind or another plays an important part in nature and in technical applications of natural phenomena. The simplest and most obvious type of wave motion the one to which the name is primarily applicable is that which we observe in the ripple in a liquid surface—tension effect or in the undulating hills rolling on under the action of gravitation. Such waves are essentially two-dimensional at least their direction of propagation lies in a plane. A typical wave front in this case, such as that produced by a stone falling into a pond, is circular in form.

Other waves and a very important class, are three-dimensional (the typical form being spherical) each wave starting out from a point source and spreading out as a sphere with that point as its center. Light waves are of this character, as well as the waves used in wireless telegraphy. In fact as our readers know the two are propagated with the same velocity through vacuum and are identical in character except as regards their wave length which is of the order of one fifty thousandths of an inch in the case of light, and of the order of several thousands of feet in the case of the electric waves commonly used in wireless telegraphy.

While the circular waves on a sheet of water are readily observable and known to every child, it is only by special means that spherical waves can be rendered visible. Light waves are themselves of course invisible—contradictory as this may seem. A beam of light passing through a perfectly dustless space is absolutely invisible to an eye looking across the beam. In this sense it may indeed be said that no eye has ever seen a wave of light. But there is another kind of spherical waves—sound waves—which, though ordinarily invisible as waves of light, or electromagnetic waves, can nevertheless by suitable means, be rendered observable to the sense of sight. A particularly fine method for effecting this has recently been developed by Prof. A. L. Foley of Indiana University in collaboration with Mr. W. H. Snodgrass. By the kind permission of Prof. Foley and the courtesy of the editor of the *Physical Review* in which the first account of this method appeared we are enabled to give here an indication of the nature of the process followed and to show some of the very fine photographs obtained.

The method is best explained by reference to the diagram Fig. 5, which shows the apparatus employed. Four spark gaps  $N$ ,  $PA$ , and  $TA$ , are arranged in series in a circuit in which a large electric induction machine is included.

The gaps  $TA$ , serve merely as a means for producing a spark at the desired moment by turning the glass plates *out* of the way—these plates being normally interposed between the knobs  $T$  and  $A$ .

Very truly, a spark is thus caused at  $TA$ ,  $T$  and  $A$ , a similar discharge occurs at the gaps  $N$  and  $P$  also. The sound gap  $N$  is so arranged as to give a loud dis-

charge, thus sending out a sound wave consisting of alternate layers of compressed and rarefied air. The gap  $P$ , on the other hand, has its terminals made of magnesium wire, so as to give a brilliantly luminous discharge. The Leyden jars  $K$ , together with other features that cannot be discussed in detail here, serve to delay the discharge at  $P$  so that it occurs by a minute fraction of a second later than that at  $N$ . Hence the light from  $P$  arrives at  $N$  when the sound wave has traveled a certain distance out from its source. A photographic plate (for the observer's eye) is placed at  $P$ , and as the layers of air of different density of which the sound wave is formed, have different refracting powers, the appearance shown at  $P$  is that of a dark ring on a light background.

The waves produced by this apparatus are not strictly spherical in form, but consist of cylinders with hemispherical ends. As these are viewed end on, however, the appearance presented is exactly the same as if we were dealing with spherical waves.

Of the photographs so obtained we reproduce a few typical examples. Fig. 1 is a broadside view showing the cylindrical form of the wave. A simple transverse

Fig. 5.—General view of apparatus employed in photographing sound waves.

section is shown in Fig. 2. Very interesting is the wave which shows the appearance presented when the wave hits a reflecting plane obstacle (a mirror). The forward part of the wave (on the right) travels on unchanged but a similar secondary (reflected) wave is produced at the reflecting surface and travels out in pursuit of the original wave as seen in Fig. 4, which represents the state of affairs at a slightly later instant.

The action of a lens (sulphur dioxide contained in a collodion envelope) is shown in Fig. 6. It will be seen that the wave starting from the focus of the lens on the right, emerges as a plane wave (parallel rays) on the left. A similar effect produced by a parabolic mirror is shown in Fig. 7. Here also the wave emerges after reflection as a plane wave. A very interesting case is shown in Fig. 8. A wave starting out from one focus of an ellipse (at which the knob of the sound gap appears) is reflected and brought to a point at the other focus of the ellipse. Finally, a very fine interference pattern is produced, as shown in Fig. 9, by a cylindrical grating placed in the path of the sound wave with the source at the center.

It may be remarked that more recently Prof. Foley has further extended his researches, using the method here outlined, for the study of the electric spark discharge.

Those of our readers who may be interested in the details of the experimental arrangement designed by Prof. Foley will find a full account of these in the current issue of the *SCIENTIFIC AMERICAN SUPPLEMENT*.

### The New Campanile at Venice

THE new campanile of Venice shows some interesting points of construction. When it was decided to rebuild it, the principal question was to provide against a repetition of the catastrophe which befell the original tower. It is known that Venice, constructed as it is upon the lagoons, gives a very defective foundation, and this appears to be the reason why the old campanile fell down, owing to the overloading of the foundations. In fact, the tower had 250 feet weight and over 15,000 tons weight, and gave a pressure of 14 tons per square foot upon its foundations. In erecting the new tower the commission provided for better conditions by strengthening the foundations and at the same time lightening the weight of the construction by another method of building, also by consolidating the different parts of the tower so that there is no danger of dislocation. Redoubtable came in very well to carry out these ideas, and it enabled the engineers to give more space to the interior without changing the outside appearance in the least. The side walls are now very well joined together by means of the spiral staircase which passes up through the center of the tower so that the whole mass has a much greater solidity than before. The use of reinforced concrete allowed of reducing the thickness of the walls considerably and the new construction now has three quarters the weight of the old one. For the foundation over 1,000 new piles were driven so as to make it much stronger than before. The piles uphold a foundation base in hard stone, and the load upon the ground is now reduced to 47 tons per square foot, which is well within safe limits. The spiral staircase terminates in a large part in the destruction of the former tower, and that they will now be overthrown to a great degree. On the whole, the builders used great pains not only to keep the outside appearance of the tower as nearly like the old one as possible, but to reduce the body of the construction on the most modern principles in order to obtain the greatest possible strength, and thus diminish the likelihood of any similar accidents in the future.

## Co-operation in Educational Effort

THE recently issued annual report of President MacLaurin of the Massachusetts Institute of Technology discusses the need of co-operation in educational effort. To the students and alumni of the Massachusetts Institute of Technology the question is one of great importance in view of the proposed merger of the Institute with Harvard University. Admittedly there has been much friendly co-operation between Harvard and Technology, and prophesying an even closer relation in the future, now that the Institute is about to move to Cambridge, President MacLaurin nonetheless maintains that with regard to schemes that might be proposed to meet the actual conditions at Harvard and Technology, it is impossible to maintain extended co-operation with any satisfaction to either institution, and consequently with any chance of permanence unless the idea of competition is eliminated. Furthermore, he maintains that extended co-operation to be worth much consideration must be broad enough to throw upon the resources of both institutions (in equipment as well as in men) to at least some of the students of the other. He also insists that the obvious way to co-operate is in the treatment of the graduate students, leaving the greater part of the Massachusetts Institute of Technology on their own.

The necessity for co-operation in educational effort is nowhere more apparent than in the relations of technical institutions to our universities. Education suffers in few ways so much as through lack of co-operation among the colleges, universities, and schools of applied science which are now doing so much laboring together for the common good, not only should be avoiding by agreement those duplications of resources and of effort that keep them all ineffectually poor but also should be devising some plan by which waste should be transferred from one to another without loss of time and effort.

A few examples may give definitions to these general statements. If Harvard were to duplicate the complete mining and metallurgical laboratory which the Institute of Technology is planning to build and equip, the community would be called upon to expend hundreds of thousands of dollars for more duplication, and yet all the students of mining and metallurgy at Harvard could easily be accommodated in the Institute's new laboratory without detriment to the Technology students. Similarly it would be fully for the Massachusetts Institute of Technology to spend hundreds of thousands of dollars to duplicate the University's museum, whose great collections of minerals and fossils might be opened to the senior students at Technology without inconveniencing the regular students of Harvard. The building of an experimental tank in the Institute of Technology a step considered by competent authorities to be a necessary part of a department that is fully equipped to advance the science of shipbuilding would suffice very readily for two or more neighboring institutions.

Such duplication, however, does not represent the entire waste of the present system. More serious than any duplication of machines," says President MacLaurin, is the loss that falls upon the community by excluding advanced students of each institution from the benefit of coming under the influence of the pioneers of science in the other institution, men whose character and attainments make any suggestion of duplication absurd. For years the advanced students of geology at this Institute have been stimulated by Prof. Doherty's skill and enthusiasm as a teacher as well as by his scientific achievement. Now that he has left to Harvard, it is regrettable that such students should be cut off from his influence, especially in view of the fact that the advanced students of Harvard and Technology together would not be too many for a man of his capacity to deal with effectively. Indeed, in such cases there is a loss rather than a gain in efficiency, merely from the educational standpoint, where the number of students is unduly small.

President MacLaurin's discussion of efficiency in education was rendered necessary by the decision that there can be no merger with Harvard. The Institute seems strong enough to stand alone or to enter, if it wishes, into relations of co-operation in educational effort. Because the latter term might be misunderstood, and serve for a cause of division, President MacLaurin laid down the broad fundamental principles of co-operation with Harvard.

**Anomalies in Automobile Terminology.**—Automobile terminology, to many of those who are themselves engineers, must be a despair if their terms as used in relation and the naming of parts can be taken as a guide. Despite the evident redundancy, apparent in the derivation of the word "pedal," "foot pedal" is one of the most common of words that appear in nearly every automobile manual and advertising, while one "engineer" who would be more than ordinarily explicit has advertised that the brake is operated by the "right-hand foot pedal."

## The Slit Camera

By Or Berlin Correspondent

THE slit camera, designed by Mr. Wolfgang Otto, of Kiel, Germany, is an ingenious device on the pinhole camera type and is intended for producing any distortion desired. It comprises on the side turned toward the object, two crossed slits arranged in partitions situated behind one another. The slits may be straight or curved, of any width desired, and the distance of the partitions from the plane of the image may be varied at will. The partitions may also be curved or slanted if desired. The camera can, of course, be designed at will as folding camera or bellows camera, etc.

The Otto slit camera for producing distorted photographs.

Block of houses fore-shortened vertically by the slit camera

The same block with vertical lines exaggerated in length

Deformation produced by the use of slanting slits.

In order to make the fundamental principle clear we shall consider the case of a camera comprising straight slits of uniform width, the plane of the image  $A$  and the partitions  $B$  and  $C$  being vertical, while one of the slits ( $p$ ) is horizontal and the other ( $r$ ) vertical. The picture of the object  $o$  and  $o'$ , which is then projected in a horizontal and vertical direction, respectively being to one another the same ratio as the distances of the two slits from the focal plane.

If we follow a moving point along the line  $o$  of the object at  $D$  (Fig. 2), the beam of light passing from such point to the image screen at  $A$  will, as it were, pivot about the slit  $p$  in the partition  $C$ . Similarly if the point of the object considered moves horizontally along  $o'$ , the corresponding beam of light will pivot about the slit  $r$  in the partition  $B$  and the same applies to the horizontal beam of rays represented in Fig. 3.

Thus vertical lines of the object are thus gathered into an image at  $A$  by the slit  $r$  while horizontal lines are similarly gathered into an image by the slit  $p$ . Owing to the difference in the distances of the two slits from object and image, they form two images of different magnitude. But this amounts to saying that the resultant image represents vertical and horizontal features of the object on two different scales—or in other words the resultant image is distorted.

Other deformations may be produced by providing slanting partitions slits of varying width or curved. In many cases the conditions determining a given deformation can be found by calculation. Moreover, instead of a single slit any number of slits can be provided in the same plane.

The slit camera is not a mere scientific toy but can serve many useful purposes. Thus it may be used for rapidly altering architect's plans, or for producing comical caricature effects by deformation for carrying any given pattern for fabrics or carpets, and for altering the different forms of type.

The slit camera can be readily made in everybody and will be found an inexhaustible source of amusing experiment.

## Popular Ignorance About Our Common Woods

MODERN culture in its small measure despises natural history. Wood experts observe constantly from their intercourse with the farmer and the woodsman among the well educated people there prevails a general lack of acquaintance with the commercial woods. Among the wood users of the present day what knowledge they have upon the woods is actually that of a few superficial and unsorted facts, many of which, with a number of incorrect ideas concerning their physical properties and their suitability for certain uses. It is also a rather remarkable fact how prone people are to confound the names of well known species of woods, which, though closely related, possess not withstanding clearly marked distinctive characters. Thus, experienced lumbermen or timber merchants call spruces fir, pine spruces, aspens "scummers," and even trained foresters sometimes give the clear birch cedar (*Betula canadensis*) with our common red cedar or juniper. This confusion of knowledge exists also with relation to species which have been made familiar to a number of laymen in the local lumber yards where, for instance, western yellow pine is sold as white pine, and red oak as white oak.

There is no material in such common use as wood, and it may be from this very circumstance of its being so plentiful that it is looked upon by people as beneath their notice. The average man in the street is unable to tell the distinctive features of the wood of ash and that of chestnut, and he does not regard such facts entitled to any consideration. The same person would feel offended if he were told that he did not know the difference between a mushroom and a toadstool, or a matter of fact there is no botanical or other distinction whatever. A knowledge of the chief external appearance of wood and the far more prominent structural characteristics will be found upon investigation to be highly interesting and often proved to be of considerable value. It is a knowledge and understanding of the character of our common woods by which the relation of structure and external features is clearly indicated and defined, that the origin of many of our most useful and many possess the ability to group woods having like structural characters.

The study of woods has indeed lately received more attention than formerly as a branch of education and made a part of the course given in forestry and other technical institutions. It should be made a part of the common school exercises. But the teachers have themselves no very clear understanding of the character of the chief commercial woods, and a short course of instruction must first be introduced into our training schools for teachers. Instruction of this character can fitly be introduced in connection with study work.

There is hope that the coming generation will be better posted in the practical characteristics of woods. In this respect the people of Germany have progressed considerably more than the English or the Americans. The Latin names employed for a good many structures in wood have been perhaps the chief difficulty, and discouraged many persons from acquiring a better knowledge of woods. This difficulty is now fast disappearing, for older terms are being applied to such structures which are most essential to a knowledge of woods.

### Building a Four-track Tunnel Beneath Broadway, New York

**D**URING the 1940s, in Manhattan, and outside of it for that matter, the driver will long remember the intolerable discomfort which attended the construction of the present subway (tightly) subways stretched above sidewalks which tanned where once the street had been, sidewalks were littered with timber tools and the various impediments of the contractor, entire backed-up traffic, and the noise of the construction, and the possibility which though they may have stifled the inconveniences of the contractor certainly had no reference to the comfort of the street and sidewalk traffic. Dust in summer dirt in winter—obstructions everywhere, the four or five years spent in building the first subway developed a prejudice against the subway. The second subway, however, was a planned excellence for the first year or two of its operation to dislocate

We started with the lesson taught in 1933 and in recent years. In 1941 we are again building subway but we are doing it with many notable differences. The chief of which is that the many instances which accompanied the earlier work have been entirely abolished from the new work. Formerly a whole section of the street or if that particular neighborhood was not available, a whole block was closed down and a huge open excavation was maintained until the work had been carried down to the full depth. That was what the engineers called excavation by open cut. To do this our workers are built by what is known as the cut-and-cover method, which is being so far fully and successfully followed, that a large proportion of the millions of people that pass up and down Broadway and the other main thoroughfares of New York are cognizant of the fact that a four track express railroad is being built in a tunnel immediately below.

On the front pages of the present issue is a drawing which explains how this work is being done. The view is taken on Broadway at the point where the new City Hall Station of the new Broadway line is being constructed. South of the City Hall the route follows the streets to the west of Broadway; until it reaches the Battery when it crosses below the East River to a junction with the Brooklyn Rapid Transit System. North of it, City Hall Park the subway extends up Broadway to City Hall. From City Hall it branches off to the south through Avenue C, Fifty-third Street, where it will turn to the east through Fifty-third Street and cross the Queensboro Bridge to Long Island City.

The section of the work herewith illustrated, which is being built by the Degmont Contracting Company to whom we are indebted for courtesies in our examination of the work, extends from Walker Street to Park Place, a distance of about 2,400 feet. The tunnel contains four tracks as it approaches the station, which contains five tracks. Two of these are carried on an upper deck, the other three below the total depth of the excavation here being about 41 feet, and the total width something over 75 feet. The material is favorable for excavation being entirely sand, of which there are in this section about 230,000 cubic yards.

A most important work preliminary to the excavation, was to remove two gas mains 12 inches and 16 inches respectively in diameter, temporarily from the excavation and carry them above ground—this to guard against possible explosions due to leakage. The mains were diverted at each end of the work, and carried above the sidewalk upon temporary trestles as shown in the front page engraving.

The first operation in excavating by the 'cut and cover' method is to sink a series of shafts, placed generally on the side streets, just off Broadway. These shafts on the City Hall section were sunk at the 'Parade' and at North and White streets, and they were carried down to the depth of the first bench of the excavation, or say about 10 feet. The next step was to remove the street paving for its entire width and for a length along the street of forty or fifty feet, and lay down a series of parallel longitudinal 10-inch by 20-inch timbers, spaced five feet apart. On these was laid a roadway of 5-inch plank. The space between the two tracks was covered by two layers of plank one of 3-inch and the other of 2-inch thickness, and the whole was supported by upper layer longitudinal. When this was done a smooth roadway of timber was thus provided in place of the asphalt or Indian blocks.

The excavating gang then entered the side shafts and with pick and shovel began to excavate across the street. As the work advanced, they placed 12 by 12 posts beneath the 10 by 10 timbers which carried the roadway planking the excavation being carried on until it was completed to the opposite side of the street. Temporary footings for these posts were placed on the bottom of the excavation the transverse lines or bents of supporting timbers were placed ten feet apart, measured in the direction of the street.

The excavation and timbering, as thus described, was carried down to about the 16-foot level below street grade. Above this level, it will be remembered, the sup-

working points were placed at 10-foot intervals, below the character of the construction made it necessary to place the posts at 30-foot intervals. Moreover, it was impossible to reach the final bottom of the excavation, in place before the dirt was taken out. To do this, thin lashed shafts measuring 3 feet by 4 feet were sunk down to subgrade, and into them the 25-foot 12 by 12 post was driven. The shafts were placed at 10-foot intervals, and at the foot of each shaft, as a footing or foundation. At the top of the 25-foot posts were the cable and longitudinal stringers, upon which the upper and shorter lengths of posts rested and which served to tie the posts together. The system of framework was thoroughly braced, as shown.

The excavation was done by pick and shovel, the dirt being loaded into buckets, on small contractors' cars, which were hauled up the shafts by means of winding shafts either by mules or electric locomotives, where they were hauled up by electrically operated derricks and dumped into hoppers. The latter were built on platforms spanning the street or the sidewalk, which were supported by the posts. The material from the hoppers the contractor's carts, which carried it to the dump or wherever it was being disposed. The disposal of the material was one of the serious problems of the large-scale excavation.

Some very successful excavating was done by means of a belt conveyor and elevator. The conveyor extended across the cut opposite the hoisting plant, which was located in the shaft near the corner of Chambers and Broadway. The material was hauled in cars by electric locomotives, dumped into a hopper, loaded onto the belt conveyor, and carried to the foot of the elevator, whence it was taken up and dumped in hoppers upon the platform.

During the progress of excavation the sidewalls of the tunnel were protected against caving in by means of three lines of vertical sheet piling driven in as shown in our front page illustration. The piling is braced by a series of 10 by 10 struts, which are carried back and held against the longitudinal timbers of the 25-foot carrying posts already referred to.

When the excavation had been carried down to subgrade the heavy floor of concrete about 2 to 2½ feet in thickness was laid and the work is today no far advanced that the concrete floor is completed for a length of 300 feet.

An important and costly section of this subway building is the provision which must be made for supporting the front walls of the buildings which line the route of the tunnel. In the case of the more recent buildings, whose foundations have been carried down to rock, no change is necessary, but in the case of older buildings such as the Riccardi building shown on the right in the illustration, whose foundations were fairly shallow, the bottom of the tunnel excavation, it was necessary to dig under the underpinning.

Steel needle beams were run at intervals through the foundation walls, their ends resting upon timber posts of sufficient strength to carry the entire load of the front wall. Masonry was then built in below the wall until the latter continued without a break down to a point slightly below the floor of the subway.

It will interest the readers of the SCIENTIFIC AMERICAN to learn that the first tunnel below Broadway constructed over forty years ago, on the plans of the late Alfred Ely Beach of the SCIENTIFIC AMERICAN, was located at the point where the section shown on our frontispiece was taken.

Our thanks are due to Mr. Hurdette Klipp, assistant engineer, and Mr. H. P. Gustin, engineer in charge, for their courteous assistance in furnishing opportunities for the preparation of this article.

## A Feathering Air Propeller

IN the mechanical engineering laboratory of Columbia University a test was recently made of a feathering air propeller invented by Ciro F. Mendes. The propeller was eight feet in diameter and weighed 180 pounds. Of this weight 76 pounds was the weight of the blades and 117 pounds the weight of the hub and the mechanism for feathering the blades, a weight not excessive for a dithrich airship propeller.

In carrying out the test the propeller was mounted on a frame free to move in a horizontal direction by the action of the propeller upon the air. The amount of thrust was measured in pounds by a spring balance. Power was applied from an electric motor through belt in such a manner as not to effect the movement of the table, in other words, power was applied directly over the center of rotation, the weight of the frame of the propeller was carried upon anti-friction rollers, and the friction error was eliminated by measuring the power

including the friction and means the friction, adding these together and dividing the result by two. A series of runs 165, 200, 220 and 300 revolutions per minute were made and the amount of current and thrust recorded. After the capacity of the apparatus had been learned, a brake pulley was attached to the propeller shaft and arrangement made for reading directly the amount of power transmitted to the propeller. In this series of tests, the propeller was driven at each of the speeds referred to and the readings of the voltmeter and ammeter recorded, also, the thrust of the propeller. Then the coupling in the line between the motor and the propeller, the brake pulley and the brake attached, and the motor, the same reading of the voltmeter and ammeter, thus determining the actual power delivered to the propeller and eliminating the electrical and mechanical efficiency of the motor, belt and shafting.

### Molecular Structure and the Origin of the Elements

CONCEIVED in the mind of ancient Greek philosophers, the atomic theory of the "grained" structure of matter was revived in 1803 by John Dalton to account for the fundamental law of chemistry, according to which every compound contains a definite and invariable proportion of its constituent elements. But the atomic structure of matter interests the physicist quite as much as the chemist for he is not, according to the kinetic theory, the impact of gas molecules against the walls of the containing vessel which causes the gas to exert a pressure on those walls?

And here a pressure on these walls? But the pressure is not directed to look at the matter, but to look at the molecules. But while these qualitative conceptions of the grained structure of matter are comparatively easy to grasp, it is not so easy to grasp the quantitative conceptions. The highest scientific genius to develop the mathematical theory and to enable us to calculate the size of hydrogen molecules, of which forty two million millions could be packed into the volume of a single blue cupric sulfate crystal, and to enable us to calculate the size of the molecules, but to have rendered visible to the eye that very dance of the molecules, but to have actually counted them one by one (take advantage of the flash of light which is emitted when a molecule of a substance is excited and then shot out from a radio active substance against a semi transparent screen) And here the phenomenon of the grained structure of matter brings us face to face with another question: how can there be different kinds of atoms, how can there be different kinds of molecules, how can there be the oxygen atom, for example, being invariably sixteen times as heavy as the hydrogen atom? Radium seems to hold a clue to this problem. It appears that the atoms of the elements are not stable, but that they are continually undergoing disintegration, each atom of such element splitting up into others of lower weight, and then another product of the disintegration of radium is another element, and so on. It is known beyond doubt by Raman, Butherford and others.

Have we then achieved the transmutation of the elements? Yes and no—yes, for radium is transmuted into helium and other products, no, for we have no control whatever over this exceedingly slow transformation.

This was but yesterday. To-day, if first accounts received prove authentic, we may answer our question with an unqualified "yes." For we read in the daily papers that Mr William Ramsay and Professor Norman Collie and H. Patterson have found newly formed helium and neon in bulbs originally containing hydrogen at a low pressure, and submitted to the influence of an electric discharge. This, then, so far as one is able to gather at the present moment, seems to be a definite case of transmutation (if not of creation) of elements under controlled and irreproducible conditions.

## The Art of Making Bronze Statues

From the Raw Clay to the Finished Figure

By C. E. Fairbanks

THE artist who portrays his conception in bronze encounters many obstacles which his brother of the plastic art can never see his way to surmount with. Among other difficulties is the fact that the work of the former has to pass through several hands other than his own before completion, whereas the work of the latter is begun and finished by his hand alone.

In giving expression to his conception the sculptor frequently works it up from a minute model in the rough which but faintly suggests the portrait that he is to show larger and more detailed until finally the model for exhibition is finished. This model while reproducing all the details may be much smaller than the desired size of the final work—especially if this is to be life size or heroic. For working material the sculptor uses either wax, modeling clay or some special composition which in addition to being plastic will retain its shape indefinitely and support a very considerable weight. To avoid excessive use of clay but principally to stiffen the figure, a skeleton framework is constructed and is known as the armature.

Fig. 1 shows the armature for the whaleman with pedaled harpoon—in the New Bedford (Mass.) Whaleman Museum is R. L. Pratt's. A pointing machine, consisting of a vertical stand with a multiplying horizontal arm is used to transfer from the accepted model and locate on the armature such points as nose, chin, knee, etc. as this framework is assembled. The clay is then plastered on roughly and afterward shaped to a finish as is shown in the view (Fig. 2) of R. L. Pratt's studio, at the left being the figure of "Art" for the Boston Library with the clay roughly plastered on the armature in front of it being the pointing machine. At the right Mr. Pratt is finishing off the figure of "Science" with its front statue the woman model.

After all finishing, touches have been put on the sculptor turns the clay portrait over to the plasterer and man, who mold about it a shell of plaster of Paris. This shell is then removed by lining sharp metal plates about 4 inches square along certain lines depending upon the contour of the figure, and by this means splitting the shell into sections, which on this it is to be removed with. The shell is then reassembled and as this process is such framework or unlike the original armature is built up inside of the reassembled shell, extending being used to fill any openings in the framework. To prevent the sections pulling apart the entire shell is either bound up securely with wire or is covered in sand. Liquid plaster of Paris is then poured in through an opening at the top and the shell filled—the interior framework serves the same purpose as the armature of the clay model. After removing the shell we have to plaster a duplicate of

the original clay portrait. For proper molding in the bronze foundry it is invariably necessary that the plaster cast consist of from two to twelve or even more parts as the contour of the figure may dictate, that is the head, one or both arms, the base and other parts must be removable so that they may be molded separately. This end is attained in one of two ways. When the plaster cast is made, those members which should be removable are made separately and fitted into a socket cut into the body of the figure or else at the foundry those members are sawed off, a protrusion is built on the end of each member and made to fit into a socket cut into the body at the point of amputation

thus forming, when assembled, a socket joint. In making the plaster cast of Lincoln (the finished bronze is shown in Fig. 11) the left arm, the right arm, the legs, and the head are all removable. In the accompanying illustrations the manner in which the various pieces are separately molded is very clearly shown.

When completed the plaster cast is then delivered to the foundry, and here the requirements are so exacting that a combination of skill and patience is necessary at every step. In the foundry the molding is done in dampened sand imported from France which is not unlike very fine clay in texture and can be packed quite hard. It has the quality of retaining the finest lines of an impression, and will neither flow nor burn when in contact with molten metal. In the simplest pattern the containing box for the entire mold is made in two halves—an upper and a lower—and is known as a "flask." In the complicated molding of a statue the flask may consist of any number of iron sections held together by clamps, each section supporting some portion of the mold.

After separating the plaster figure into its various component parts they are dusted with sawdust. Starting with the body of the figure or largest portion, it is laid in that position which enables it to be most easily withdrawn from the sand. The molding sand is packed solidly and carried as high as the contour of the figure will permit of easy withdrawing. The surface of the sand is then dusted with plumbago or similar substance to prevent adhesion of the succeeding layer, an additional section of the flask is put in place, sand again packed in and carried higher on the figure, as shown in Fig. 4 and so on until it is entirely covered. It invariably happens that the surface of the figure is so complex that blocks or sections of the sand have to be arranged to move horizontally away from the plaster cast when disassembling the mold. In Fig. 4 the section in front of the face is of this type. Also, the removable sections of the plaster cast are either molded separately, or put in place as the molding of the figure reaches that point as in Fig. 7, where the head of the statue has been added.

In spite of the fact that the sand packs hard and sustains quite a weight it is necessary, when the surface of the mold is of considerable area and irregular in shape to stiffen it with a framework of iron pieces roughly fitted over the outline of the surface and wired together as shown in Fig. 5. The sand is then packed in place and the form completed as in Fig. 6. Fig. 8 also shows the line of separation between the upper and lower molds.

After the entire plaster cast has been

Fig. 4.—Packing in sand and building up the flask.

Fig. 5.—Lincoln torso immediately after casting

Fig. 6.—The torso after superfluous metal has been cut away

covered or molded, it is then necessary to remove every section of the mold in order that the figure may be taken out. Since a mold casting would add both unnecessary weight and cost without in any way adding to the appearance, it is made hollow.

To do this the various sections of the mold are reassembled, and as this progresses the space formerly occupied by the figure is packed with sand, forming, when completed, what is termed the "core." This same reason that applies to any other large section of the mold requires that a framework of iron with projecting studs for supporting and handling be built in side the hollow space as shown in Fig. 4. When the "core" is completed the mold is once again taken apart and the "core" removed. It is to be remembered that this entirely filled the space formerly occupied by the plaster cast figure, hence, in order to provide space for the metal the entire surface of the core is shaved away to a depth of about one quarter inch, thereby allowing this amount of space between the core and the mold, as can be distinctly seen in Fig. 9 and it is into this space that the molten metal will flow.

The projecting pieces of the iron framework of the core, which rest upon the mold body, hold the core away from the sides of the mold. These projecting pieces can be seen in Fig. 9, where they serve the additional purpose of handling the core. A vertical hole or passage way is provided starting from the bottom of a reservoir on top of the completed mold and connecting with numerous horizontal runways at different depths, which reach various parts of the mold so that the molten metal may reach all points of the mold as soon as possible. Some of these runways can be seen in Fig. 9.

The slightest trace of moisture in the core would become converted into steam and ruin the entire figure when the molten metal came in contact with it, hence, to avoid this the various sections of the core are loaded on a car and carried into an oven where for 24 hours they are kept at a temperature of from 500 deg. to 700 deg. Fahr.

Then for the last time all portions of the mold and core are carefully reassembled, vents are provided for any gases liberated, the sections of the flask are secured clamped together, a clay lined reservoir is placed on top so that a large amount of metal can be collected, and it is allowed to run into the mold, and all is ready for the crucial moment when the powerful crane will lift the big iron bucket holding 2,000 pounds of molten bronze and amid peal of excitement will begin the pouring which will determine whether success or failure will crown the painstaking effort of weeks and months.

Fig. 1 shows the completed flask with reservoir all ready for the pouring. Bronze is an alloy of copper, zinc, and tin. For statuary work the mixture usually consists of 90 per cent of copper, 3 per cent of tin and 7 per cent of zinc although the proportion of tin and zinc is varied to suit conditions. Any of several colors may be given bronze by proper acid treatment, although the natural color gives a better effect, and is generally used. When the metal has cooled sufficiently the sand is broken away from around it, the casting removed, thoroughly washed, and the core removed by washing and cutting. The figure has somewhat of an uncouth appearance, as seen in Fig. 5, in which the projecting parts of the core are seen and the runways are represented by the grape-like effect. All superfluous metal is cut away, an acid bath is given for further cleaning, and the bronze figure now has the appearance seen in Fig. 6. It is now carried to the finishing room, where all of its parts are assembled and permanently fastened in place, any seams being welded together with pneumatic hammers. After a careful inspection and retouching the statue is completed as seen in Fig. 11. It is now ready for its final

Fig. 7.—The head of Lincoln was put in place as the molding of the figure reached that point.

rolling place, where it will remain through generations to come a perpetual monument and reminder of the greatness which once helped make history.

By far the greatest number of statues are of army officers. Statuesmen come next, representatives of the militia are sometimes perpetuated in bronze and away down the list come the navy officers. This may be because the greatest number of our important battles lay up to and including the civil war were fought by the army. Hence the greater number of prominent officers are of the army or it may be that we have been somewhat slow in perpetuating the memory of our more less valiant and important heroes of the navy.

### Generating Current at the Mine

THE cost of power for lighting and manufacturing purposes depends generally on the cost of fuel and the cost of fuel in most cases is determined by the freight rate, or transportation charges from the point of production of the fuel to the center at which the power is required. Successful efforts have been made in Nova Scotia to transport power in the form of electric energy from a colliery to neighboring centers, thus avoiding freight rates or reducing these rates to an amount equal to the loss in electric transmission plus interest on cost of transmission line.

At Chatham the central station is located and the district is supplied from this point. The central station is originally equipped with an 800 kilowatt generator, direct connected with a vertical engine crank cross compound in gear running at 100 revolutions per minute.

This plant was installed primarily to make a market for some undesirable refuse from the colliers, but the success met with was so marked that additional units were installed. The plant now has a capacity of 1,500 kilowatts and is running with an overload with plans are being prepared for installing an additional 1,000 kilowatt unit, contracts having been placed for the disposal of the greater part of this additional power.

The power station is located one hundred feet from the bankhead at Chatham colliery and connections are arranged that the fine culm which passes through the screens and crushed refuse which is picked from the screened coal in passing over the cleaning belts, is conveyed directly to overhead storage pockets in the boiler room of the power plant. This fuel contains 25 per cent ash and is fed by gravity into mechanical stokers.

The current is transmitted at 11,000 volts, 4 phase, 60 cycle and is utilized at Amherst colliery mine from the central station, for general factory purposes and the entire lighting of the city. At Napton the gasworks operates their derricks and pumps.

Collieries at Ingleton Mines, fifteen miles from the central station are operated mostly by electricity, and the venting, pumping and coal cutting machines are all motor driven.

River Harker is a thriving farming community the farmers of which utilize the cheap power available to their own advantage for milking apparatus, churning, etc. At the other pole touched by the transmission line the power is chiefly used for lighting purposes.

This project has been brought from its small beginning to its present successful state under the direct supervision of G. D. Burhill a consulting mining engineer of Montreal, Canada.

**American University in Siam**—Under the auspices of the American Presbyterian Mission in Northern Siam a university is in process of development at Chiang Mai. It is expected to absorb the Prince Royal's College as the college of arts, in addition to which there will be faculties of sciences, medicine, and theology.

## Parabolic Overhead Wiring for Electric Roads

By Owen M. de Munick, C.E., E.E.

THE construction of overhead wiring for electric traction has undergone considerable alterations during the last few years, alterations which were to be expected owing to the great extensions of railways

suspended in a movable manner. The parabolic carrying wire, with the parallel wire above the conducting wire, as used on the New York, New Haven and Hartford Railways, are not movable, they are thus subject to the influence of the temperature, sagging and sagging in cold weather and shortening with increased strain in cold.

quite exact enough to find it in the way described below. A little wooden post is erected in the middle between the two masts, three movable bands are fitted to this post. The top one is level with the disk on the mast, the other two bands giving the theoretical drop of the two wires. When this is finished complete section from one pair of weights to a new pair of weights

Diagram showing the method of straining the cables so as to prevent sag

Detail of the support at one of the bridges.

and tramways and to the increasing speed. The existing construction did not meet the latest requirements, and the chief factors which led to the reconstruction can be considered as the following:

- I The application of high tension attracting car rail for traction purposes.
- II The necessity of a minimum sag of the conducting wire at high speeds to insure an even contact of the low (trolley).
- III The necessity for equalizing the conducting wire in a non-rigid manner due to the fact that each rigid point jars the contact bow (trolley) causing it to spark also imparting a tremulous motion to the bow (at high speeds) resulting in a series of sparks.

To meet the above requirements it was useful to provide a new means of hanging the conducting wire above the track. This was found in the catenary system which permits of the conducting wire being suspended at short intervals and in quite a yielding manner. Such a system exists in Holland on the Hago-Lelystad Katwyk Noordvijk and Rotterdam The Hago-Scheveningen. The last mentioned line possesses the peculiarity that the influence of the temperature is neutralized by means of weights which give a constant strain to the wire. This conducting wire is, of course

To avoid this drawback a system was contrived by the A. E. U. Company by which all wires are made movable.

During a number of years they have made different trials along these lines on their experimental railways at Lelystad and Hago. This extensive trial has resulted in a system that was adopted by the 'Ipsodon State Railways. In 1910 the line Donsen Bitterfeld (steam railroad) was partly equipped with this system, the other part being carried out by the Siemens-Schuckert Company (the same system as the Rotterdam The Hago-Scheveningen which was constructed by the same [A. E. U.] company).

Donsen Bitterfeld is only a trial line, as plans are made to electrify the whole steam road from Mangleburg Lelystad and Hago. This extension will be very important, as the newly constructed part is only 27 miles long and rather too short for making long distance trials at high speeds.

In the accompanying drawings of the A. E. U. system, showing three spans of the overhead line and the method of suspension on a cross girder. 1 is the strain wire, 2 parabolic suspension wire, 3 conducting wire, 4 vertical suspension wire, 5 and 6, are clutches. If the loop formed by 4 and 6 passing below the cross girder 3 is a flexible wire to which the insulators 7 and 8, are attached. This wire connects the clutch 5, with 6, and brings the strain over from one side to the other as the loop 4 is hanging loose. This flexible wire 3 is insulated between the insulators 7 and 8 and rests on the diaphragm insulator 9 on the cross girder. Two nuts 10 and 11 are fixed on each side of the insulator 9, which prevent the flexible wire 3 from moving to the right or left under the influence of the temperature. Galvanized clutches are used to join the wires together where necessary, as an connection was made by soldering.

The insulators are so made that in case one of them breaks the whole system cannot fall as the two wires are hooked inside the insulator. The strain wire 4 is provided to assume a regular stretch of the parabolic carrying wire over the whole length from the fixed point to the weights. This strain wire, of course has very little sag. The clutches 5 and 6 join the strain wire and the parabolic suspension wire at each suspension point on the mast, bringing their strain over on the flexible wire 3. The loop formed under the cross girder by the two first mentioned wires is necessary in case an after regulation of one of the wires is needed. The working of the system is as follows:

When the temperature is increasing, the parabolic carrying wire 3 will expand, thus increasing the sag or in other words decreasing the strain. The strain wire 4 will expand to about the same extent, being made of the same material (galvanized steel cable). Its strain will also decrease, and, as it has very little sag, its strain will decrease considerably more than that of the parabolic wire. The weights at one end, and pull with a constant strain, and thus stretch both wires until the strain is balanced, when the drop will be exactly the same as before, since for a certain constant strain there is always a certain constant drop. By a decreasing of the temperature an opposite action will take place. The same happens to the conducting wire, as it is connected to the same weights at the end. Near these weights is a lever 12 to which the three wires are joined, and a flexible wire bringing their strain over to weights on the mast. This lever is necessary because the strain wire and parabolic wire are made of steel, while the conducting wire is made of hard bronze. These have different temperature coefficients, which this lever neutralizes.

To start the building up of the system little hooks are fixed to the masts at each side of the railroad (about two meters above the ground). On these hooks is provided with wheels the flexible wire 3 (already fitted complete with the insulators and clutches) is laid, and the strain wire and parabolic wire are fixed to this flexible wire and the required drop of both wires regulated. This drop can be measured by means of a strainometer (measuring its strain), but it is easier and

of about 1000 meters), is ready. The vertical suspension wire can also be fitted. The conducting wire is hung on these wires (after being stretched on half its normal strain). When the whole system is ready it is pulled up by block and tackle over the whole length of our section and placed on the diaphragm insulator in the center above the track. It is always necessary, of course to inspect the system after it has been placed in the proper place, by means of a tower wagon.

## A Comparison Microscope

By Dr. Wilhelm Thiesner

THE manifold demands and wishes of workers in every field of scientific and medical research have been met by instrument makers, very successfully, as a rule, by improvements in the mechanical and optical construction of the microscope and its accessories. It is the more remarkable therefore that no instrument has come into general use for the simultaneous observation and direct comparison of two microscope objects. Such an instrument which may be called a comparison microscope would render very valuable service in a great many scientific investigations. In testing articles of food for example it would often be

A comparison microscope.

### The Mono-rail Sled

A NEW type of sled has put in an appearance recently which should delight the heart of every small boy. The object which will first catch his eye is a steering wheel, a real live steering wheel, just like that of an automobile, and it controls a steering runner placed in advance of the two main runners. But even more interesting than that is a fourth runner placed between the main runners (naturally this does not come into play). But after the power coaster is well started down the hill he pulls the steering wheel toward him, depressing the fourth runner, and raising the entire sled upon it so that he continues to glide down hill on two runners, arranged in tandem. This reduces the friction surface, enabling him to outstrip his rivals on the more clumsy type of sled. A certain amount of skill is required to maintain the balance on the center runner, so that the sled will run like a bicycle, and this adds interest and excitement to the sport.

Readers are invited to contribute photographs of novel and curious objects, and/or occurrences, and ingenious contrivances. Such as are found available will be paid for promptly.

A "mono-rail" coaster

Balanced on tandem runners.

### Turbine Casting for the Gatun Power House

THE accompanying illustration shows one of the three turbine castings recently made at Hartford, Connecticut for the power house at Gatun, Panama. The turbines will take water from the great lake formed by the Gatun dam and will drive electric generators to supply the power for operating the locks and towing the vessels through the locks and also for lighting the canal zone. The turbines will have to develop 1000 horse-power. The castings are made of a composition of copper, tin and zinc in the proportion of 88, 10 and 2. The alloy is required to show a tensile strength of 30,000 pounds an elastic strength of 15,000 pounds, and 18 per cent elongation. The castings weigh a little under 7,000 pounds. It will readily be appreciated upon examining the illustration that some very intricate dry sand core work was necessary to produce these wheels. The same cores, of which there were sixteen for each of the three wheels, weighed a little under 700 pounds each, and because of their peculiar shape, were exceedingly difficult to set.

Intricate turbine casting for the Gatun power house

### Benvenuto Cellini's Portrait of Himself

THE rear of the helmet of the famous statue of Perseus at Florence is cleverly designed to represent a face, with a beard formed by the curling hair beneath. Although this face has been known to exist for some time no attention has been paid to it. Recently, however, an antiquarian named Annaliese Benedetti discovered the face, and was struck with its marked resemblance to Benvenuto Cellini who made the statue. It is a curious fact that no reference to the portrait is found in the state archives or in any of the descriptions of this piece of work, nor even in Cellini's own memoirs of his masterpieces. The statue was ordered by Cosimo II of Medici, and the theory has been put forth that being jealous of the beauty that might come to Cellini, he would not permit the sculptor to place his name upon the statue. On the other hand, Cellini being a very vain man, could not give to the world this masterpiece, which took him nine years to complete, without identifying himself with it in some way. Hence, he adopted the daring and novel expedient of actually carving his own likeness upon the statue, so that for all future time there would be no doubt of its authorship.

By courtesy of the U. S. National Academy of Sciences.  
Portrait of Benvenuto Cellini, discovered on the helmet of his famous statue of Perseus.

### The Sleigh of the Desert

A CORRESPONDENT in the French army in North Africa has devised a peculiar machine particularly adapted for travel over the hard wastes of the Sahara. The machine is a cross between an automobile and an aeroplane, and has been dubbed the "sleigh of the desert." The construction is very light indeed. It is

The "grass-hopper" couch of the Sahara.

mounted on broad tired pneumatic wheels, but is driven by an aeroplane propeller. It is so light and its bearing surface is so great that it will ride over any sands without sinking, leaving over light depressions and climbing the steepest sand dunes. There is a decided advantage in using an air propeller for then the drive of the machine is independent of the friction. In the lower sand of the desert it would be rather difficult to propel a machine after the manner of an automobile. The accompanying photograph, which is published by the courtesy of *L'Illustration*, shows the odd machine upon its arrival at Touggourt having carried four Galland over a distance of about 120 miles. The peculiar vehicle is named La Sauterelle or the grass-hopper because of its peculiar hopping flight over the irregularities of the desert.

### Fish Killed by Frost and Storms

AN *Esquimaux* *Metropolitan Magazine* Editor D. C. Bates, London meteorologist chief of New Zealand tells of some curious effects of atmospheric disturbances on the fish. A deep-sea species known as the tooth fish (*Trachyrhynchus*) is found lying dead on the shores of the South Island of New Zealand during and after severe cold weather. It is a long slender silver fish with a blue line on its side and no scales at all. It is found in the water from very great depths and apparently are killed by the burst of the ice in the hands rather than by the cold, yet their number, the weather seems to be connected with the weather especially with meteorological conditions.

After severe storms the coasts of New Zealand are often strewn with tons of dead fish of many species. A correspondent of the author writes in regard to such occurrences at Island Bay Wellington on July 18th 1912. "This is not the first time nor the fourth time that fish have been landed on the shores of Cook Strait in precisely the same fashion in every case subsequent to a storm. Therefore, we must look for the cause in the storms, unless it is that storms may produce what we call fumes, or striking up the bottom of the sea immediately offshore we have comparatively deep sea in shallow by fishes which are not usually met on the immediate coast line. If from any cause during a high storm deep-sea fishes are blown to the land then it only requires a very heavy sea in which waves strike the bottom to bury the fish under their own weight and kill them in hundreds. After the storm of July 18th mentioned above at quantities of the dead fish—blue hake, hake, etc. were gathered and brought into Wellington. On another occasion some thirty years ago the beach at Okarito on the South Island was strewn for seventy miles with fish of all sorts and sizes.

### How to Wax Old Unpolished Floors

THE wax old floors that were never polished the following method is good. The floors should first be washed then scrubbed and then when dry coated with some floor oil such as linseed oil. This should be at once rubbed with sandpaper which removes all surplus oil and polishes the floor. After this an wax may be used according to its directions, and then after a whittled brush is used the old floors will be as slick as new ones. Floors. After this they should only be washed with ammonia.

### A Bill Providing for a New Patent Office

ON January 17th 1911 Mr. Buttky introduced a bill providing for the construction of a Patent Office of the United States. The sum of \$1,000,000 is to be appropriated out of any moneys in the Treasury not otherwise appropriated for the erection of a fireproof building. It is very doubtful if the bill will be taken up during the present session because of all families who present conditions in the Patent Office will recognize the necessity of the new building.

### Recent Improvements in Machine Tools—II

[I]t has often been said, and rightly so, that the perfection to which metal working has attained is one of the miracles of modern times. In many factories throughout the country the various pieces are turned, milled, sawed, planed or ground in such quantities at such speeds and with such unflinching accuracy as to command the admiration of the observer. Yet in spite of this perfection there always seems to be room for further improvement. This is the second of a series of brief articles on recent improvements that have been made in machine tools. [Editor.]

**I**n bevel gear cutting machines it has long been the custom to tilt the cutter carriage to the proper angular position desired.

The disadvantage of this proceeding has been that such a structure lacked the proper rigidity for heavy cutting—a disadvantage which has been particularly noticeable since the advent of high speed steel cutters. This lack of rigidity is due to the mounting of the reciprocating cutter carriage upon the rotatably adjustable slide and the eccentric route by which the motion is transmitted from the primary mover to the cutter spindle and feed screw.

A recent patent granted to W. F. Zimmerman of Newark, N. J., shows a marked commercial advance in the art of cutting bevel gears. Instead of tilting the cutter carriage, the patented procedure is to work table which is capable of being tilted to the proper angle. This table is so constructed that the strains imparted thereto by the cutter are taken by a base of rigid construction.

The advantages of this device are at once apparent. In the usual construction where the cutter is adjusted, there are three sliding surfaces necessary—two for the cutter and one for the work table. But by adjusting the work table, only two sliding surfaces are required—one for the cutter to reciprocate thereon and one for the work table. Then too a low cost adjusted drive necessary to rotate and feed the cutter is required. It also eliminates the additional means required to control the reciprocating movements of the cutter slide and the indexing of the blank the index drive being practically the same as usually found in ordinary spur gear cutting machines.

As seen in the figure, an adjustable slide 2 is provided with clamps 26, operated by handles 28 so that the slide 2 can be firmly secured to the frame 1. Hinged to one end of the slide 2 is a tilting bed 3 having rotatably mounted thereon a work table 4. A work arbor 6 is secured in this work table by means of a differential nut 5 and centers the bevel gear blank 7 depending from the center of the tilting bed 3. A sequential arm 9 having a worm wheel segment 10. This arm is secured to the slide 2 by means of a bolt 56, its outer periphery being rigidly clamped by means of a clamp 57 to a fluted portion within the aperture of slide 2, through which the arm passes.

The tilting bed 3 and the bevel gear blank 7 are adjusted to the proper angular position by the worm 11, rotatably mounted in the slide 2, engaging the worm wheel segment 10. On one end of the worm 11 is a helical gear 12, held in position by means of a nut 13 which engages with a helical gear 14. This gear 14 is slidably keyed upon and rotates with the adjusted segment adjusting shaft 15, and is held between the bearings 16 in the slide 2. The forward end of the segment adjusting shaft 15 projects beyond the frame and is provided with a graduated dial 17 and a square end 18 to receive a crank

In this bevel gear cutting machine, a distinct improvement has been effected in machine tools. Instead of tilting the cutter carriage, the patented procedure is to work table which is capable of being tilted to the proper angle.

handle. The ratio of the worm wheel segment 10 and worm wheel 11 and helical gears 12 and 14 is such that for each turn of the segment adjusting shaft 15, the bed 3 is adjusted one degree indicated by the dial 17 graduated to read in minutes.

As seen in Fig. 5, a graduated segment 18, reading in degrees, is secured to the bed 3 in connection with a vernier scale 21 resulting in tenths of a degree to indicate the exact angular position of the work at all times.

The work table 4 is rotatably mounted in the bed 3 and is provided with 7 slots 21, to secure the blank to the table. The index wheel 22, which rotates the work, is arranged upon the periphery of the work table 4. The work table 4 is supported near the outer periphery by a circular bearing 23, arranged in the bed 4, and is held thereby by a circular plate 24 secured to the bed 4. This plate 24 is provided with a circular groove to form a channel for the cuttings and the helical cut lead them into the base of the

main frame. The plate 24 also serves as a guard to protect the index wheel from chips and dust.

The index wheel 22 is rotated by an index worm 27, rotatably mounted in an adjustable bearing 28 on the bed 3. The bearing 28 is adjusted toward or away from the index wheel 22 by means of the handle 30. A stop-screw 31 is provided in the bearing 28 to gauge the depth of engagement of the worm 27 and wheel 22. A helical gear 32, engaging with a second helical gear 33, is mounted on one end of the index worm 27. The gear 33 is loosely mounted upon the biased shaft 34, passing through the lugs 35 and 36, and the lug 37 between the lugs 35 and 36 is supported by the ways of the main frame 1. The helical gear 34 is rotated by a helical gear 38 rotatably mounted in a bearing of the slide 2. This arrangement of helical gears provides for transmitting a rotary motion from the helical gear 38 to the index worm 27, independent of the angular position of the worm 27, and for the disengagement of the index worm 27 from the wheel 22 in all the angular positions of the worm 27.

The cutter carriage 48 with rotary cut-  
ter 49 is reciprocated vertically by well known means.

When the work has been adjusted to the proper angle, the slide 2 is adjusted longitudinally toward the cutter carriage 48 by means of the screw 46, the end of which is adapted to receive a crank handle. The amount of adjustment is indicated by the dial 50 graduated to read in thousandths of an inch. After the work is secured to the table, the end of the nut 6, the projecting end of the main drive 6 is supported by a triangular arm 51, slidably arranged upon two posts 52 and clamped thereto by means of the handle 53. The posts are slidably mounted in the bearings 54, provided in the bed 3, and are clamped to the bed 3 by means of the bolts 55.

(To be continued)

### The Oldfield Bill Cartooned

**T**HIS accompanying cartoon, reproduced by courtesy of Judge from the columns of that weekly, tells its own story. Read now of the SCIENTIFIC AMERICAN who have followed the attempt to pass a measure which cannot but have a destructive effect upon our patent system, and which must inevitably discourage invention will appreciate the graphic truth of the cartoon. Judge's title for the picture vividly inspired by a resolution addressed by the Inventors' Guild of New York city to President Taft, read:

Invention has contributed the greatest blessings of civilization and for America has laid the ground work of our wonderful industrial prosperity. The American patent law, by its liberality to inventors, has fostered the inventive faculty and made us the foremost inventive people. If we value future progress and continued prosperity, we should change our patent laws only after the most scientific and searching study, and only upon the most conclusive grounds.

**A Non-refillable Bottle.**—In patent No. 1,040,757, to Charles C. Pines, assignor of one half to Jacob W. Fine, both of Naticket, Pa., is shown a bottle in which there is provided a longitudinal passage parallel with the neck outlet and opposite said passage is another longitudinal passage communicating with it through a lateral opening and a second longitudinal passage contains a ball which controls communication with the interior of the bottle to prevent refilling and may be removed to permit the contents of the bottle to be dispensed.

By courtesy of Judge. Shall we now permit the Oldfield Bill to become a law and destroy this monument?

## Use the Broadway Limited Between New York and Chicago

It leaves Pennsylvania Station, in the heart of New York (one block from Broadway at 32d Street) at 2 45 P. M. to-day. Connecting electric train leaves Hudson Terminal (five minutes from Wall Street) at the same time. It arrives Chicago, Union Station, at 9.45 to-morrow morning.

It is all-steel, all-Pullman with parlor-smoking or club car, drawing-room sleeping cars, dining car, compartment cars, and observation car—all of the newest and brightest design and electric lighted. It has a library of best current literature, and the latest periodicals and newspapers, terminal telephones, a bath, barber, ladies' maid and manicurist, a stenographer, and a trained crew picked for their efficiency.

## It is The Time Saver de Luxe

It makes the over-night run at comparatively low speed over a rock-ballasted smooth-riding roadway which is the short line between New York and Chicago—the best guarantee of promptness and comfort. The dining car service is exceptionally high grade.

It represents Pennsylvania Railroad service in its very best form—a service that has been the standard of America for more than half a century.

It is the most convenient, comfortable, complete, and reliable service between New York and Chicago.

It leaves Chicago 12.40 P. M. to-day and arrives in the heart of New York at 9.40 A. M. to-morrow

## PENNSYLVANIA RAILROAD

### RECENTLY PATENTED INVENTIONS

These inventions are open to all persons. The active are awarded by special arrangement with the inventors. Turn on application to the Advertising Department of the Scientific American.

#### Particulating to Apparel.

**JOHN T. DUFFIN**—A. H. HANCOCK, care of Ralph R. (1100) 170 Broadway New York N. Y. The invention relates to improvements in hawks and particularly to belt buckles and has for an object the provision of an improved catch or latching structure adapted to be readily engaged and disengaged but firmly held in place when engaged.

**GARRETT W. KELPPE**—BOSWELL A. HANCOCK 22 W. 41st St. Manhattan N. Y. N. Y. This invention is more especially designed for stiffening the yokes of ladies dresses and waists, such as, one along the back and arranged for convenient location in the yoke and sufficiently pliable, to readily conform to the shape of the wearer, with a view to give the desired stiffness to the yoke without rendering the garment uncomfortable.

#### Of Interest to Farmers.

**JOHN J. LAMER** and **J. SIMMONS** (telephone No. 2) Havana Cuba. For the purpose of enabling an animal to more readily carry a load attached to a pole or line on the main shaft adapted to turn the shaft or to engage a vehicle a main bearing body mounted to swing on the main shaft in auxiliary bearings on the main bearing body and head being mounted to swing on the auxiliary bearing base.

#### Of General Interest.

**PENNA. FOUNT**—R. F. LARSEN, Brandon Minn. The invention provides a one-piece post which may be driven directly into the ground and which does not require tamping. This provides a post with means for holding the fence wires securely but in such a manner that they may be released from the post when desired.

**JOHN L. BUCHHEIT**—W. O. LAMAR, Nocton Va. This protector is formed of fixed and movable parts consisting of a plate and supporting frame. A wire of chain is supported in fixed position inclined, may be drawn to the vertical by means of a handle set in the ground and inclined in opposite directions, this upper end or handle being connected with the top or ridge line of the frame, the latter being placed over and parallel to the row of plants needing protection. Another portion of the protector is composed of a series of adjustable plates, and a third series may be employed and adapted to extend over the plants, or fully folded back for loading the plants. Mr. Lamer has invented another protector formed of two oblong plates connected by their distal ends to be made to rotate whereby the device is adapted to be applied over and protect plants and with means for supporting the protector when turned on its side so that it is held constantly in position for replacement over the plants.

**COMPOSITION OF MATTER TO BE USED AS A FLEXIBLE COATING**—P. M. H. HANCOCK, care of W. O. LAMAR, Nocton Va. This invention relates to a coating material to be used as a substitute for plastic films and other forms of water and acid proof coverings and linings. An object of the invention is to provide a flexible covering impervious to acids and alkalis, of a water proof and acid proof material for use as a roof covering or in any locality where it is desired.

**IMPROVING A FLIP**—J. F. WALLACE, Yonkers, N. Y. The invention provides a device whereby photographs may be developed in the daylight. The device is constructed so that the flip is effectively subjected to the developing fluid.

**FLEXIBLE BED**—J. C. MURPHY, Midway Pa. An object here is to provide a device which is more easily manipulated than the ordinary flexible bed in that it has greater leverage upon the flexible members. It costs no more than the ordinary bed and is adapted to be used in different operative positions when it is removed from the bed.

**LIFTER AND CARRIER FOR INVALID**—EDWARD J. GILMAN, Richmond Va. This invention relates more particularly to the construction of a bed on an auxiliary support adapted to be positioned upon the bed to receive the patient and means for moving the support in a plurality of directions and for raising it entirely from the bed to a point remote from the same the means serving to hold the support in different operative positions when it is removed from the bed.

**KEY CUP**—A. TAYLOR 10 P. 42nd St. New York N. Y. Among the principal objects which the present invention has in view are to provide means for preventing injury to articles by moisture while in storage or transportation and to provide a simple efficient and economical means for detaching the moisture from cartons or other such devices. This device may be used for holding tennis balls, cigars, candles, and a wide variety of other materials.

**DRINKING CUP**—C. A. BRADY, Pleasant N. J. This cup is made of paraffine paper in

### Tools with a Pedigree

The name Keen Kutter and the Keen Kutter trade mark are everywhere being recognized as standing for every physical perfection in tools—for steel that is perfect in texture, so exactly forged, shaped, tempered and hung as to do a maximum of labor with a minimum of effort and wear. These certain, guaranteed qualities have so long been characteristic of

## KEEN KUTTER Tools

that the line has become almost world-famous. Tool-wise mechanics no longer pass thumb along the edge of hatchet, draw knife or chisel to test its keenness, nor do they belt and swing a hammer or axe to learn its "hang."

They simply look for the trade mark and when they see it, buy. Yea, too, can be as sure of good tools as these men, if you follow their certain way of selecting. But, if by any chance a tool you buy, bearing our trade mark, should show a flaw or defect, your dealer is instructed to refund your money. That is the Keen Kutter guarantee.

"The Recognition of Quality Means Long Life. And the Price Is Forgotten."

—J. H. HANCOCK, Trade Mark Register.

If not at your dealer's, write us

Rumely Bulletin No. 11

## This Trademark Means Farm Efficiency

This Trademark is well known to the 6,400,000 American farmers. It has appeared in farm papers many millions of times in the past 60 years. This Trademark is now being placed on 51 Rumely Machines—Engines Tractors, Balers, Husker-Sheeters, Grain Separators, Cream Separators, Engine Gang Plows, Saw-Mills, Tank-Wagons, Corn Shellers, etc.

Every Rumely Machine *saves time—saves energy—saves money. EVERY RUMELY MACHINE HELPS TO LOWER THE COST OF LIVING.*

Fifteen factories are now working full blast to help supply the demand for Rumely Power Farming Machinery and 12,000 dealers are busy distributing these Rumely machines among the farmers.

The Rumely Business has grown to be one of the basic industries of the United States.

If you own a farm or are interested in farming, be a leader towards better methods and send for a Rumely Catalog and other information on power-farming.

Let Mr. Smith Tell How the Multigraph saves \$550 a Year on Letter-heads alone, and has Materially Increased His Business

Here's Mr. Smith's Own Statement in a Letter to Us:

"The Texas Gum Company started business in a very small way, and up to the time we installed our Multigraph we did not undertake any extensive advertising campaign, but since the installation of an American Printing Multigraph we have been enabled to carry on quite an active advertising campaign continually, which has been the means of a very material increase in our volume of business. We would under no consideration consider being without the use of the Multigraph in our office."

Our Multigraph cost amounts to \$550. It has enabled us to produce a large number of letterheads that we are now using. It has also enabled us to produce a large number of circulars and other literature that we are now using. It has also enabled us to produce a large number of business cards that we are now using. It has also enabled us to produce a large number of other literature that we are now using.

**MULTIGRAPH**  
Produces neat printing and form-keeping results.

Send me a card for the \$50 letter head sample you find in this Multigraph sample. I will send you a card for the \$50 letter head sample you find in this Multigraph sample. I will send you a card for the \$50 letter head sample you find in this Multigraph sample.

the form of the frame of a cone and is made of a single sheet of paper doubled up and having the sides connected with each other the bottom being flat and upon which fold are fastened in place by a separate strip thereof and overlapping the same.

**LOCKER**—J. NAGELAND, 275 FIFTH AVE., Brooklyn, N. Y. To provide a hinged form shaped to prevent buckling when the lock is made of light material; to provide a hinged construction shaped to the contour of the socket, to provide a frame for the socket having the glass and picture frame formed integrally therewith to form an interior assembly constructed from one portion of the frame to engage the other portion, such as the principal objects of Mr. Nageland's invention.

**CLIANUS LETTER SIGN**—W. RALPH ROBERTS, N. Y. The invention consists in securing between overlapping areas of opaque wire glass opaque letters assembled and arranged to form a reading sign the contrast between the opacity of the letters and the transparency of the glass imparting an aerial and unsupported appearance to the sign. A simple means is provided for hiding the overlaid glass on the transparent letters.

**SAFETY BOTTLE HOLDER**—T. ZANERKAR, care of M. A. MATTHEW, 120 Grand St., Brooklyn, N. Y. The holder is arranged to permit the salesman readily to place a bottle of medicine and prevent unauthorized persons from removing the bottle from the medicine store. The holder is provided with a slide cover which may readily be opened by the salesman but which is locked in closed position by the introduction of the bottle.

**DESK PAD**—R. OLSEN, care of K. BROOKLYN, N. Y. The invention relates to a desk pad and more particularly to a corner pad for desk pads or constructed in addition to performing its usual functions of guarding a corner of a sheet of blotting paper it may also be used as a receptacle for small cards and other articles.

**BRIAL VALVE**—J. BREMER, 2210 Metropolitan Ave., Middle Village, L. I., N. Y. The object of the present invention which relates to a previous patent No. 983,994 is to provide an improved valve arranged to accommodate one or a plurality of holders and to protect the latter from venous by providing horizontally seated cylindrical compartments, one for each body, these compartments being practically airtight and waterproof.

**COMBINED TANK AND MAP RACK**—R. W. HUNTER, 615 1/2 Street, Little Rock, Ark. The invention consists of a tank with a base supported under the table top. In the base is a rotating cylindrical casing provided with a number of rollers for accommodating any desired number of maps. The maps may be drawn out of the cylinder, and through a slit in the table top, and spread out upon the table.

**HOLDER HOLDER**—J. H. HAYES, care of H. HAYES, P. O. Box 1075 Butte Mont. The holder is made of resilient material with flanges at its ends for holding the holder against the body of the holder and with the central portion of the body formed in a spring loop which serves as a handle and also as means for holding the flanges rigidly in position.

**THIN**—J. T. HALL, Utica, N. Y. The aim is to provide a trim, arranged to permit in placing the pad upon any desired position securely holding it therein to prevent rotation of the body and to render the pad pliable and at the same time maintain the tension pressure on the affected part.

**STENT NIN**—J. SWANSON, 334 30th St., Brooklyn, N. Y. The principal object here is to provide a sign having means thereon whereby it may be secured in position on the side wall, the construction and arrangement being such that portions thereof are protected from injury by the wheels of passing vehicles.

**MAIL STRIPPER**—C. F. SMITH, 412 M. 10th St., Los Angeles, Cal. In this device different sized mails may be inserted, the mails automatically align themselves so that they may be withdrawn easily. This is obtained by positioning within a suitable casing an inclined hopper from which the mails are fed and a lever which when it may be readily withdrawn is assembled over.

**Hardware and Tools**  
**HANITON**—H. MONTAGUE, N. Y. The invention relates to a device for use as a clamp or as a spreader and stretcher for coil springs or as a valve lifter. It consists of a body of metal having a handle, one end and the other movable upon the rod, a fixed and a pivot mechanism being provided for this purpose.

**TELESCOPING POCKET RUL**—P. C. GREENHART, 1325 Union St. (rear) Dover, Ohio. This telescoping pocket rule is of light construction and arranged to hold open and yet may be extended to a length of 12 inches. It is provided with a number of telescoping sections provided with enlarged rear portions having sliding engagement with the following sections and having a contracted front and the enlarged rear of a preceding section to assist in the telescoping action.

## PATENT ATTORNEYS

## PATENTS

If you have an invention which you wish to patent you can write fully and freely to Munroe & Co. for a free book on the subject of patenting your invention. Please send address or a model of your invention and a description of the device, and we will send you a free book.

All communications are strictly confidential. Our vast practice, extending over a period of more than sixty years, enables us to supply means to obtain in regard to patenting your invention any assistance to the client. Our Hand Book on Patents is sent free on request. This explains our methods, terms, etc., and is sent to PATENTS, TRADE MARKS FOREIGN PATENTS, etc.

All patents secured through us are described without cost to the patentee in the SCIENTIFIC AMERICAN.

is an improvement in the type comprising a fixed jaw and a movable or sliding jaw, the latter being formed integral with the shaft which slides in the handle and is provided with a screw thread to which a portion of the handle constructed as a nut is applied for the purpose of adjusting the movable jaw. The fixed jaw has an inwardly inclined face and the adjustable jaw is formed with a V shaped toothed lifting surface.

#### Housing and Lighting.

**GAS CONSERVATION.**—M. DUBOIS, 40 Rue de Valenciennes, Paris, France. In the present patent the invention has reference to improvements in gas generators and has for its object the provision of a gas generator the use of which is so supplemented as to keep the approach of the burner completely clear.

**FLUID CLEANER.**—C. C. PARSON, Eldora, Iowa. This invention relates to cleaners for freeing the flow of boilers and other apparatus from accumulations of mud, scale and the like and has reference more particularly to a cleaner which comprises an elongated flexible body having an adjustable scraper mounted thereon.

**PORTABLE REMOVING CLOSET AND BATHING DISPOSITON.**—M. PERRY, care of Am Foundry & Furnace Co., Mounting 131. This apparatus is more especially designed for use in camps and other places having no sewer, and arranged to incinerate excreta and to evaporate urine etc. and to destroy garbage and other waste material and to utilize the same material as fuel for incinerating purposes.

**OIL BURNER.**—J. J. LARSON, Johnston, R. C. The principal object of the present invention is to provide a device by means of which oil such as kerosene may be vaporized and burned in a combustion state. A further object of the invention is to provide a simple form of burner to be used in cooking and heating stoves, which is made up of pipe, elbows, T's, etc., of standard size and quality.

#### Household Utilities.

**DUMB WHEEL HUIER.**—W. P. EISE, 40 Huguenot Place New Brighton, N. Y., N. Y. This guide is used entirely of metal so as to comply with municipal ordinances relative to the exclusion of combustible materials from elevator or dumb waiter shafts. Means are provided for securing the guides to the walls of the shaft, whereby the guides may be easily adjusted to make them adapted for different constructions of elevator cars and made of installation than those now in common use.

**Machine and Mechanical Devices.**  
**PISTON COMBING MACHINE OR CARDING KNIFE.**—P. F. POWER, 40 Rue de la Chapelle, Paris, France. This invention relates to improvements in automatic carding machines for a wool-carding engine in which the wool is carded, being placed in a trough is acted by a toothed drum rotating in said trough and afterward covered by a rotating brush or a saw toothed comb having an oscillating motion tangent to the drum and acting alternately.

**SPRIT THINER.**—J. R. BROWN, Danville Pa. This particular machine is adapted for drying oranges, grapefruit and the like subsequent to the operation of washing them. In the machine small streams of air are forced directly upon the fruit which is rotated so as to bring all parts into direct contact with the moving streams of air.

**SPINNING MACHINE.**—P. Z. BOOR and J. A. PARRIS, care of L. L. Deane & Co., New York City. The present invention is an improvement on patent No. 902,028. Its object is to provide an automatic spinning machine arranged to insure positive movement on the leading screw to cause the time to be the same and thus produce accurate winding of the fiber.

**TAPPING MACHINE.**—M. J. FORD 130 10th St. Newark, Pa. The machine provides a means for quickly forcing a tap into a tree and as quickly unscrewing it. It consists of a casing provided with a rotating handle, which is a step-down gearing connecting a motor with the handle that receives the tapping tool in which the tap is mounted. The motor is preferably of the pneumatic type.

**MILL.**—I. C. LAMON and M. C. LAYTON, care of Landon Mill Works, York Pa. The purpose here is to provide a mill in which the material entering the mill is caught by an upper rotating casing, the material being swept by the blade on the upper, and being forced by the angle into a revolution formed by a disk and the casing of the mill, where the rotation of the material is retarded by radial screw, while the blades of the screw act on the millings to break it up, so that it may be blown through bolting cloth.

**OPERATING MECHANISM FOR FLUID DRIVE.**—O. E. EMMETT and O. R. EMMETT, care of Evers & Son, 215 1/2 Market St., San Antonio, Texas. This invention relates more particularly to the combination of an operating member adapted to be operatively associated with a fluid drive and with water elements and the like, an operating member being in addition a screw) positive and adapted to be actuated by a screw shaft and a dog handle, the said dog handle being adapted to be actuated by a screw handle.

**PNEUMATIC ACTION.**—A. ALVER 500 E. 3rd St. Manhattan, N. Y. The invention pertains to piano players, player pianos and the instruments having pneumatic, and the object is to provide pneumatic action which is exceedingly sensitive and insure a quiet striking and relling of the pneumatic and thus allows sounding of the same note in quick succession.

**GATE CONTROLLING MEANS.**—A. F. BAKER, 532 Brinker Ave. Atlantic City. This invention provides for automatically holding the gate when the cage has been brought to the proper position at a landing, automatically holding the gate open as long as the cage remains in the predetermined position and for automatically releasing the gate and causing it to close when the cage is moved above or below the landing or other predetermined point.

**LOGGING JACK.**—C. D. MOORE, Kirkland, Wash. In this Jack a ratchet is raised by means of a pivoted lever provided with a pawl adapted to engage a rotatable ratchet connected with the said ratchet bar through the medium of a piston. The action of the lever is to amplify the contraction, reduce the cost, lower the friction, and increase power, speed and efficiency of the Jack.

**DOWN PRINTING DEVICE.**—W. JACKSON, care of The Boston Times Co., 3rd Ave. & 30th St. Brooklyn, N. Y. In this invention use is made of an impression cylinder and a crown printing roll mounted to rotate in unison with the said cylinder and having peripheral bodies mounted forward from the peripheral face of the impression cylinder to provide the wall of the printing roll around the said cylinder with crown imprints at desired intervals.

#### Hallways and Their Accessories.

**CAR DOOR.**—H. WATERS, 417 Morrison St. Warren Pa. The principal object here is to provide a door embodying means whereby the door when in closed position will lie flush with the side of the cars, means being provided for opening the door by means of a handle, suitable rail being provided whereby the door may be rolled to uncover the opening the door moving into a position remote from the side of the door.

#### Pertaining to Vehicles.

**BUGGY SHAFT SUPPORT.**—B. M. PANDOR, Franklin Ky. An attachment for buggies is provided which adapts to support shafts or thills in raised position when the vehicle is not in use. The device consists of a spring actuated hook fixed to the longer front and adapted to engage with the cross bar on the shaft.

**BRACK MOUNTING FOR AUTOMOBILES.**—H. M. FERRY, Manhattan New York. This invention provides separate and independent brackets for the front driving wheels of the automobile so that either wheel may be locked when it is desired to prevent its slipping in the mud and the propulsive effect of the motor being in such case applied to the other wheel riding on dry ground.

**TIKK K ABROUHER.**—W. H. BELL, 274 W. 10th St. Manhattan, N. Y. N. Y. This value provides means for checking the free up-and-down of the carrying springs of a vehicle when such springs by the irregularities of the road, provide for simplifying and avoiding the construction and providing an alternative shaped to vary the operation in accordance with the degree of vibration.

**VEHICLE TIRE.**—H. L. HENNA, care of SCHWARTZ, 208 E. 10th St. N. Y. N. Y. This invention relates to vehicle tires such as shown in Letters Patent No. 751,948 formerly issued to H. L. Henna. The present invention provides a tire for wheels of automobiles and other vehicles and arranged to provide a self-cleaning surface and the use of an inflated tire tube, to render the tire puncture-proof and to permit of quick making repairs when necessary.

**Notes.**—Copies of any of these patents will be furnished by the **SCIENTIFIC AMERICAN** for a fee of six cents. Please state the name of the patentee, title of the invention, and date of this paper.

We wish to call attention to the fact that there is a position to receive copyright notices in every branch of patent or trade-mark work. Our staff is composed of mechanical, electrical and chemical experts, thoroughly trained to prepare and prosecute all patent applications, irrespective of the complex nature of the subject matter involved, or of the specialized, technical, or scientific knowledge required therefor.

We are prepared to render opinions as to validity or infringement of patents, or to render to clients advice in trade-mark and other connection matters.

We also have associates throughout the world, who assist in the protection of patents and trade-mark applications filed in all countries foreign to the United States.

## not to rim-cut.

# GENUINE

# DUNLOP STRAIGHT SIDE TIRES

Tire experts have long foreseen that the day would come when the Genuene Dunlop would be universally recognized as the ideal type of motor car tire. Present sales indicate that this time has arrived.

The Dunlop tire possesses every point of advantage to be found in any other tire ever used, and in addition has exclusive advantages to be found in no other tire.

In case of application, in protection against rim cutting, in strength and durability—the Dunlop is in a class by itself among tires—as one prominent manufacturer put it: The more you familiarize yourself with other tires, the more sure you are to use the Dunlop!

But remember, the Genuene Dunlop straight side Tire is made only by the

### Simply Explained

176 Pages, 156 Illustrations By ALFRED P. MORGAN Price \$1.00 Postpaid

*The simplest, latest and most comprehensive popular work published on wireless, for the wireless operator, student or professional.*

This undoubtedly one of the most comprehensive treatises on the subject, and a clear study of its pages will enable one to master all the details of the wireless transmission of messages. The author has fitted a long list of matter and has succeeded in furnishing a brief, comprehensible explanation in simple language of the theory and practice of wireless telegraphy and telephony.

The book treats the subject from an entirely new standpoint. It is well illustrated by over one hundred original photographs and drawings. All diagrams have been made in perspective showing the instruments as they actually appear in practice. The drawings are carefully labeled and labeled. Many of the photographs are accompanied by photos showing how the same and purpose of each part.

*A book the wireless apparatus operator cannot afford to be without. If available one should order it immediately. Also available in the German.*

## Always on Guard

No matter where a ship may be along the American coast no matter how dark, or cold, or stormy the night, the coast guard is on watch patrolling the nearest beach or rocky cliffs.

This man, always on guard, could, by his own unsupported efforts, do little to save life, or to guide ships away from perilous points.

As a unit in an efficient system and able, at a moment's notice, to command the service of his nearby station, he becomes a power to whom all ship owners and passengers are indebted.

In the same way, the Bell Telephone in your home and office is always on guard.

By itself, it is only an ingenious instrument, but as a vital unit in the Bell System, which links together seven million other telephones in all parts of this country, that single telephone instrument becomes a power to help you at any moment of any hour, day or night.

It costs unwearied effort and millions of dollars to keep the Bell System always on guard, but this is the only kind of service that can adequately take care of the social and commercial needs of all the people of a Nation.

## Build a Boat

This Spring and Double  
Next Summer's Sport!

You will never lose the full joy of boating until it is your own. Your creation that fits and dips and skims along the water you get out place as if materials. Everyone who has built a Brooks Boat wants to build another for the sport of boating. Also for the satisfaction and confidence given by knowing what a under you—that every bit is staunch and true. And you get the most to a fraction of regular price.

The Brooks System Makes It Easy To Build  
A Motor Boat, Sail Boat, Row Boat or Canoe

Not only easy to construct but easy to pay for. We used all parts of frame complete, ready to put together. Plans and materials on clear and simple systems without the least expenditure in time or money. Every part, every tool, every material in place. Satisfaction guaranteed or money refunded. You can build any style boat you want from our well known patterns, complete from \$200 to \$1200 according to design selected. Brooks Boat Works, Inc.,—Largest boat factory in the world, has been building boats for over 40 years. You will find the boat factory that makes boats for you on an obligation. Write for more. Address: Brooks Boat Works, Inc., 2522 Midway St., Sandusky, Michigan, U.S.A.

which was held last month in Paris when it was arranged that such of the big clubs in the organization representing France Great Britain, America Germany Belgium Italy Sweden Denmark America Holland Hungary Russia Switzerland Roumania and Egypt, should subscribe its portion to a general fund which shall constitute the prize. A special organization committee already has been named to go ahead with the work. Baron de Kuylen de Nyevelt is chairman and makes his headquarters at the offices of the International Association of Recreational Automobile Clubs in Paris.

As regards the contest itself, the restrictions are very simple. The fuel must be suitable for existing internal combustion engines. It must be less expensive of course. It must be readily procurable. It must be of such nature that it cannot be captured by trams national or international. That is all. The formal announcement of the conditions in detail which are now in course of preparation in the hands of the committee and which in sum and substance will be as given above assurance will be obtained from the various governments that the new fuel will be untaxed at least that it will be taxed only very moderately.

### A Comparison Microscope

(Continued from page 11)

A highly advantageous is to be able to compare directly under the microscope a specimen of the suspected article with a specimen of the same material of an unquestioned quality. In many of the investigations in botany and mineralogy bacteriology and especially in medicine the comparison microscope would prove equally valuable. In the instrument of this character which can be adjusted to show two objects in the two halves of its field of view is thus treated in the accompanying photograph. It consists essentially of two microscopes objectives optically connected with a single eyepiece by means of a flat total reflector prism. The two placed under the eyepiece and one at the top of each objective tube.

The prism is at the top of the eyepiece and the micrometer screw is at the top of the focusing of the microscopes any difference in the thickness of the objects or the refractive index compensated by means of the screws (F).

The two prisms beneath the eye pieces are mounted in a slider which can be moved to right or left by turning the plunger D so that the field of view can be occupied entirely by either of the microscopes or by divided equally between the two. The median position of the prisms is marked and maintained.

The instrument therefore is virtually equivalent to two microscopes of the ordinary type but it possesses the additional and important advantage that the two objects under observation can easily and suddenly be brought into the same field of view for close comparison.

This comparison microscope which is protected by a German patent is mounted on a hinged stand so that it can be used in a vertical or inclined position and it can be fitted with every accessory of the most elaborate microscope.

### The Current Supplement

IN the current issue No. 1507 of our publication W. B. Rossiter concludes his article on Alloys Suitable for Instrument Work. Dr. J. B. Temple writes on Wood Waste Utilization—how extensive river improvements on the Missouri in which concrete piles have been used are described in an illustrated article—John Deere reports on the campaign against fire which the city of Cleveland has been waging with much determination—Maurice Ellis and Dray describe a system whereby oil can be used in the ordinary type of gas engine—Prof. Eugene writes on the Significance of Spectroscopy for the Atomic Theory—Prof. F. J. Cole describes a remarkably simple method of photographing sound waves.

## The First Aid for Better Business

*The Willys ¾ Ton Utility Truck—\$1250*

(Chassis & Only)

**A**LL over America there are thousands of concerns that could further develop their business by simply adding some modern equipment. Take one item alone—and a very costly one, too—the hauling of merchandise. One Willys Utility truck will enable you to extend your delivery operations 100—200—300, and in some cases, even 400%—depending, of course, upon your local conditions—with *no additional help.*

The very best work the very best single horse can do is eight to ten miles each way per day. The Willys Utility truck can do 30 to 40 miles each way per day and then work all night if necessary. Which figured from another angle means that one of these trucks can do five to six times as much practical delivery work as any six horses you own.

This truck can accomplish more than any other of equal power and capacity and costs you considerably less.

This is the most practical small truck ever built. It is not a built over or revised pleasure car chassis—it is a practical truck built along practical truck lines by practical truck builders

in one of the largest and foremost exclusive truck plants in America. We build nothing but trucks and have been building them successfully for over ten years.

Note the following practical truck specifications:

The powerful 4 cylinder motor is controlled by our patented governor. It cannot be driven over 18 miles an hour. It has quick demountable solid tires 36 x 3 front and 36 x 3½ rear. It has an unusually rugged pressed steel frame doubly reinforced at points where it will receive the greatest strains. The wheel base is 120 inches.

For further particulars see the nearest Gramm dealer or write us direct.

*Literature on request Please address Dept. 6*

## Science

**A Remarkable Photograph of a Meteor Trail** is published in the *Bulletin of the Astronomical Society of Boston*, having been previously published in *India*, where the original was, on account of its unique character, awarded the first prize in a photographic competition held by the *Times of India Illustrated Weekly*. It was taken by an English aviator, A. Hemstedt at Mhow in India. The meteor, which was very brilliant, was visible for about 2 seconds in its passage across the sky, but its trail persisted for 20 minutes. The photograph taken 15 minutes after the passage of the meteor shows the trail as a very irregular sinuous line—the result of drifting in the wind.

**Long-range Weather Forecasting**, so long discredited by scientific men, appears to be gaining respectability. Little by little, with the progress of meteorology. The last annual report of the Dutch East Indian meteorological service mentions the fact that forecasts of the strength and weather characteristics of the easterly monsoon are issued at Batavia each April. Official monsoon forecasts have been regularly made in British India for many years. In the United States Weather Bureau, Sunday forecasts for a week in advance have become an established institution. Of course in all these cases the forecast deals with only the broader features of the weather over wide areas.

**Cataloguing American Doctoral Dissertations.**—The Library of Congress has undertaken the important task of preparing an annual catalogue of the printed doctoral dissertations submitted to the Library of Congress by the United States, exclusive of those submitted for professional degrees. This is a class of literature which librarians and bibliographers find particularly elusive, so that the new publication will fill a long-felt want. Through the operation of the International Union of the Library of Congress hopes to acquire copies of all doctoral dissertations heretofore printed in this country, and to print catalogue cards for them. Eventually an attempt will be made to compile a list of the dissertations published before the beginning of the annual publication.

**Weather Reports from Arctic Canada.**—At the last meeting of the International Polar Commission, the Telegraph, Director Rupert, of the Canadian meteorological service, announced that the Canadian government would shortly be asked, through the Royal Society of Canada, to establish wireless stations at several far northern points, such as York Factory, Fort Chipewyan, Fort Simpson, and in Hudson's Bay. If this is done, arrangements will be made to have daily weather reports forwarded from these places. This would mean a very notable extension of the weather maps of Canada and the United States. Mr. Rupert also announced that his service is now making a daily synoptic weather chart of the northern hemisphere, similar to that prepared in Washington, and that its value in forecasting has exceeded his most sanguine expectations.

**Temperatures in the Antarctic.**—Some of the meteorological results of Amundsen's antarctic expedition are discussed by Dr. Haas in the *Monatsschrift der Schweiz. Anstalt für Wetterkunde*. Continuous observations were made at Framheim during the ten months, April, 1911, to January, 1912, inclusive. From these, by comparison with previous records in the antarctic, values for February and March can be computed. On these days the mean temperature of the station for a year is found to have been  $-25.2$  deg. Cent. ( $-13.4$  deg. Fahr.), which is the lowest yearly temperature heretofore observed at any place on the globe. The lowest individual temperature observed was  $-58.5$  deg. Cent. ( $-73.3$  deg. Fahr.). Much lower temperatures than this have been observed in the "cold poles" of Siberia.

**The Remarkable Humidity of the Atmosphere** that began in June, 1912, and persisted at least well into the autumn, continues to be the subject of numerous reports from widely scattered points in the northern hemisphere. Dr. A. de Quervain, the leader of the Swiss expedition that crossed Greenland last summer, states that blue skies prevailed on the west coast early in June, before the early summer. During the latter part of June, June 10th to August 1st, the members of the expedition were struck by the gray, leaden appearance of the sky, in the absence of clouds, and even when the explorers were travelling at altitudes above 8,000 feet. The Eskimo of the east coast described the phenomenon as a phenomenon, which they believed to be an omen that the following year would have no summer. A report from Zurich states that the haze seemed to be noticeable at the Swiss observatories about October 11th. Dr. Mäurer, president of the International Commission for the study of the beginning of the haze with the eruption of Katmai volcano, in Alaska, seems to leave little doubt as to the nature of the phenomenon.

## Automobile

**Heaviest Military Motor Track.**—The heaviest motor vehicle which has fulfilled all the regulations of the War Department in connection with the subsidy arrangement is the Avanti-trailor, built by the Avanti company with the trailer has a carrying capacity of 30 tons.

**Automobile Brakes that Operate a Signal.**—Charles F. Marston of Great Neck, N. Y., in a patent, No. 1,049,740, provides a signal device which is connected with the brake mechanism so that the signal is operated when the brake mechanism is manipulated. In other words, so that an automobile approaching another from the rear will be warned when the automobile in advance applies its brakes to reduce its speed or stop, thus preventing rear end collisions.

**Germany Has 828 Subsidized Road Trains.** According to figures which have just been issued by the German government 120 motor "road trains" have been subsidized for the year 1913 by the kingdom of Prussia, and 15 by Bavaria. This number added to the 600 which were under the control of the government in 1912, there are now 828 of these motor trains at the disposal of the German military authorities in case of war.

**Next Paris Salon in October.**—In view of the fact that hereafter the Olympia Automobile Show at London has been held a few weeks before the Paris salon, the organizers of the latter have decided to postpone to a degree so as to make the French exhibit a mere "appendix" to the British show. To counteract the impression and to recapture for France its former high place in the automobile field it has been decided to hold the next Paris automobile exposition in October, instead of November, so as to antedate the Olympia exhibit.

**Accident Statistics for Motor-car Miles.**—Someone with a predilection for statistics has figured out that in Great Britain alone about 1,000,000,000 miles are covered annually by all series of vehicles including motor cars. During the past year 770 persons were killed by vehicle traffic, that is to say, one person for every 2,133,333 miles. Motor vehicles to the number of 20,000 covered approximately 300,000,000 miles and killed 200 people, or one person for every 1,500,000 miles.

**An Automobile for Fording Rivers.**—In order to meet with the rigid requirements of some of the British colonies in respect to motor cars which can be taken any where and everywhere, an English manufacturer has invented a motor car which can be driven through water four and even five feet deep. All electric condenser magnets and batteries are protected by special insulations and extra lengths of pipe are attached to the exhaust pipes and to the intake manifold. When a car of this type is driven through five feet of water the top of the radiator and the seats show above the surface.

**A Daimler Lubricating System.**—Patent No. 1,050,108 to the firm of Daimler Motorenwerke AG of Stuttgart, Germany, the associate of Paul Daimler and Albert Höpfer of Cannstadt, Germany, shows a lubricating system which has a number of pumps for supplying lubricant to a number of corresponding parts to be lubricated, the pump cylinders being connected in series and to the parts to be lubricated with each cylinder having an oil inlet port and a piston reciprocated in each cylinder and over-running the inlet port, so that each piston will operate to supply oil to the next succeeding cylinder on the compression stroke of each piston.

**Improvements in Carburetors.**—It is a pretty well known fact that the action of many of the carburetors at present on the market is not all it might be from the point of efficiency and flexibility. In this respect it is interesting to note that a number of car manufacturers have observed a material improvement in the efficiency of the simple expedient of fitting an auxiliary air valve controlled by the operator. To the person who takes an active interest in his car and its running the increase in efficiency and flexibility which in many instances can be obtained with this device is a material consideration. It will more than offset the necessity for attention to its proper setting according to the demands of the motor.

**New Use for Postal Automobiles.**—The Bavarian government has found a new use for the many automobiles employed by the Post Office Department by means of which the danger of great conflagration in the rural districts is minimized. If a bug fire breaks out in any of the villages farther than ten miles from a city, the fire engine of the nearest city are attracted to the automobile and hauled at high speed to the scene of danger. As only the larger cities have motor fire departments, the assistance of the postal motor cars is invaluable to the surrounding villages. The first practical test of the plan was made last month in Bamberg. The village situated about the city for many miles was reached in less than 20 minutes. The car, which was hauled to the scene of the automobile, the run was made in 24 minutes, and the assistance rendered by this engine was of great value in extinguishing the fire.

## Aeronautics

**A Proposed Aviation Field at College Park, Maryland.**

—On January 14th Mr. Gallinger introduced in the Senate of the United States a bill to authorize the Secretary of War to acquire the machine shop now owned by the United States for aviation purposes at College Park, Maryland, for aviation maneuvers and other military purposes. The sum of \$400,000 is asked to carry out the provisions of the bill.

**An Alexander Graham Bell Flying Machine Patent.**—In patent No. 1,040,001, Dr. Bell, instead of making the support of the body of the machine rest on the wheels at their lateral marginal portions and flexing or warping those portions to preserve or restore the balance of the machine makes such supporting surfaces rigid and non-flexible and employs a vertical balancing rudder which, when the machine is in normal horizontal position, lies approximately in the medial vertical fore and aft plane of the machine. This rudder is mounted on an upright axis, and when the balance of the machine is disturbed, the rudder is by suitable means turned about its axis to incline it to that side of the axis toward the lower side of the machine, the resistance offered by the air as the machine moves rapidly forward, operating to again restore the balance of the machine when the rudder is inclined in the opposite position. The axis of the rudder is preferably located approximately at the center of pressure of the air acting to support the machine. For operating the balancing rudder, an arm projects from its upright shaft and has a fork which engages the body of the rudder. As the balance of the machine is disturbed, naturally incline its body toward the upper or higher side, thus turning the rudder to the lower side of the machine for the purpose before described.

**Recommendations of the Chief Signal Officer of the United States Army.**—In his annual report to the Secretary of War Brig. Gen. James Allen, Chief Signal Officer of the Army invites attention to the recommendations made in previous reports concerning the urgent need of legislation to increase the efficiency of the Signal Corps of the Army. During the past few years the great development in radio-telegraphy, aviation, and in the organization of field signal companies has so greatly increased the duties devolving on the Signal Corps that the present organization is unequal to the task. In his annual report of the Corps. He asks an appropriation of \$3,000,000 to be distributed as follows: One million dollars for increasing the present equipment of aeroplanes, hydro-aeroplanes and other aircraft for the purpose of warfare and for the purpose of training; one million dollars to be spent for one hundred aeroplanes, two hundred thousand dollars to be spent for maintenance, including spares, spare parts, gasoline oil, etc., two hundred thousand dollars to be spent for aerostats, including hydrogen, helium, and other gases; and one million dollars to be spent for the establishment of training schools known as centers of aviation, on the Atlantic, Pacific and Gulf coasts, on the Great Lakes and some central interior point, and a number of auxiliary centers as they may be possible to organize with a view to having a school of instruction in each State for the purpose of training officers of the regular army and the organized militia as aviators.

**Curtiss Awarded Collier Trophy for 1912 and 1913.**—(Then H. Curtiss, flying motor boat, the largest motor boat in America, and the creation which is said to have made aviation a war machine than either automobilism or heating has won him the distinction for the second time, of receiving the Collier Trophy awarded annually for the greatest achievement in aviation.) He actually flew a distance in excess of a mile in the old "June Bug". In 1909 almost exactly one year later, Curtiss won the NEPTUNE Aeronautics Trophy for the second time at Long Island Sound. He flew 24 miles or nineteen circuits of a circular course. His famous flight from Albany to New York the longest flight of the year, won him the trophy in 1910 for the third consecutive time making him its holder in perpetuity. In 1911 the new trophy, to be awarded to the most signal aviator in aviation each year was offered by Robert J. Collier then president of the Aero Club of America. It was awarded to Curtiss that year for the invention and demonstration of the single pontoon hydro-aeroplane, the first machine to successfully rise from and alight on the water. There is no record of a single serious accident to the operator of a hydro-aeroplane in America, though one machine and its operators were lost at sea in attempting to fly in a home-built hydro-aeroplane of upward of 400 miles, from San Pedro to San Francisco, starting in a fog following a three days' storm. The hydro-aeroplane piloted by Curtiss has been adopted by almost every navy of the world's powers.

### Motoring on Ice

IF by putting stanks on his feet a man can outstrip a horse, if by putting runners on a sailboat it can be made to race an express train why should not an automobile if mounted on runners develop a speed that would satisfy the craving of the most voracious of speed maniacs? The lack is not perfect. Nevertheless an automobile has actually been mounted on runners and has attained remarkably high speeds. The experiment we refer to was made by the Waterworks of the New York City. It stripped the car of all superfluous weight and mounted the chassis upon two pairs of runners. The car wheels were left upon their axles, but the tires were removed and in their place were fitted three sets of wheels. The rear pair in took most of the weight of the wheels, and by permitting the teeth to dig into the level and snow and propel the machine. With this novel craft Mr. Waters had great sport traveling over the broad stretches of the Kingsbury River.

It was not long without rival, however. Mr. Phillips Green, also of the New York City, came out with a smaller craft built for the fashion of an iceboat, but provided with a motor in place of a sail. The motor was equipped with an airplane propeller. A true-looking propeller it was, too, and it was driven by a 12 horse-power 2-cylinder motor. The automobile mounted on the other hand, was equipped with a 10 horse-power air-cooled motor. A race was arranged between the two sleds and the airplane craft easily showed its superiority over the automobile. One of our illustrations shows the two machines just after the race. However, the automobile was more powerful when it came to traveling through snow and it was used to drive a snow plow to clear the ice, as pictured in one of the photographs.

One of the speediest of motor iceboats is the "Go-devil," built for the U. S. Navy after the design of C. I. Davis. It is fitted with a 40 horse-power, four-cylinder twelve-cylinder motor, water-cooled, and an airplane propeller designed to drive the machine at 140 miles per hour. The propeller is placed in front of the boat and the steering rudder at the rear. When this machine was tried out last year at Ironsides Bay, Lake Ontario, it developed such speed as to astonish the spectators. A reporter who was present was positive that the machine had made 140 miles per hour on the seven mile stretch of good ice, and this story appeared in the New York daily papers. As a matter of fact the machine was not traveling at its highest speed, but was partly throttled down. The operator of the machine conservatively estimated the speed at about seventy miles an hour with the wind at his back and he did not feel inclined to let the machine travel any faster on her trial trip at least. Unfortunately, the good ice did not last long, and the next trial had to be made on snow, covered sheet. The snow was five inches deep. But even with this heavy handicap a speed of 40 miles per hour was easily obtained. The accompanying photograph of the "Go-devil" plowing through the snow at this speed shows how much of its energy was wasted in throwing the snow rather than propelling the machine forward.

Motor iceboating is in its infancy but it is one of the most fascinating and exhilarating of winter sports, and its development in the past few years offers alluring promises for the future.

### Astronomical "Balls"

THE *Balls* of the Astronomical Society of France others known as *L'astronomie* has for some time been publishing from month to month, delightful specimens of popular literature, the elementary facts of astronomy, some of which have already been mentioned in our columns. The following are recent additions to the collection. An astronomer happened to remark that he had taken some photographs of the moon through his telescope, whereupon he was asked whether he took them by flashlight. A member of the French Academy, M. Henri Bataillon in his novel "Les Nocturnes" the book which is laid in Venice, makes a pleasant look up his estate (Chinese one summer night, and so, in the zenith, the light of Orion.

### The Waterwheels of Hama

HAMA, in northern Syria, is justly famous for its huge waterwheels. The city lies some 110 miles northwest of Damascus on the banks of the river Orontes. It is undoubtedly a very ancient town, and is referred to in the Bible as Hamath the Great.

The river flows through the city in the form of an S, and upon its banks are four huge waterwheels, each bearing a name of its own. They are used for pumping up the water of the Orontes for irrigation purposes, and also for supplying the town.

The wheels are driven by the flow of the river on what is known as the undershot principle, that is to say the wheel is moved by water passing beneath it.

Automobile sleigh and motor iceboat just after a race which the latter won.

Twelve horse power propeller-driven iceboat

Automobile sleigh clearing the ice with a snow-plow

The "Go-devil" plowing through five inches of snow

The largest wheel has a diameter of about 70 feet, and the Syrians declare it is the largest in existence. Like the others, it is built of wood, a dark mahogany. The axle is of iron. The crowing of the wheels is incessant day and night. They never stop. In winter and during early spring the flow of the stream is partially blocked to reduce the rapidity of the revolutions, but on no account are the wheels actually stopped.

Placed upon the banks of the stream amid the trees and gardens for which Hama is justly proud, the wheels present a decidedly picturesque effect. They are the favorite rendezvous of the boys of the town. For

a few cents some of the more daring will climb up the spokes of the moving wheel to the summit and then jump into the stream below him.

### Fortunes in Foxes

THE phenomenal expansion of the black fox industry in the province of Prince Edward Island, Canada, has been made the subject of an elaborate report by the American consul at Charlottetown. That province is, it appears, the greatest center for fox farming in the world, thanks to the possession of a climate and soil that ensure an ideal weight, texture, and color to the skins. More than 80 per cent of all the captive foxes in Canada are kept on Prince Edward Island.

Black foxes (which include the silver foxes) furnish a skin which is not only extremely valuable, but is in such constant demand that its value has become almost as fully standardized as that of the diamond among precious stones, and does not necessarily fluctuate with the supply. These skins frequently fetch from \$1,000 to \$3,000 on the London market, the recent prices up-to-date being somewhere between \$2,500 to \$3,000. Aside from the industry in skins there has grown up an immense business in live animals for breeding purposes. It is stated that during the past summer \$10,000 a pair was not an unusual price, as compared with \$4,000 a pair for animals of the same quality in 1910. Prices of \$12,000 to \$15,000 a pair are paid for animals that have shown unusual fertility and it is rumored that a 2-year-old pair recently sold for \$30,000. One of the pioneer ranchmen claims to have refused an offer of \$50,000 for his establishment, coupled with a salary offer for his own services to run it. Fourteen companies for fox ranching have been incorporated in the island, and capital from the United States is beginning to be invested in these concerns. There are now about 50 large ranches stocked with purebred animals, while the number of places where from one to four or five pairs of some variety of foxes are kept is probably more than 300.

All the foxes on Prince Edward Island are now in captivity, the last wild fox having been killed early in 1911. It is claimed that the valuable strains have been improved in domestication. The animals are kept in pens or paddocks about 30 by 40 feet, surrounded by a large outer enclosure sometimes covering an acre or more. The fences are of 10 or 14 gauge wire, which is now specially woven for the industry. They are 9 or 10 feet high, with an overhead wire which exerts a pressure inward, and are sunk 2 or 3 feet in the ground. The kennels or fox houses are inside each paddock, or immediately outside, but opening into it. The mouth of the kennel is a crooked tube or spout, often built to imitate the entrance to a natural burrow.

The diet of the animals is extremely varied, including meat, fish, fowl, small game, mice, and insects, beside various prepared foods, such as hardtack or sweet biscuits dipped in milk and moistened with blueberries. Overfeeding must be avoided, especially at the breeding season, but a full diet for a few weeks before the pair is taken is said to make the pelts more glossy, and is a common practice. Each animal costs from \$10 to \$15 per annum to feed.

The foxes often breed when they are but 8 months old. Black vixens or females will breed 8 or 10 times in the course of a lifetime, and a litter contains from 2 to 7 or 8 pups, the usual number being about 4. During the mating season the animals are exceedingly wild and shy, and are rated a number of times as being particularly being so. There is at present considerable agitation on behalf of some kind of registration of purebred island foxes, looking toward the formation of an association of breeders for the purpose of establishing a species of "pure blood" in which to record pedigree of valuable animals. It is expected that ultimately this task may be undertaken by the Live Stock Branch of the Dominion Department of Agriculture.

# Our Latest Battleship "Pennsylvania"

## The Largest, Most Powerful and Best Protected Battleship in Any Navy

It is the policy of our Navy Department to build its new battleships in divisions of five and to make these ships in every respect identical. It is part of this policy to send each of the ships of a division in turn to a navy yard for overhaul and general refitting leaving the fleet in commission made up of so many divisions of four ships each. The Department seeks annually for a sufficient appropriation to enable it, among other things, to build so many ships of a certain type. Usually, Congress appropriates the money more or less, leaving the question of design to the discretion of the Department, where it properly belongs. Occasionally, however, Congress has gone out of its way and specified what size or type of ship it desires. This is always disastrous, for it interferes with the Department's regular programme of construction and arbitrarily introduces into the fleet a ship or ships, which, because of differences in size, speed, turning circle, or armament, cannot manœuvre effectively with the ships of the divisions to which they are allotted. The "Idaho" and "Mississippi" are a case in point. They are small "Connecticuts," of 1000 tons less displacement, a couple of knots less speed, much radius of action and other differences which greatly mar their usefulness.

When Congress appropriated last year the sum necessary for the construction of one unusually large battleship—some 1200 tons larger than any existing ship in our fleet—the Department was confronted with the old problem, and had to determine whether to make the "Pennsylvania" come into the class of the "Navada" and "Oklahoma," authorized the year before, or to constitute her the first of a new type. The "Pennsylvania" is an enlarged "Navada," and in outward appearance is so like that ship that to any but the experienced eye, she will look, when she is standing in division, to be practically identical. She will be forty feet longer, of about two feet more beam and a little more draft. Two guns will be added to the armament, giving her the powerful battery of twelve 14-inch guns. Like the "Navada" and "Oklahoma," she will have oil burning boilers of the water tube type and, probably she will be turbine driven. Her armor will be somewhat heavier and as the "Navada" and her sister are admittedly the most powerfully protected ships as yet

be of course, an increased weight of ammunition. A large part of the 1200 tons also will be consumed by the increased length of the ship and the greater weight of the frames, decks, beams and deck plating due to her increase of beam. Then there will be a very large consumption of weight due to the increased bulk of the side armor. There will be a slight thickening up of the armor plating over that of the "Navada." Furthermore the boiler and engine plant must be enlarged

are joined in transverse bulkheads of heavy armor. The barbettes are 14 inches in thickness. The sloping port plates of the turrets are no less than eighteen inches thick. The roof armor has been thickened to five inches. To protect the base of the main smokestack and prevent the escape of poisonous fumes, galleys between decks heavy armor is carried around the base.

The battery of torpedo defense guns is without any armor protection whatsoever. To place relatively thin armor on this battery is to make certain the bursting of armor piercing shells, which might otherwise pass safely through the thin plating of the ship.

Because of the wide space available due to the absence of side bulkheads, the boiler rooms are placed together under one large central smokestack.

No attempt will be made to utilize additional displacement of the ship for any great increase of the motive power and

speed. The speed will be only a little greater than that of the "Navada" and "Oklahoma" or say about 21 knots.

The "Pennsylvania" therefore will be an enlarged and considerably more powerful "Navada." Her guns will have the same arc of training and she will be so designed that she can manœuvre with the same turning circles, etc. as her smaller sister. If Congress appropriates this year for two more "Pennsylvanias," we shall have a division of ships which cannot be matched in any navy of the world.

The "Pennsylvania" embodies the combined expert opinion and judgment of the sea-going officers and the naval constructors, and the Department is to be congratulated in having produced such a fine compromise of the many conflicting requirements of the modern warship.

### Protection of Wooden Poles Carrying Electric Wires Against Decay

IN *Industria* M. Mayer proposes to protect that part of the pole sunk in the ground by encircling the critical zone of the pole (surfaces of contact between air and ground) for a variable height from 10 to 40 inches, according to the humidity and nature of the soil with a round sheet of iron, having a diameter of from 8 to 10 inches, which, when the pole, so as to have

Deck plan of the "Pennsylvania."

sometimes to drive the heavier ship, although the firing out of her lines, due to her greater length will be far to offset the increased load. Finally and very important will be the larger fuel supply with the considerable increase in weight which it will give to the radius of action.

The disposition of the turrets will be similar to that of the "Michigan," which by the way affords the most efficient distribution of the guns for securing a maximal number of all round fire. There will then be two three-gun turrets above the foremast deck, the after gun training above the roof of the forward turret and then, there will be a similar pair of turrets aft. This will give an end on fire, both forward and aft of six 14-inch and a broadside fire of twelve 14-inch guns.

The three guns in each turret will be mounted in a common house so that they will be elevated together and the three shells if there is no variation in the powder mass fall absolutely together—a matter of great importance to the shooter. There will then be four gun pointers in place of twelve and crews of men should be greatly diminished. The torpedo defense battery will consist of twenty two 5-inch guns carried chiefly on the main deck about twenty two feet above the water line. This armament will also include four submerged 21-inch torpedo tubes.

In a recent discussion of dreadnoughts before the

This "super dreadnought" 625 feet long will carry twelve 14-inch guns belted 18 inches of armor in four 16-inch gun turrets. In gun power and armor protection she is the most powerful ship in any navy.

The latest U. S. battleship "Pennsylvania" of 31,000 tons.

deduced, the "Pennsylvania," because of her size, gun power, and efficient protection, will take rank as the most powerful dreadnought built, building, or authorized by any of the leading powers.

The principal dimensions of the ship are: Length 625 feet, beam 97 feet, draft, 29 feet, and displacement on this draft, 31,000 tons. This last will be her trial displacement, and it represents the displacement of the "Pennsylvania" when she is carrying two thirds of the full supply of stores and fuel and a full supply of ammunition. Her full load displacement will be 32,800 tons.

The "Pennsylvania" will be no less than 3,000 tons larger than the "Navada." A part of this weight will be consumed by the two additional 14-inch guns and the greater weight of the two three-gun over the two-gun turrets which they replace. There will also

be a great deal of Italian architect, a distinguished officer stated that the dreadnoughts of the United States Navy were better protected than those of any other navy. Unquestionably this is a fact, and it is our divided opinion that the policy of making the protection of the floating of the ship and her main armament of paramount importance will stand us in very good stead when it comes, if it ever does, to the trial of a line-of-battle engagement.

The hull of the "Pennsylvania" is most fully protected. The main belt is eighteen feet in depth and fourteen inches in thickness. It extends far below the waterline. At the foot of it, from the armor shelf springs a 2-inch protective deck, which slopes upward to about the level of the waterline. At the top of the armor belt is an upper protective deck. The main belt extends to near the ends of the ship, and its extremities

between the outer surface of the pole and the inner surface of the sheet an empty space which is to be filled with a melted product derived from the distillation of tar and which boils at about 300 deg. Fahr. This product penetrates and saturates the critical zone of the wood and after is solidified in a uniform and compact layer, retaining however the necessary elasticity to follow the vibrations of the pole, at the same time protecting it from water and insects. Poles which have been already attacked by rot and should be exchanged, any else further use by excavating the ground around them scraping off the decayed part burning it superficially with coal oil or kerosene and using the above described method. If it is necessary to remove a pole so protected, all there is to be done is to excavate the ground on one side, bore the sheet of iron until the mass inside is melted and extract the pole.

### The Card Trick

To the Editor of the SCIENTIFIC AMERICAN

In reference to the article "Another '5th and Puzzle'" which appeared in the (October 5th, 1912) number of the Scientific American, I would advise those interested that the trick as I call it can be done with any number of piles of cards from one to five inclusive, the latter number being the best as there would be fewer cards left, and if the face cards are valued at (as usual) three added to the number of cards left will give the total of the bottom cards on the five piles.

To make this trick seem more mysterious, ask the party performing to put two cards on some pile, then count one or two on the first and second pile, and so on in any manner that you wish until the cards remaining have all been used. This is done to find out the number of cards without asking, for the more without letting anyone know that you must have the number. I find that this adds immensely to the effect of the trick.

New York City. R. W. HOWARD.

### Required, a Machine for Shaping Granite Cubes

To the Editor of the SCIENTIFIC AMERICAN

A pavement somewhat similar to that which has been in use in the streets of Liverpool for a number of years past has recently been laid in Fulton Street in this city. This pavement, which consists of small granite cubes some three or four inches across, accurately cut so as to admit of laying with close joints, seems to be better adapted than any other to meet the requirements of heavy street traffic, and at the same time affords a good footing for animals. The chief objection to its extensive use lies in the fact that the cost is considerably greater than most other forms of pavement.

It has occurred to me that those granite cubes could be produced at a lower cost if labor-saving machinery were employed in shaping them. Would you kindly call this requirement to the attention of inventors throughout the country, in the hope that they may be able to solve the difficulty?

HENRY HENRI.

Chairman Committee on Improved Pavement

New York, N. Y.  
[If the cubes are shaped by hand their relatively high cost is readily understood. It should not be difficult to devise suitable machines for doing this work. -EDITOR.]

### Determining Differences in Longitude by Wireless

To the Editor of the SCIENTIFIC AMERICAN

The paragraph in your issue of October 5th regarding the proposed use of wireless by the Belgian government for the exact determination of differences of longitude, induces me to remark that this device was successfully employed last summer by Canadian government vessels. The work was performed by the "Arctique" and "Minto" and consisted in the charting of the "Arctic" Islands at the entrance to Hudson Strait.

While one vessel remained at anchor, the other visited the various islands which compose the group. Each day the weather permitted observations from each vessel made careful shore observations for local time and date, as soon as possible these times were compared by wireless.

The distances involved ranged from thirty to fifty miles and it was found that by passing the key at intervals of a minute for four or five minutes an accuracy in transmission considerably greater than that of the observation itself could readily be attained.

The method proved satisfactory in every particular, and its rapid extension seems assured.

### The Carb Bean Tree

To the Editor of the SCIENTIFIC AMERICAN

A very interesting article on "The Carb Bean Tree" in the January 11th issue of your highly esteemed paper reminded me of my observations of this tree. It grows here in a wild state, about the bean-bearing and the male tree. The latter is used for posts of various kinds in the various parts of the country. The female develops her rapidly and has thorns from eight inches long down to very small ones on the smaller branches. The beans or pods are flat and black and measure as long as three inches and about one and one-half inches wide, the honey (sap) in the thicker portion of the pod and the beans in the thin. I have seen them over eight feet in height, and the lumbermen call them "black locust". I know of a row of the male locusts now here, about one quarter mile long, which were originally posts for a wire fence and were allowed to grow to a tree now about fifty feet high. I have also seen telephone posts made of

this variety which developed into beautiful trees. They bloom in early spring, with great clusters of pendulous, creamy white and very fragrant blossoms, the foliage is also very graceful. Cold does not affect this tree here. The locusts are very green some four or five feet from the south of us and does not stand our climate. This tree is very hard to kill by cutting down, as it will invariably put out not only suckers from its most abundant roots, but will also sprout from the stump. The soil here is rich and sandy below the surface, with a good layer of red black topsoil, the lowest stratum is gravel of an exceptional quality. In my younger days we would bind the long hard thorns to a lance of bamboo cane and use them for snake spears, and with their many tough prongs they answered admirably for this purpose. Individually I have used a smaller thorn in place of a long suspender button, the utility of which can be imagined. The male locust is also known here as "louest and wild-honey" tree. Negro children sometimes eat the honey portion, but it is never used as a food. Neither the male nor female trees are ever green here, and we are perfectly bare of trees now. I have seen these trees in Miami, Florida, in Arkansas, Tennessee, Texas, and Louisiana, besides my home State, Mississippi. It is interesting to know that there is more value attached to this tree than was supposed here.

I send you this little article for what you may wish to do with it. I have had the benefit and pleasure of being a reader of your paper and reader of your paper for twenty years, and I still look for its weekly advent with pleasant anticipation.

F. F. BERNAC.

Natchez, Miss.

### Misuse and Failure of Metals and Alloys

To the Editor of the SCIENTIFIC AMERICAN

In order to bring about a better understanding between the makers and the users of metals and alloys, I venture to request the favor of the insertion of this letter. I hope it may provoke discussion, and if possible help us to arrive at the truth.

Users, including the non-expert public of metals and alloys in general do not sufficiently realize that many of their corroded metallic ware, for example copper pans and boilers, mysterious breakages of for instance chains, railway accessories, and sudden failures of condenser tubes and copper pipes are due to two easily preventable causes—over stress and over heat.

In order to satisfy the demand for bounty of form or the modern craving for cheapness many ingenious mechanical devices have been evolved by manufacturers working under the most exacting conditions, while being made under stress or introduced in antiquated furnace appliances or deleterious compounds, which tend to and in varying times finally render the articles useless in the hands of the purchasers or users. Often enough the stress is due to human life and property. An attempt is made to remove these strains by annealing in unevenly heated furnaces.

Why this state of things?

One must reply, "general ignorance," perhaps "apathy," the major causes of most human trouble.

A few manufacturers whose products are subject to constant physical tests are quite alive to the situation. It must also be conceded that manufacturers of ferrous and non-ferrous metals and alloys spare no pains to free their ware in the molten state from deleterious substances. They employ expensive means known as deoxidizers—ingenuous devices to prevent contact of the liquid metal with the air during the casting operations, all tending to free the metal from the deleterious impurities which are then from blowholes and segregations.

No sooner is this desirable end attained than the metal or alloy is introduced into furnaces whereby hot gases containing free oxygen, sulphur and other objectionable substances are allowed to impinge upon the surface of the metal. While hot, they are brought out of the furnace into the air and mechanically treated in an atmosphere containing oxygen. This operation is often repeated several times. In case of cold working, the metal, with few exceptions, is annealed between processes in furnaces to which the air has access. After the heat treatment they are withdrawn and allowed to cool, sometimes in approximately closed receptacles, often in the air. Not only is the surface of the metal exposed to impingement during the time of heating, and partly in cooling, but during of oxygen and other gases take place, with formation of compounds in intergranular spaces, or in the body of the metal or alloy, which form centers or areas of corrosion which are dangerous to human life and property.

In the last year or two exact investigations and experiments have proved beyond doubt that both the above defects in heat treatment are prolific causes of corrosion and the other breakdown.

It is with this respect but leave to submit that the time has arrived for all engineers and users of metals and alloys to insist and specify that, at least, two causes of failure of metals and alloys under the control of the makers shall be removed, namely: (a) Uneven heating (b) The deleterious heat treatment in chemically and physically active atmospheres.

Indoubtedly the public health will benefit, because all the appliances on the market capable of bringing about the above results are useless when in operation. The present recovery and twisted words of one of our natural resources, viz.,

T. V. GARDNER, A.R.M.S., Birmingham, England.

### Bursting of 13.5-inch and 14-inch Guns

To the Editor of the SCIENTIFIC AMERICAN

In your number of December 14th last, when speaking of the bursting of a 13.5-inch gun, which had taken place a few days previously, you alluded to the force controversy which had taken place a few years ago, respecting the question of the relative strength of the wire-wound gun and hoop gun. Starting from the justified assumption that the hoop gun which burst was wire-wound and of the most recent pattern, you recalled to mind that "the advocates of wire-wound construction claim, or did claim, before the recent improvements in hoop guns, that the wire-wound gun, because of the absolute insensibility to every part of it could be subjected, was proof against the kind of accident which recently happened at the proving ground."

From the wording of the article it results clearly that you had doubts as to whether the claim of the manufacturers of wire-wound guns were well founded, and I presume that these doubts will have been further strengthened by the bursting of a 14-inch wire-wound gun which took place at the Sandy Hook proving ground on December 6th.

The Report of December 14th, the gun, after having fired a first shot with reduced charge burst at the second discharge with a normal charge of 320 pounds powder and a projectile of 1500 pounds producing a pressure of 22,000 pounds per square inch, while the contract strength of the gun called for a minimum of 55,000 pounds.

This is quite an extraordinary event, which, taken together with which had taken place in England, where the 13.5-inch gun burst at the seventh discharge, shows that the criticism against the wire-wound gun is well founded, and that it is, in fact, not true that the latter have a circumstantial strength greater than that of the hoop gun.

That the wire-wound gun is very defective as regards longitudinal strength is a matter which is now so well known that there is no need to demonstrate it, and in connection therewith it will be sufficient for me to refer to the "Memorial de l'Artillerie" which is the subject in the February-March number of the Journal of the United States Artillery.

As regards the circumstantial strength, I beg to call your attention to the two important articles which were published in the "Memorial de l'Artillerie" in 1912 by the ordnance and naval engineers Messrs. Leon Coupage and Pierre Malaval.

These two gentlemen have exhibited, by different methods, the properties, the following proposition: "When ever may be the system according to which a compound gun is constructed, whether it is hoop or wire-wound, the internal pressure which it can resist without altering its shape permanently has as its upper limit the value of the limit of elasticity of the metal of which its internal tube is manufactured."

Thus, for instance, a gun the inner tube of which is manufactured of a metal with a limit of elasticity of 40 kilos, cannot resist, without a permanent deformation, an interior pressure exceeding 4,000 kilos per square centimetre (56,801 pounds per square inch). This limit of internal pressure can, however, be reached only in case the internal tube is of infinite thickness. It is low in practice, and decreases with the thickness of the tube.

In the wire-wound gun the internal tube is of small thickness and strongly compressed by the steel ribbon surrounding it externally. The limit of elasticity of the ribbon is superior to that of the tube, and consequently under a given pressure, the latter suffers an elongation greater than that of the ribbon. When the entire arrangement returns to its state of repose, the tube can no more retain its former dimensions, because it does not find the necessary space to do so and, consequently, contracts or breaks. The same applies to the hoop gun.

I think that to this cause must be attributed the bursting of the English 13.5-inch gun, as well as that of the American 14-inch gun, and it seems to me that these two accidents, which took place within a few days of each other, must give rise to serious questions.

ERNEST BLAVETTA,

Captain Italian Royal Navy (retired)

[The theory of our correspondent regarding the cause of the bursting of the 13.5-inch gun is decidedly interesting. He is wrong with regard to the American 14-inch gun. The cause of its bursting was the same which we cite and as likely to disclose.—EDITOR.]

Three explorers who have made Antarctic history

## The Scott Expedition and Its Tragic End

### A Sacrifice Made for Scientific Ideals

IN the desolate, icy waste of an unexplored Antarctic country Capt. Robert Falcon Scott gave up his life, after having reached the South Pole. He died a true hero of science. There was no buried treasure to seek in those untrodden southern snows—nothing but ever lasting fame. Only those who are engaged in scientific research can understand the ideals of a man who will fight his himself off from the world for a period of three years and perishes in a blizzard—for what? For meteorological information for geological data for light on the fauna and flora of a cold, white, silent land that will probably never be peopled, for a handful of rocks and fossils that will show the relation of the Antarctic Continent to North America and Australia for a study of the southern atmosphere and the southern seas, in a word for things that are infinitely removed from gold hunting.

Let it not be supposed that the cause in which Scott died was the mere attainment of the South Pole. If that athletic feat, as it has been termed were the only object of polar exploration scientific societies would not contribute a penny to the equipment of an expedition. Nor would men of Scott's and Shackleton's attainments be interested in it. A polar dash makes good newspaper reading, but your scientific geographer looks primarily for some addition to the world's knowledge.

#### The Great Unexplored Antarctic Continent.

Until the close of the nineteenth century there was no part of the world about which less was known and none about which so little interest was manifested as Antarctica. The reason is to be found in its distance from the centers of wealth and thought, in its dearth of animal and vegetable life, and in its unpopulated state. The game hunter, the daredevil explorer seeking adventure found little to attract him in that bleak and barren country. It was a region that held a fascination only for the scientificist inclined, and hence we find that most of the men who have braved its terrific blizzards have been men of the finest scientific type.

Positive knowledge of the Antarctic regions was acquired very late in the nineteenth century. Indeed, to Capt. Scott belongs the credit of having first penetrated Antarctica during his last expedition of 1901 to 1904. Before that

time geographical knowledge of the South Polar regions was confined largely to sea approaches. To be sure Palmer Land with its associated islands, the coast of Victoria Land with the adjacent Ross sea and to a lesser extent, the coast of Wilkes Land had been explored, but of the great Antarctic continent as a whole, practically nothing was known before Scott's first expedition returned. True, the examinations of the Belgica, the Franconie and the Pourquoi Pas showed that Palmer Land extended away to the southwestward along the southern confines of the Pacific Ocean, and the German Goese, which the first expedition confirmed the discovery of Wilkes, made in 1840 and so long discredited. But the first who really scaled the Great Barrier and gave us some idea of a continent whose present unexplored and unvisited extent is still twice the area of Europe was Scott. Thanks to his studies, supplemented by those of

Shackleton we know that in former geological times the continent was probably connected with Africa, South America, Australia and New Zealand although not with all of them at the same time. The first phase of any journey which has for its object the exploration of this vast territory must be over the plateau of the Great Barrier, the second a climb through mountain passes, and the third a traverse of a lofty inland plain. Not all the explorers who managed to ascend the Great Barrier could take any means of transport with them. Sir Ernest Shackleton had to advance with the umbril's efforts of man alone. His party started on the second phase with full loads, and achieved what is probably the maximum that could be accomplished under such circumstances. Amundsen was able to use dogs because of the more or less favorable conditions which he encountered. Perhaps this fortunate circumstance may in large measure be attributed

But even if ponies, dogs or motor sledges can be used it must be remembered that the last phase of the journey owing to the height of the plateau must inevitably be accomplished under climatic conditions which for severity are unequalled either in the Arctic or Antarctic regions. Polar exploration must be conducted with a technique of its own a technique that differs at both extremities of the south for the simple reason that the topographical conditions are not the same. In the north we find islands and a polar sea. In the south an austral continent surrounded by a narrow fringing ice cap which is called the Great Barrier and which covers probably more than 150,000 square miles of the Antarctic Ocean. Sledging is, of course, necessary in both regions. In the north it is not possible to travel by sleds over the frozen sea except during a short period in spring. In the south sledging is more or less possible at all seasons except that the meteorological conditions are more favorable at some times than at others.

#### The Importance of Equipment

Next to the personality of the leader, equipment is the most important element in the success of polar exploration. The Japanese expedition under Dr. Shirai failed because of its poor outfit. Amundsen was not equipped to fight as well as Scott. Personal courage and will counted for more in his

The South Pole lies on a lofty eminence. How it was attained by Amundsen on December 14th, 1911, and by Scott on January 16th, 1912, is indicated on this map, together with Shackleton's course in 1909.

Amundsen and sleds plodding along toward the Pole. This picture was taken by Amundsen only a few miles from his goal.

Photograph of Lieut. Helmer Hansen taken by Capt. Amundsen at the South Pole with one of the dog teams.

more than anything else. Lieut. Flikner, the head of the German expedition now in the South Polar regions conducted his unrelenting work with true German deliberation. First he carried out an elaborate campaign of oceanographic work out in the South Atlantic, and then a series of very interesting meteorological observations with sounding balloons in South Georgia. Finally on the 10th of December 1911, his ship the *Deutschland* set sail for Antarctica where it expects to remain until the winter that is the southern summer 1911-12. The *Deutschland* is equipped with wireless.

It may be that Lieut. Flikner's expedition is better equipped than that which Capt. Scott left. In the other hand, we are informed that Scott spared no time, energy or money in order to fit out his party. Its popular subscription the sum of \$250,000 was raised. He is believed for his ship the *Terra Nova*, the largest and the strongest of the old Scottish whalers built at Dundee in 1884, she is 187 feet in length and 11½ feet in beam and is considered the best ship ever launched for the Greenland whale trade. Of late years because of a decline in the whaling business, she has been engaged in seal hunting in the northern waters, selling from St. John's, Newfoundland.

The *Terra Nova* however has not confined herself to the humdrum of trading. In 1903 she was purchased by the Admiralty as a relief ship for the Discovery expedition and after being considerably strengthened she duly made her appearance in Ross Sea. The year 1905 saw her in the service of a North Polar expedition on a visit to Franz Josef Land. Thus she has ranged from the great ice barrier in the south to the North Polar pack—from extreme to extreme of the inhospitable waters of the globe. The size and strength of the ship make her a

Franklin, one of the camps of the Amundsen expedition used as a house of supplies.

fitting receptacle for the extensive equipment which it is necessary she should carry for success.

#### Scott's Equipment.

In equipping his expedition Capt. Scott displayed painstaking care. He laid great stress on the fact that the newly devised motor sledges offered a new means of ice travel, and three such sledges were stored in the hold of the *Terra Nova*, as well as an equal number of the more familiar dog sledges. In a final statement before the expedition started Capt. Scott thus summarized the difficulties of Antarctic travel.

The problem of reaching the South Pole from a wintering station is partly one of transport. The distance to be covered there and back is about fifteen hundred miles. The time at the disposal of an explorer in a single season never exceeds one hundred and fifty traveling days. An average of six miles a day can really be maintained by men of good physique, provided adequate transport facilities are made.

There are three means by which the traction for heavy sleds loads can be provided: via ponies, dogs, and motors. As a result of two years' experiments, a motor sledge has been evolved which has undergone satisfactory trials on the snows of Norway. A motor was recently taken on Mr. Shackleton's expedition and it is instructive to note that it was found possible to run it in the low of temperatures. Its use on a prolonged journey was prohibited only by the fact that its wheels were not sufficient to support it on the soft snow of the barrier.

The plan for the journey to the south pole from King Edward VII. Land includes the use of the three means of sledge traction described. Ponies will be taken in sufficient numbers to insure a thoroughly adequate supply of food and will be used for transport to the foot of the glacier; a dog team with a relay of men will transport the loads over the glacier surface; and a picked party of men and dogs will make the final dash across the inland ice sheet. Motor sledges will be used according to their proved capacity as a main store or mortal auxiliary in the transport plan. If they reach the foot of the glacier there is little doubt that they will succeed in

The junction of the Great Barrier and King Edward VII. Land about 300 feet in height. The Barrier here appears

and greatly simplify the difficulties of the remaining journey if they could reach the glacier they will, at least, as far as the other considerations, relieve the pain and ease of the weight, and the safety of the return journey, as they may be enabled, when no longer available, to await the return of the party.

### Scott's Programme

In a letter delivered in London before his departure, Scott presented the following programme:

Now clear, SCOTT MAPPED OUT AS FAR AS WAS POSSIBLE THE PLANS FOR THE BRITISH ANTARCTIC EXPEDITION

Departure from London	June 1st, 1910
Cape Horn	June 15th, 1910
Cape Horn	August 1st, 1910
McMurdo	September 11th, 1910
New Zealand	October 17th, 1910
Leaves New Zealand	end of November, 1910
McMurdo	end of December, 1910
Leaves McMurdo	end of December, 1910
Return to McMurdo	January 21st, 1911
Return to England	February 21st, 1911

Departure of this party about January 21st, 1911  
Return to England about January 21st, 1911

Departure of second hut and travelling equipment for party of six men on King Edward's Land

Departure of provisions to be left on edge of Great Ice Barrier to form link between eastern and western parties

Departure of party to turn northward about February 21st, 1911

Investigation of the pack in the region of the Bailey Islands, and to proceed to the westward through the south of those islands

Departure of party to the south on the Great Ice Barrier

Start for the South Pole to be made during the month of October

Return to be traversed and the Beardmore Glacier ascended during October and November 1911

Capt. Scott (seated) and his first officer, Lieut. Evans.

By courtesy of Messrs. and Mrs. Scott.

Capt. R. F. Scott in polar costume.

Capt. Scott, on January 3rd, 1912, when he was one hundred and fifty miles from his goal wrote of his plans in a message he sent back. He said:

I am going forward with a party of five men, leaving three back under Lieut. Evans with this note. The names and descriptions of the advance party are: Capt. Scott, R. N.; Lieut. Wilson, chief of the scientific staff; Capt. Davis, Indian Medical Department in charge of the party; Lieut. Royds, Indian Medical Department; and Lieut. Evans, R. N., in charge of sledges and equipment.

The advance party goes forward with a month's provisions and the prospect of success seems good, provided the weather holds and no unforeseen obstacles arise.

### The Tragic End.

Capt. Scott and the four men with him reached the

from conclusion of the brain on February 17th, 1912. Outset from exposure on March 17th, 1912. The remaining three men made their way back to within 105 miles of Cape Evans, when they were caught in a blizzard that must have lasted nine days, and were overcome about March 20th within eleven miles of the shelter and supplies at One Ton Camp.

The relief expedition recovered the records of Scott. He had found the tent and documents left by Capt. Amundsen when the Norwegian left the pole about a month earlier.

Scott's total distance to the pole and back was 1,942 statute miles.

The death of Capt. Scott, chief of the British Antarctic Expedition, was a tragedy in the history of the world. Despite his badly frostbitten feet and hands, he struggled on manfully. On March 16th his comrades knew that he was doomed. For weeks he had suffered in misery without complaint. No wonder that Scott wrote in his diary:

It was a brave soul. He slept through the night hoping not to wake, but he awoke in the morning. It was blowing a blizzard. He said: "I am just going outside and may be some time. I've went out into the blizzard and I have not seen him since."

There is only one construction to be placed upon this passage. One knew that he could not live. He knew that as a sick man, he was an impediment and the chances for the survival of the rest were better with himself out of the way. Bravely he stripped out of the tent and into the blizzard, never to be seen again.

In the last tent pitched in the party a final message in Scott himself was found. Written with the shadow of death upon him, his pathic appeal had deeply moved the civilized world. We reprint it here from the columns of the New York Times.

### Message to the Public.

The causes of this disaster are not due to faulty organization, but to misfortune in all the risks which had to be undertaken. The loss of my transport in March 1911 obliged me to start later than I had intended and obliged the limits of staff transported to be narrowed. The weather throughout the outward journey and especially the long sea, in 40 degrees north stopped me. The soft snow in the lower reaches of the glacier again reduced my pace.

I fought this outward voyage with will and courage, but it ate into our provisions faster. Every detail of our food supplies, clothing and dog-sleds made on the interior coast and on that long stretch of 100 miles to the pole and back worked out to perfection. The advance party would

By courtesy of the British.

It was here that the 1910 expedition lived after the ship landed them on the Antarctic continent. The internal arrangements are here only approximately given as the final divisions of the hut were a little on the Antarctic coast.

Upper party to be reached early in December 1911. South Pole to be reached if possible on December 22nd, 1911. Adverse conditions prevented him from living up to the schedule. He was delayed from four to six weeks in making the preparations for his polar dash.

### The Journey to the Pole.

Scott's actual start for the pole began on November 2nd, 1911, later than he expected. His plans and hopes were last described by himself, and the version was brought back by the "Terra Nova."

The party consisting of myself with Wilson, Oates, Bowers, Harcourt, Williams, Wright, Evans, Trevelyan and Ross, will start about November 1st. Independently of the success of the motor, parties will be worked with light loads in every march to the coast camp, with full loads and heavy sledges to One Ton Camp and with such pressure as necessary thereafter. Dog teams starting will pull up to One Ton Camp and help to advance loads. By these means we hope to get thirty units of food to the foot of Beardmore Glacier, a unit being a week's provision for four men. Then with three divisions of four men and twenty-one units of provisions, I hope to extend the advance to the required distance. If the weather conditions are not wholly unfavorable.

Of the ten remaining parties one is unreliable and one doubtful. The remaining being in very fine form. Officers and men are in splendid health and eager to go forward. Owing to my decision to postpone there is an obvious chance that the most advanced party will be unable to reach the Terra Nova before she is forced to quit the coast under these conditions, having regard to important scientific work done and facilities offered for further work. I have decided to maintain the station for a second year. The majority of the shore party will probably remain, but details depend upon the date of our return from our journey on home sledge and the extent of fresh transport provided.

On November 24th Capt. Scott wrote that the party arrived at Corner Camp. Just before One Ton Camp was reached the dog sled party caught up with Capt. Scott's party and they journeyed in company. They passed the abandoned motor sleds, and when they found the motor sleds waiting at latitude 80°4' they learned the motor had been left behind because of the over-heating of the air-cooled engine.

on January 15th, 1912, but on the return journey all perished. Their bodies were not found until a searching party went out on October 18th discovered them on November 12th nearly eight months after the disaster. In latitude 79° degrees 10 minutes south and longitude 120° degrees 25 minutes east. Evans died

By courtesy of the British.

The "Terra Nova," prepared and provisioned for her journey.—A fore-and-aft section. The numbers refer to the following: 1. Plans; 2. Pantry; 3. Instrument room; 4. Fuel room; 5. Reservoir for fresh water; 6. Ventilator; 7. Store; 8. Biological locker; 9. Storehouse; 10. Transport store. The motor, sledges and dogs are to be taken aboard at Lyttelton. The dogs will probably occupy the fore-castle.

Ready to descend in a diving helmet

### Painting the Wonders Under the Sea

An Artist Who Works Under Water

By Charles M. Carroll

**M**R. E. H. PRITCHARD, an artist now working in California, devotes his life to painting pictures under water. He holds that it is impossible to catch the colors and what might be called the atmosphere of submarine scenery by any method of observation from the surface. Even when the disturbing effect of the broken surface of the water is eliminated by using a glass-bottomed boat or tube everything appears unnatural and distorted to the beholder. Mr. Pritchard goes down to the bottom of the ocean wearing a diver's helmet, and makes sketches on waterproof paper with waterproof crayons. The paintings are then completed in his studio.

Mr. Pritchard is an Englishman by birth. When still a boy he made for himself a pair of water-tight goggles, similar to those worn by the famous pearl divers of the South Seas. These goggles are merely bits of cow horn cut and shaped to fit the eyes. They allow a small space of air between the eyes and the water so that one can see very well. With these goggles the young man studied the landscapes under water with a clear vision. His imagination had been fired by Jules Verne's "Twenty Thousand Leagues Under the Sea," but he speedily discovered that it was impossible to shoot birds from the sea bottom as Verne asserted, as the sky is rarely glimpsed by the diver and then only by looking directly upward, for at a moderate angle the surface becomes a silvery mirror reflecting the silent cities of coral and the lone, grotesque figure of the diver.

Mr. Pritchard became a diver in England and a very successful one. He had preserved a few sketches made from memory of the scenes under water and showed them to some critics but when his fellow artists ridiculed his work he became discouraged.

About this time his health failed, and his doctors ordered him to go to Egypt. Instead he went to

Mr. Pritchard ready for work when using the "diver's goggles," the latter shown suspended about his neck.

Coral-eating chaetodon, off Tahiti

Painting showing sand heaps on the bed of the sea.

Paltil one of the South Sea Islands where he learned the most wonderful coral formations in the world were to be found. Arrived there, he decided to take up actively the work of painting the under water world.

His process at first was comparatively crude. He would go out in his boat with his helpers, find his country with a glass-bottomed box and descend by means of weights hooked to his waist. Then he would make mental notes of the rock or coral formations, ascend and paint them. But this method proved unsatisfactory. He wanted to make actual sketches under the water.

After seemingly endless experimenting he discovered a way of making waterproof paper by soaking extra heavy drawing paper in coconut oil and draining off the surplus. This after drying proved to be a good working surface. Mr. Pritchard fastened it to plate glass which served as his drawing board by means of surgical tape. In order that the water might not come under the paper and wrinkle it, he used Baffin's crayons and solid oil paints which are especially adapted to submarine painting.

After putting on his diving dress and goggles, he would take a good breath and lower himself down in the water using a heavy lump of coral attached to his belt by means of a hook to keep him down. Arrived at the bottom he would sketch from 30 to 45 seconds then inhale the piece of coral and ascend for breath. The coral was then drawn up by means of a rope for another descent. In this way he was able to complete his sketches after a number of descents. Nowadays he uses a diver's helmet and is able to complete his sketch in one descent.

Thus he works, clad in his clumsy diving suit, sitting on a rock and surrounded by the wonderful tropical fish. Of these fish Mr. Pritchard is enthusiastic. The fish of many varieties, from some so tiny that many of them together can be carried on his thumb and to huge monsters that drift slowly and ominously past. There are the bluish, coral-eating, chaetodons. The

### Safety Lath Dog

THE accompanying engraving shows two forms of lath dogs one the common form and another the improved form adapted to avoid danger of injury to the operator of the lath. In the common form of lath dog the set screw is disposed on the opposite side of the eye from the arm that engages the face plate. With this construction there is always the danger to the operator of being struck by the sharp edge of the head of the set screw or by the projecting arm of the dog. In the improved form of lath dog, this danger is avoided by having the arm curved around toward the set screw so as to serve as a shield for it. Thus it will prevent the cleaver or chisel of an operator from being caught by the set screw and even if the operator's hand is struck by the arm, the blow will be more in the nature of a push, owing to the curved form of the arm.

Safety lath dog

Device for recording the "popping" of a safety valve.

Fire alarm operated by variation of temperature.

### Waste Steam Detector

A LTHOUGH many firemen on locomotives labor under the impression that the boiler they keep their fires the better firemen they are. Hence they force their steam up to such a pressure as to keep the safety valve constantly popping or blowing off and realizing that the steam which pours out represents an actual waste of water and fuel. It is estimated that it takes a quantity of a pound of coal to produce the amount of steam that escapes through a valve three and a half inches in diameter for each second of such wastage. This amounts to five pounds of coal per minute or approximately half a ton of coal per hour. With larger safety valves the waste will be proportionately greater.

Heretofore there has been no way of determining how much fuel is wasted in a given time in the operation of an engine, but an inventor has recently designed a device which keeps a record of the time during which the safety valve is blowing off. The recording device is kept locked so that it cannot be tampered with and at the end of a run an inspector can unlock the device and determine the exact number of minutes during which the steam was blowing off. The inventor claims that from experiments so far made by the use of his device a waste of an average of over two tons of coal has been saved in a ten ton run.

The device is attached to the coupling of the safety valve as shown in the engraving. It consists of a clock mechanism with two concentric, graduated circles, one for the minute hand and one for the hour hand. The circle for the minute hand is not only divided into minutes, but it is also marked with the equivalent in the pounds of coal of the steam wasted during the corresponding periods of time. Similarly the circle for the hour hand is marked off with the equivalent loss in tons of coal. A lever mounted on the device carries at one end a brush which is adapted to engage the escape wheel of the clock mechanism with a broad blade on the other end rests on the pointed top of the safety valve rod. When the valve blows off the steam hits this blade drawing the brush out of contact with the escape wheel and permitting the clock mechanism to run.

At the start of a run the instructor sets the clock hand to 12 o'clock

and then looks the ending of the clock. At the end of the locomotive run he can determine at a glance the length of time that the safety valve has blown off during the run, and also the equivalent amount of coal that has been wasted by the fireman.

### A Novel Counter

ALFRED H. UNDERHILL writes that in his city they have smooth asphalt

streets and many hills adapted for coasting. Recently the boys have produced, in large numbers, home-made counters consisting of narrow boards about 4 feet by 2 feet by 2 feet to 3 feet, the underside of which near each end are fixed one pair of the rollers from a roller skate. On the front of this bar is secured a small packing box extending up about ten or twelve inches, and on top of this is secured a bar which projects laterally at

both sides to form a handle. By this, when momentum is once secured, the slide vehicle is stabilized so it will maintain the upright position just like a bicycle. Naturally the box obstructs the view of the roadway, and it is believed that this device can be developed into a most useful device that can be cheaply produced and should prove a popular and profitable toy.

### An Automatic Fire Alarm

THE earliest automatic fire alarm was virtually thermometers arranged to close an electric circuit when a dangerously high temperature was reached. The objection to this form of alarm lies in the fact that it is liable to be operated where there is no fire, as by an accumulation of heat in some badly ventilated spot, or again, it may fail to operate where there is a fire until the fire has gained considerable headway, merely because the temperature at the particular point where the automatic device is located may not happen to rise to the point for which the device was set. The apparatus shown in the accompanying drawing overcomes this difficulty. It operates to close an electric circuit when there is a sudden rise of heat. In other words, it is not the degree but the variation of temperature that affects the apparatus, provided the variation is sudden. The device consists of a metallic chamber 4 which forms an air reservoir. In the side of this reservoir there is a small pipe B, which serves as an air vent. Stretched across the upper end of the air reservoir is a diaphragm C which carries a stem D that bears against the leaf spring E forming one terminal of the electric alarm circuit. The other terminal consists of the platinum pointed screw F. Now in case of a sudden rise of temperature, the air in the chamber A is rapidly expanded so that it raises the terminal B into contact with the terminal F, closing the electric alarm circuit. This may be a gong or an automatic striking device. In case of a gradual rise of temperature, the expanding air in the chamber A escapes fast enough through the tube B to prevent flexing the diaphragm.

The apparatus is so sensitive that the heat of the hands when applied on the chamber A will cause the alarm to ring, and yet if the device be located above a kitchen range, the heat of the range will not cause the alarm to be set off. However, if a piece of newspaper be set on fire on top of the range, the alarm will immediately be sounded.

### Recent Improvements in Machine Tools—III

THE recent enormous activity in the automobile industry has given rise to a great demand for transmission gears to be used on automobiles. There has consequently become a great demand in factories where there is a large out put for this industry, for a means whereby square, hexagonal, octagonal or other polygonal holes may be cut in the gears, automatically, rapidly and with accuracy.

A H. Marsh of Jackson, Mich., has recently patented a machine which is adapted to cut such holes in gears, plates or other work.

As seen in FIG. 1, the machine is a duplex one, the same driving mechanism, including the cone pulley 3, pinion 4 and gears 5, serving to operate the two shafts 6. The

This machine has been designed to meet the great demand for turning out automobile transmission gears quickly and cheaply. There is a great demand in factories for a means whereby square, hexagonal, or other polygonal holes may be cut in the gears automatically, rapidly and with accuracy.

## G. V. Electric Trucks

### With Underslung Battery

Below we illustrate a  $\frac{3}{4}$  ton G. V. Truck in the service of the Metropolitan Engineering Company, Brooklyn, New York. The truck has a rated mileage of 40 miles per charge, but that is not maximum and as it is provided with an underslung battery, the rated mileage can easily be doubled.

A fresh battery can be substituted by the underslung method in from 5 to 10 minutes. The truck is driven over a pit, the old battery dropped and the new one lifted into place usually by hydraulic power. Several prominent firms, among them a department store, a wholesale provision house, and to mention numerous Central Stations, are using the underslung battery with unqualified success.

Before you buy Motor Trucks, consult the world's largest manufacturer of Electric Trucks. One with a product standardized five years ago, one with simple resources and an engineering corps which can meet yours on its own level.

See capacities, 750 lbs. to 5-ton. Catalogue 101 and comparative cost figures on request.

## Sure--Simple--Saving

### is this Unique Oiling System

Oil is cheaper than parts.

So the Huppengine engineers have devised an ingenious system whereby oil is positively fed to every part and point where it is needed.

The Huppengine system, through force feed escapes the complication of the pump, because the motor driven pump supplies the pressure and the uncertainty of the splash, because tubes and ducts of simple easy carry the oil to bearings, gears and moving surfaces.

The force feed running in oil throws the oil up into a cup or tube which carries it to the regulator and distributing system.

The oil is conducted to the main crankshaft bearing by three tubes, and by ducts drilled in the crank shaft itself to the crankpin bearing.

Spray from these as the shaft revolves, lubricates the crankshaft, and the cylinders under ordinary

conditions; but as an added protection system leads conduct of directly to the cylinders.

So much for efficiency. Now we come to economy.

The force feed cuts down oil use to the minimum amount, and the oil is not wasted.

Thus, the Huppengine system of force feed is a method of saving oil and saving money. The oil is not wasted, and the engine is not damaged.

The oil is not wasted, and the engine is not damaged.

## The Motor-driven Commercial Vehicle

This department is devoted to the interests of present and prospective buyers of motor trucks and delivery wagons. The Editor will endeavor to supply any questions relating to mechanical features, operation and management of commercial motor vehicles.

### Where the Motor Bus Beats the Trolley

By J. R. Eastie

WHILE the United States leads the world in the number of motor trucks having more in service than any other two countries combined there is one type, the motor omnibus, in which England, France and Germany lead this country by a wide margin. It is hard, in fact, for us to truly appreciate the extent of the motor bus service now provided in the cities of London, Berlin, and Paris.

The largest company operating in London, for example, now has over 1,500 motor omnibuses in service. This is the London General Omnibus Company and its installation of motor vehicles is the largest in the world. This company for many years owned 14,000 horses and over 2,000 horse-drawn buses, but these have now been entirely discarded.

This company carried in the past year 216,000,000 passengers, or about 25 per cent. less than the 267,000,000 passengers who rode in the New York subway during the year ending last December. The lack of a comprehensive system of surface electric cars in London, of course, favors the use of motor omnibuses.

That the motor omnibus has decided advantages over the street car, and will largely displace the latter, is indicated by figures now available for both the London County Council and the London General Omnibus Company. The former, operating tram lines under a \$30,000,000 capitalization, obtains a route mileage per day of 120 miles per day while the latter, with \$11,200,000 capital, gets 170 miles per day. For February of this year the bus companies' business showed an increase over the corresponding period of 1911 of 21 per cent., while the tram lines gained only 6 per cent. The motor omnibuses are therefore, not only proving more popular with the traveling public, but evidently return larger dividends.

### What Motor Trucks Have Saved for a Brewer

By Jean E. Blaise, General Superintendent of the Pater Dooling Brewing Co.

WE have sold every horse we owned, we let the last one go May 2nd 1912. Now when our ashes are disposed of by means of a motor truck.

We bought our first 5-ton electric truck in 1904, merely as an experiment. We did not buy again until 1909 when we bought three. A few were purchased in 1910 and in 1911 we bought five more. We are satisfied that with the improvements in truck design and our better knowledge of electrically routing out deliveries, the motor truck was a paying business proposition. Accordingly in 1911 we bought '35, the majority of them all 5-ton capacity and this year we have already purchased 20 more giving us about 60 electric vehicles altogether. Then of course we have 18 gasoline trucks for our extra long hauls.

We sold our first horse in the fall of 1910, and sold more and more as the trucks came into service. We have sold 170 altogether as a direct result of installing motor trucks, and I know it has been a wise thing for us to do. We had the best horses and wagons that money could buy, and good capable drivers who were able to do long periods, but the motor truck is the only thing for the up-to-date brewer. At least for the one who realizes that money saved in distribution is as important as that saved in production. We have reduced the cost of delivering beer in Greater New York from 35 cents per barrel to 10 cents per barrel, and this within from 8 to 10 miles from the brewery. Our whole delivery system

has been revolutionized, and in place of famous state wars we have a few pennies which has saved us indirectly, half a million dollars in real estate alone.

We had a stable 200 feet wide fronting on East Fifth Street, and back of it three wagon yards and some other buildings, used just for our horse equipment. We tore down half of the stable, converting the rest of it to other uses, and built on the ground so released a big bottling plant. In one of the wagon yards we built a garage for our trucks, 85 by 100 feet, and this is all the ground necessary to house 100 trucks, because we only need five stories over for that. The long and short of it was, we were saving about twenty-eight city lots worth from \$15,000 to \$20,000 each. And that isn't all the money we saved. In addition, the saving of from 18 cents to 20 cents per barrel on beer delivered, plus the saving on drivers, adds up to between \$65,000 and \$75,000 per year.

We haven't completed nearly all our plans yet. Inside of another year, we shall establish four depots in Greater New York, delivering the beer from the brewery to the depot with heavy trucks and distributing it from these centers with power vehicles. By this method, we expect to operate electric trucks exclusively, as we believe electricity is going to supplant other forms of power in the industrial world. Year by year we drive more machinery and appliances in our brewery with electricity, and as there are good reasons for doing this. Things reached a point where it cost us 96 cents per day to feed and care for each horse in our service. We knew we had to find a solution for the expense as a matter of business and that principle applies to other things as well. Two men with salaries aggregating \$44 per week care for all our motor trucks, so you see the difference.

### Cost of Gasoline Truck Service

TO THE EDITOR OF THE SCIENTIFIC AMERICAN: In the SCIENTIFIC AMERICAN of JANUARY 1912, we note with considerable interest the article by Mr. H. W. Perry entitled "Trams and Motor Trucks Compared." We buy to take exception to the figures he gives, as he assumes that full loads are always hauled both ways, which is very rarely the case. It is very seldom that full loads are carried half the distance the truck travels.

You can readily realize that if the truck starts out with a load of merchandise and has to make a delivery by the time it reaches its furthest point it will be empty and will return in that condition. With contractors full loads are often carried to destination and then the truck returns empty. With brewers and allied industries full loads are often taken to one point and a load of empties brought back, and these are the people that generally have the greatest ton mileage.

So you will see from this that it is not possible to figure out ton mileage unless the exact conditions are known. This term is often used, and with brevity it is used correctly. We consider the cost per mile a more reliable figure.

We also notice "Cost Estimates of Horse and Motor Trucks" by Mr. John W. Little in your long period, but the motor truck is the only thing for the up-to-date brewer. At least for the one who realizes that money saved in distribution is as important as that saved in production. We have reduced the cost of delivering beer in Greater New York from 35 cents per barrel to 10 cents per barrel, and this within from 8 to 10 miles from the brewery. Our whole delivery system

pears in your issue of January 14th last. The pictures given on the front cover and on page 70 of this issue to accompany the articles by Messrs. Perry and Hiltchris bring out in quite manner some of the comparative properties of motor trucks and horse-drawn wagons. But I do not believe the two comparisons are as discrepant as suggested in your editorial entitled "Comparing the Incomparable," and I desire to take this opportunity of pointing out wherein the view points of the articles differ.

The article by Mr. Perry considers only the "possible" work by gasoline motors and by horse wagons. The daily mileage cited for horse wagons (16 to 20) is approximately what they are to-day traveling in city service, the mileage of 40 to 50 per day as mentioned for motor trucks is being covered by those motors which are in comparatively long haul services, but is impossible by even high speed cars in a great portion of urban work. The service in which motor trucks cover more than 30 miles per day are admittedly too severe for horses, and most of them were not performed by road vehicles before the advent of the automobile. A comparison of the cost of moving a ton over a mile under the two sets of circumstances is not logical, any more than it is logical to claim a superiority for the railroad which hauls between Chicago and New York at a lower ton mile operating cost than the road which hauls between New Haven and New York.

Instead of stating the possible performance of motor and horse wagons in entirely different services, it would seem desirable to consider their relative performance when used in the same service and under the same conditions. This was the basis of the data reported in Mr. Hiltchris' article. As stated in the text, particular services were selected for each size of wagon and the territory covered in each case was assumed to be within four miles of the loading points. The results of comparing the horse, electric and motor wagons show that in this limited area the horse wagon is by no means out-placed, particularly in the lighter aspect view.

The reason for this deduction, which is referred to in your editorial as "wanting" is not hard to find. It is the amount of standing time required by our present delivery methods, as horses are seldom moving more than 50 per cent of the working day. The chief superiority of the motor truck over the horse wagon is the higher speed which is from two to three times that of the horse. Thus, when the time taken in loading and discharging is subtracted the moving time of a motor to be between 2 and 3½ hours per day the motor cannot travel any 60-mile distances. Particularly in rural areas it is difficult to ignore the standing time of a vehicle beyond certain limits as a large portion of this time is dependent upon the customer's convenience.

Comparing motor and horse in this way is undoubtedly, as you suggest, the comparing a marathon runner with sprinters over a hundred yard dash. But because the marathoner was defeated in such a match, who would claim that he was not well developed physically? Both he and the sprinter have their recognized places on the lists of a race.

Just so with the horse, electric and gasoline wagons. A comparison of the three types of vehicles in a given service and under the same operating conditions shows one of the three to be superior. In another service one of the other types might be superior, analysis only can tell. For the services cited in the report of the study by the Massachusetts Institute of Technology the electric truck was found to have advantages in point of cost. The Institute's study intended to supply information by which the cost of performing a given service with each of the three types of vehicles can be compared. It is manifestly impossible to cover all claims of service in a single comparison.

Very respectfully yours,

H. F. THOMSON, Research Associate, Massachusetts Institute of Technology.

Illustrating the Lozier "LIGHT SIX", Six Passenger Coupe model \$4250

**I**N THIS, the sixth successful season of Lozier Sixes, even with Lozier production increased four-fold in its two great plants, there will not be enough Loziers to supply all those who want them. Every prediction made last fall has come true. Every forecast Lozier dealers made has worked out to the letter. Therefore, those who expect to get their Loziers this year will do well to place their bona fide orders now, just as more than fifteen hundred purchasers have already done.

To everyone who knows the automobile industry and the relative regard in which the several high-grade cars are held, there is nothing surprising about the sweeping success of Lozier this year.

For eight years the Lozier has been the only American-built car that has commanded and still commands a price of \$5000.

For six years the Lozier has been the most talked-of six-cylinder car in the world.

Up to the fall of 1911 when, with the winning of the Vanderbilt Cup, Lozier withdrew from racing because it seemed that any further victories could add no higher honors and because the car had been brought to perfection by what racing had taught in years of grilling tests—up to that time every principal honor the American speedway could offer had come to Lozier.

Year after year these victories came because the Lozier was built right. A Lozier was never withdrawn from a race because of mechanical difficulties. Lozier strength, power, endurance and safety have won the respect and admiration of all men who know motor cars.

And the Lozier continues to lead all American cars with no other builders sufficiently endowed with ideas and experience to combat its leadership.

#### LOZIER "LIGHT SIX"

Left side drive, center control—streamline body design, Electric Starting and Lighting System. Touring and Runabout models \$3250. Coupe \$3850. Limousine \$4250.

No wonder, then, that when the Lozier "LIGHT SIX" was introduced for \$3250—was added to the line this year, thousands wanted this car. Thousands who for years have wanted Loziers but did not feel they could afford to pay \$5000 for one.

No wonder that dealers all over the country telegraphed us came to Detroit to secure the Lozier agency. No wonder that our letters in the principal cities received as many as fifty calls and letters in a single day asking them to arrange demonstrations.

The Lozier "LIGHT SIX" has simply swept everything before it in the high grade field. No other car is commonly reported to maintain similar high-grade standards of construction and service offers a six at anywhere near the Lozier "LIGHT SIX" price at \$3250.

The Lozier "BIG SIX" will set a new record in the sale of \$5000 cars—for men who know automobiles and can afford to take advantage of their knowledge are satisfied with nothing less than Lozier quality. And Lozier quality in its entirety—mechanical precision, power, luxury and comfort—is found only in Lozier cars.

Lozier leadership was never so firmly established as it is today.

#### LOZIER "BIG SIX"

Left side drive, center control—electric lighting. Amplest riding system unparalleled fuel economy. Touring models and Roadster \$5300. Limousine and Landaulet \$6300.

## The Punched Card as a Saver of Brain Energy

By H S McCormack

By means of electrical contacts made through holes in thin sheets of brass, the most complicated selections can be artistically rendered upon the piano.

**A**BOUT a half century ago an Englishman named Babbage started work on an invention which is only now nearing completion. He had studied the operation of the Jacquard loom which through the medium of punched cards weaves designs in fabrics. Ideas are punched in the cards to form any design required—no matter how ornate—and the card in turn causes the loom to produce the pattern in many varieties of textiles.

Babbage figured that if punched cards could build designs in textiles there was no reason why they could not be utilized in the same way to make records.

With this idea in mind he built a device which he described as a 'calculating organ.' He induced Parliament to appropriate £25,000 to further his invention. Unfortunately this money was speedily used up in experimental work and Habbage got no further than a crude hand-made and incomplete model of a device he had in mind. Parliament was skeptical and refused to advance more funds, so Habbage was obliged to cease work and the invention was lost to England.

Since Babbage's day the Jacquard principle has been successfully applied to musical instruments, and rolls of punched sheets operate pneumatically the keys of a piano or organ. More recently through the medium of thin sheets of brass in rolls an electrical contact is made through the holes, and the most difficult compositions are rendered upon the piano with the crescendo effects and tempo changes of an accomplished musician.

### How Our Population Is Counted and Tabulated With Punched Cards.

Not many years ago the punched card principle was first applied to statistical work in the United States. Its most prominent use has been in its application to census work. In fact it has always been called the census machine. Formerly the tabulation of population by States, cities, towns and hamlets, the segregation of the masses by native and foreign born male

The facts embodied in this article warrant the predictions made by the author and are worthy of serious consideration. Mr McCormack foresaw present needs by inventing years ago the original typewriter tabulator. He has studied, advocated and applied efficiency by originating and introducing mechanical inventions into accounting and billing and has proved that his insight into these intricate matters has been based not upon theories but fact. The SCIENTIFIC AMERICAN has arranged for several articles from this author, a recognized authority on efficiency as applied to office and executive management. Euton.

The Jacquard loom through the medium of punched cards, weaves designs in fabrics. Holes are punched in the cards to form any design required, no matter how ornate, and the card in turn causes the loom to produce the pattern in many varieties of textiles.

and female white and black, etc., was performed tediously by hundreds of clerks, with the usual percentage of errors and with little opportunity for securing automatic checks such as are to-day so vital in correct analysis. In addition it took about ten years to complete the work. Now it takes ten months.

After the Government found this machine no successful in its work, it was adapted to cost accounting and has been used extensively by large firms. Inventors of business appliances began to see that the punched card principle was capable of infinite adaptation and could

perform operations which were previously considered impossible for a mechanical agency to execute

An interesting example is the automatic typewriter which actually takes the place of the human fingers for making duplicate letters.

### The Player-piano Principle Applied to the Typewriter

The writer a few years ago journeyed to Detroit, Mich., and inspected a hand made model of an automatic typewriter operator. Here was employed the same principle as that of the typewriter, but was adapted to turn out form letters actually typewritten. At the time of the examination the hand made model was a very crude affair and the "soot box" variety but the principle was sound and the development of a commercial possibility. One of the leading manufacturers has taken the device under his control, and developed it to a point of practical usefulness. It is almost identical with the typewriter, but the use act as an evolution of the crude hand made model produced by the inventor.

The device to-day is supplied with a quantity of retimed type, the electrical energy returned on through the application of the pneumatic principle the machine automatically picks up a letterhead and places it in the carriage of the typewriter. The carriage is then moved forward, the line and the typewriter begins to operate as though actually under the impulse of human hands and fingers. The typewriter carriage moves to the right and the same, the carriage is moved back to the left, placed on the left of the letterhead.

Moving from space to space—the keys being depressed and the type bars flying up and down—there is something almost uncanny in the operation of the typewriter as it proceeds step by step to turn out a complete typewritten letter. The completed letter is removed automatically, with no human hands near, and another letter is started. The name address and salutation are automatically changed and the operation repeated, letter after letter, until the machine automatically stops. Approximately four hundred duplicate business letters a day can be typewritten by this machine.

The automatic typewriter takes the place of human fingers. It uses a punched roll of paper like a player-piano. By the application of the pneumatic principle the mechanism operates as though actually under the impulse of human hands and fingers.

Some day we will have a ledger cabinet, showing debit and credit dials, operated by cards. Clerks will be supplied with cards already punched with their own number, also the number of their department. When a sale is made they will punch and not write the amount as they do now.

Now comes what seems the most wonderful application of the punched card principle—that of mechanical bookkeeping and business recording—almost replacing the human brain in its performance, and indeed outdistancing it in accuracy. Through a prearranged plan, four business men recently met one a railroad official from a distant city, answered an official connected with one of the country's leading industrial corporations, the third an official of the greatest textile company, while the fourth was the president of a concern of international reputation.

These men were brought together for the purpose of considering at a private demonstration a mechanical marvel which was the result of years of study, hardship and ingenuity on the part of an inventor assisted by mechanical experts whose experience qualified them to carry out the plans of the inventor. The result of years of painstaking effort, trials and disappointments, costly experiments and the expenditure of thousands of dollars could all be shown in a few moments. A few minutes demonstration does not, in this particular case, do justice to the men, who were authorities in their fields, understood all they saw. What they beheld in actual operation was almost incredible. Although they were prevented in advance to see certain results accomplished, they did not stray in their minds from the definite principle that will radically affect methods of mechanical accounting.

When these men met at the appointed hour and place, a waiting taxicab whirled them to a section of the west side of New York, which was totally unfamiliar to them. Arriving before a large loft building, the guide led the little party to a machine which seemed placed what was heretofore possible only by human intelligence.

That machine performed the remarkable feat of recording approximately eleven entries of a single transaction—eleven entries which would ordinarily have to be made with a pen with eleven chances of making a mistake. In recording the amount is entered upon a sales check, to be entered upon a bill, again upon the segregated sales record, again into the sales ledger, through another operation placed to the credit of the sales person, then to some department in addition to a record as to whether the package was delivered by mail, carried away or sent by regular delivery or express. Instead of this constant juggling with the same figures through a mass of operations there will be an original entry upon a punched card and this card will, through the medium of motor-driven machines, be automatically sorted into various divisions and subdivisions, and recorded item by item upon counters or wheel sets into adding mechanisms.

#### Prediction of the Mechanical Ledger

The ledger cards for the A and H industry will be placed into a machine, the current will be turned on and with the sales checks in the magazine the machine will pick out the ledger card of Adam Aaron and from the magazine pick out the sales check of Mrs. Aaron and will debit the account with \$15.75, and at the same time add the amount into the total register. After the ledger postings are complete, the sales checks will be passed through the machine again and listed according to departments. When the department totals are secured, the sales checks will be sorted and listed according to sales persons. At the completion of each morning, the machine will automatically throw a lever and start the printing mechanism, which will deliver to the operator a printed adding machine list showing the items according to the desired regulations.

As the checks are received in payment or part payment of accounts, the entry will be punched upon a card, the ledger sheets will again be returned to the machine and in red upon the ledger sheets will be printed the credits. Automatically the amount paid on account will be subtracted from the debit, and the balance, or amount remaining unpaid, will also be printed upon the ledger sheet.

The same principle will be applied to pay rolls, in other words, the laborious accounting of to-day, the repeated juggling of the same figures into the various combinations necessary to analyze business satisfactorily, is to become a thing of the past.

If firms could estimate half of the expenses in their accounting departments, losses would be turned into profits and companies who have never paid a dividend, and those who have failed to pay ordinary dividends, would immediately be cleared, among the successful dividend-paying companies.

An understanding of the principles described will convey to the reader something of what these four men saw in operation. They saw entries of sales placed upon cards half the size of an ordinary playing-card. They saw when the entries were typed that under

By means of such cards the United States Census Bureau tabulates the population by States, cities, towns and hamlets. The work, once performed in years by hundreds of clerks, with many errors, is now performed in ten months.

neath the figures were small round holes. The number of the department, customer's number, clerk's number, amount of sale, and other details according to requirements, were entered upon these small cards. A thousand cards were placed into the magazine of the machine and the current turned on. The machine itself was one hundred adding machines worked into an integral whole. A part of the mechanism was on him

A machine in use by the Census Bureau.

dred wheel sets, upon which were being accumulated the lever was raised and automatically a printed strip appeared which was identical in appearance with the printed strip secured from a listing adding machine. The printed strip gave the results of departments 1, 2, 3, etc., up to 100, and opposite each

When the machine finished sorting all the cards a lever was raised and automatically a printed strip appeared which was identical in appearance with the printed strip secured from a listing adding machine. The printed strip gave the results of departments 1, 2, 3, etc., up to 100, and opposite each

The punched card principle applied to the keeping of a mechanic's account. This card has only to be run through a machine in order to obtain a printed statement of the year's output, time, and wage.

department was set down the amount sold. Then, as a grand total, the machinery clicked, a number of letters arose and there was printed one grand total showing all accounts which had been segregated to the various departments, all grouped into one grand total.

#### A Further Application of the Jacquard Principle

There is possible a still further application of the Jacquard principle and its inventors will no doubt get to work to apply the same principle to addressing machines. An ordinary card index will be used. The name of John Jones, 281 Broad Street, New York City, will be written upon a 3 by 5 card while underneath the name and address will appear numerous perforations. The cards will be very inexpensive and can be utilized for follow up or for regular customers per roll one and no expensive machinery will be needed to make up new cards.

There is nothing but common sense in all this. To illustrate: Some four thousand years ago, a method of laying bricks came into practice, and this same method was handed down from generation to generation until very recently. Now, a discovery of Frederick Taylor—Gilbreth—has changed the general order of things and reduced the number of wasted operations until today a bricklayer with less effort can lay double the number of bricks. Gilbreth did not discover any new principle. He simply applied common sense to a well known principle and applied it to masonry and bricks instead of tools and steel.

In almost every business house in the country some parallel case can be brought to light by an efficient engineer in making his examination. It is common to find a business firm applying efficiency to the order requisition and billing which totally ignores the same principles which could be applied to their voucher system with equal results in saving of time and expense. On the other hand, a department store with appliances and systems of various kinds will retain in its purchasing department an antiquated method for requisitions simply through failing to see that the same idea used so effectively in other departments are really a principle which, when combined with a little common sense go far toward reducing friction and promoting efficiency.

#### The Pneumatic Typewriter

Now an inventor is working upon a principle where phonetic sounds can be recorded upon strips of paper. A man for example will call in his stenographer who will have this small device instead of the old fashioned note book and pencil. The little device will be a pneumatic writer which punches letters in a strip of paper. These strips of paper will be fed into an automatic typewriter which will typewrite the words as the punchings in the strip will bring into play certain cards which will allow the machine to write the proper combination of letters.

Thirty years ago business houses had copyists who laboriously wrote pen written letters, but to-day the stenographer fills the place. Twenty years from now bookkeepers, as they are known to-day, will be as great a curiosity as copyists are. In their place will be clerks of known ability and accountants who will take the machine-produced figures, and through the medium of graphic charts will present to the heads of departments a record of the previous day's business with comparative records in which, month after month and year after year, by ten o'clock each morning the record sheets dealing with vital totals will be placed upon the desks of the officials, who will then be in a position to keep their fingers upon the pulse of the business at all times.

There was a time only fifty years ago, when a large majority of small businesses were run on the cash drawer and hit-or-miss principle. Conditions improved.

The business men wanted a balance struck off at the end of the year. It was followed by the semi-annual inventory after which the more progressive wanted a balance sheet every month. Finally came the weekly report while in some offices the daily report has arrived. But with increased competition improved machinery and a reduction in overhead expenses, and through the introduction of efficiency the average business man, instead of delving into ancient history, a month old, will be able, after reading the latest quotations in the morning paper, to pick up his own balance sheet and know the latest quotation that his business has placed upon his ability.

With mechanical ledgers somewhat resembling telephone switchboards, bank checks will punch cards as deposits are received or withdrawn.

### Tests of German Aeronaftic Motors

ON the festive representative German aeronaftic motors which were entered in the competition for the 50,000 mark prize offered by the Kaiser for the motor which should make the best showing in a series of tests conducted by the German government which competition was held on the Kaiser's birthday, January 27th, 1911, but which is noted through the series of tests. Of the nine tests the best showing was made by the Benz motor a four-cylinder crankshaft rated at 100 horse-power designed by Chief Engineer Benz and it was awarded with a tally of 50 points amounting 170 which were chalked up for its performance against the nearest competitor. The other four prizes offered 20,000 marks by the character of 10,000 marks by the minister of war and prize money each by the secretary of the navy and the secretary of the interior were awarded to the makers of the 100 horse-power Daimler 105 horse-power N. A. G. 72 horse-power Daimler and 70 horse-power Napier respectively. The scores of these four contestants were 170, 162, 140 and 120 points respectively.

The conditions imposed and the tests to which the motors were subjected were calculated to compare the motors with regard to the total amount of fuel for the work at hand and to the total cost of the conditions was that the motor must be assembled on the spot within a time limit of three days, one of the tests necessitated that the motor be sufficiently light to permit the plan in which it was mounted to consist of a light with the motor and the engine and the engine after the plan had been chosen for an equal interval the churning plan being fifteen per cent. In full the tests were. After erection within the three-day time limit the motors were subjected to a half-hour test run, followed by a full hour test run, the clock mounted in an aeroplane the motor was run under full load for fifteen minutes and the plan guided so that it mounted a fifteen per cent grade the motor then was stopped and the plan guided to earth it being necessary for it to glide for fifteen minutes.

The motor then was run for seven hours without stopping. The plan was then driven in horizontal flight for three hours, and after a stop of not half an hour an other two and one half hour flight was included in the test.

The final test consisted in running the motor at top speed for half an hour.

The prize winning motor was possessed of four cylinders each of 100 mm. with overhead valves, bore and stroke were 130 and 180 millimeters, respectively and the power developed was, as before stated 100 horse-power at 1,200 revolutions a minute. When speeded up to the crankshaft speed was 1,280 revolutions a minute, the power was correspondingly greater. In the design of the motor no effort was spared to obtain reliability, as is evidenced by the duplication not only of the ignition system (two separate and distinct magneto's operating on separate plugs positioned on opposite sides of the cylinder's combustion) but of the water circulating pump and the oil circulating pump as well.

By way of reducing the weight to the very last degree the cylinders are furnished of a special iron alloy more easily worked than steel and at the same time more durable under the conditions. The cylinder jackets are of pressed steel and are seated into place.

During the tests the gasoline consumption was but 210 grams per horse-power hour considerably less than that required for the operation of the average automobile motor. This showing is due in part to the arrangement of the intake manifold which is triple branched and innocent of sharp bends calculated to reduce banking of the mixture and in part to the peculiar construction and location of the exhaustor. The latter or at least the larger portion of the latter is cast integral with the crankcase so that it is in reality a part of the motor and not an appendage. The location has much in its favor since it not only economizes front and permits of a very compact construction but also eliminates projecting parts to a greater or lesser degree and provides a support for what would otherwise be a free end of the manifold found in the ordinary situation and location of the manifold. Moreover, as the air inlet leads from the inside of the crankcase the air supplied is heated so that a more homogeneous mixture is obtained. Air is admitted to the crank chamber through a valve provided with a projectile screen.

Circulation of the cooling water is induced by a gear driven propellered centrifugal pump driven from the crankshaft. A second pump of similar construction is provided for emergency use and is driven by means of two gears from the main gear shaft. Careful balancing of all of the component parts, both statically and dynamically has resulted in the production of a motor which is singularly free from vibration at all speeds. The weight of the motor including all piping and fittings is but 150 kilograms.

### Wind-rolled Snowballs

ONE of the strongest gusts of wind and snow was witnessed by residents of Danvers, Washington the afternoon of January 17th, when a strong gust of wind from the southeast blowing for a period of a minute and a half rolled thousands of snowballs from a particle of snow to big ones as large as ordinary barrels and resembling in every respect huge rolls of cotton batting. A peculiarity of the unheard of prank of nature was the fact that nearly all the rolling was up hill every smooth slope for miles being covered with the balls. An inch of snow of the right consistency

A group of snowballs rolled by the wind.

and fallen on a hard crust of snow and made possible this peculiar phenomenon. The photographs and their brief description were supplied by Edward H. Page of Danvers, Washington.

By an odd coincidence a similar freak has just been reported to the Editor by T. J. Moon of Middletown, N. Y. He writes:

"At the town of Potsdam, N. Y., on the 20th of last December occurred a light but very sticky fall of snow accompanied by a light wind which blew at right angles to the crest of a slight hill on the lee side of which were found the snowballs which are seen

View showing the concave ends of the balls.

in the pictures. The wind had evidently picked up a wisp of snow rolled it along as a boy does, to make a snow man, and as they rolled, the size of some reached a diameter of over two feet, the concentric layers of added snow could be easily seen, in fact they show in the print of one taken at close range also the trail left as the snow picked up, is plainly visible. There were over fifty of these wind rolled snowballs in our yard alone and a few near by where conditions were similar, but in all the experience of the 'oldest inhabitant'.

A nearer view of one of the balls.

no such peculiar occurrence had transpired before, and I have never heard of the like, so thought it might be of interest. A peculiar fact was that the rolls of snow were concave at the ends, like the vertices of a fish, showing the size of the small bit of snow first picked up at the crest of the hill, and indicating that the increase had been in length as well as diameter."

### A New Way of Staying Soils

NO industry is so vital to the well-being of a nation as agriculture, and nothing is so vital to agriculture as the soil. From its treasury it has been estimated that we drew during the year 1909 more than \$4,000,000,000, and its possibilities are as yet only partially realized. There are still in this country millions of acres which have never felt the plow, while those which are now under cultivation, by the application of scientific principles, he made to produce many times the present value of their

products. How to use and not abuse this great resource is the most important problem which faces the farmer of to-day—no worthy of the best efforts of our most profound and learned scientists, for upon its solution depends the future prosperity of the nation."

This statement from Bulletin 85 of the Bureau of Soils relating to the soils of the country. While a comparatively small percentage of the soils of the United States have been surveyed and analyzed by the department, more than 400 types of soils have been discovered during the progress of the soil survey. The existence of such a large variety of soil types, each possessed of definite and peculiar characteristics, calls attention to the importance of a careful study of the soils and their relation to agriculture. The Bulletin says:

"The old idea of soil investigation was to collect samples, examine them in the laboratory, and see what differences could there be determined, the newer idea is to study the characteristics and properties of soils in the field, classify them according to obvious differences, and, with this information in hand, use the laboratory as a means of ascertaining the cause of such variations as cannot be determined in the field. This method of attacking soil problems is the reverse of the usual practice, but because of the great difficulty in duplicating field conditions, it is believed that a field examination should precede laboratory studies. The field observations can thus be used as a check upon laboratory investigations, and as an aid in their interpretation. Field studies furnish a safe and necessary anchor with which to keep the laboratory experimenter from being dashed against the rock of pure speculation. The classifying and mapping of the various soil types, together with the former, is the condition of the soil, their origin, formation and best treatment for agricultural purposes, the great difference between the many types, and adds

Since the soil varies so much as regards both its inorganic and organic constituents, marked differences in character must necessarily result from the almost infinite number of combinations which may be found. All these differences, however, may be traced to two main factors. First, the character of the rock or material from which the soil has been derived, and second, the processes or agencies by means of which this material has been changed from mere rock or rock debris into a medium suitable for the growth of plants. The former is the soil-forming agencies, the latter with soil-forming agencies. To these two groups of factors are to be attributed the numerous variations in soil conditions found over various parts of the earth.

"The importance of distinguishing between these two groups of factors cannot be too strongly emphasized. The tendency in the past has been to stress the former to the neglect of the latter and this has resulted in classifying together soils of very dissimilar character, simply because they were derived from the same rocks or from rocks which have been formed in the same manner."

### The Current Supplement

IN the issue of the SCIENTIFIC AMERICAN SUPPLEMENT Prof. W. E. Flammarion speaks in the highest terms of the valuable contributions to knowledge which have been made by amateur astronomers.—Prof. July is a most interesting article, tells us how novel and primitive material have in the course of long geological ages produced the rocks which we find them, by the emission of disintegration products. These halos are of perfectly definite dimensions, and display many remarkable features. They have, moreover, a definite location in the most question of the age of the earth.—James Pattison, in an illustrated article, tells us of the life boys and light ships of New York harbor.—Dr. Ferranti, in delivering his James Watt lecture on the subject of Prime Movers, made some remarkable comments on the scope and limitations of the Diesel engine. This lecture is reproduced in the rent issue.—Within easy access from New York city some remarkable features of the new water supply system are being worked out at the Kensico reservoir. These are described in an illustrated article. Dr. H. de Andrade reports on the latest vacuum pump, which far exceed earlier forms in the low pressure attainable.—Dr. H. R. Hottelworth writes on Experimental Pyrology in its relation to medicine.

Olive Bridge dam Esopus Creek flowing through temporary tunnel.

Building Olive Bridge dam to form the Ashokan reservoir

## Creating a Subterranean River Ninety Miles in Length

How Catskill Water is Being Brought to New York

### Phenomenal Growth of New York.

**G**REATER NEW YORK is adding to its population at the rate of 140,000 people per year—an increase which is absolutely without precedent or parallel in the growth of the world's great cities. Such an increase as this creates enormous difficulties in the problems of housing, food supply, transportation and proper hygiene. For many years past and long before the rate of increase had reached its present proportions, the city authorities have been at their wits' end in endeavoring to enlarge the various facilities of the city so as to keep pace with the demands of its ever-growing population.

### The Peril of Water Famine.

With the exception of rapid transit there is no problem of the city's need which has proved more serious than providing or more difficult, at least in recent years than that of providing an adequate supply of pure drinking water. At frequent intervals the city has been threatened by that justly dreaded terror, a water famine—justly dreaded because so obvious to any thinking of a total failure of water might mean an outbreak of pestilence, to say nothing of the loss and incalculable occasioned by the shutting down of the various factories and smaller industries which a shortage of the water supply would necessitate.

It is not so very many months since the whole city was watching with a very anxious eye the steady fall of the water levels in the various reservoirs of the Croton watershed for a season of drought extending far into the winter and served to bring the billion remote well close to its very doors.

In view of the rapid growth of the city it was evident at the outset that any adequate scheme for increasing the water supply must be made upon the broadest possible basis and that it should make provision not only for the immediate needs of the city but for those of many a decade to come. This has been done by the Board of Water Supply, and it is the purpose of this and the following article to show that the project of bringing the Catskill Mountain water to New York has been considered on such adequately comprehensive lines that the possibility of any shortage of water in this great city has been removed into the very far future.

On May 11th, 1906, the State Water Supply Commission approved of the application of the Board of Water Supply of this city for obtaining a daily supply of 500,000,000 gallons of water from the Esopus Reservoir, Schoharie and Catskill creeks in the Catskill Mountains, at an estimated cost of \$161,807,000. In 1910 a plan for the distribution of the water throughout Manhattan (Queens and the Bronx) by a deep pressure tunnel was

In the Hudson River siphon, 1,100 feet below the river

Placing the nine and one half foot steel pipe—Fondry Brook siphon.

approved by the Board of Estimate and Apportionment. The additional cost of this scheme is \$14,000,000.

### The New Scheme of Water Supply.

The new supply of water, of the finest mountain quality is to be taken from four watersheds, having a total area of nearly nine hundred square miles. The total estimated capacity of these four gathering grounds is even in a series of unusually dry years, equal to supplying 770,000,000 gallons daily. Reservoirs will be built as they are required, in each of these basins, and they will be connected by aqueducts. For the present, the Esopus watershed only is being developed in a series of dry years this watershed can furnish a daily supply of only 250,000,000 gallons, but the aqueduct leading to the city is being built of double that capacity or 500,000,000 gallons daily. The first contract for construction of the Ashokan reservoir in the Esopus watershed to Croton Lake. By the end of 1908, 22 per cent was done, 60 per cent at the close of 1910, 78 per cent by 1911 and at the present time about 96 per cent of the work is done. The delivery of water into the Croton reservoir, which will be possible this year, will prevent any possibility of water famine during the completion of the new aqueduct to New York.

The system under construction and now nearing completion consists of a large reservoir in the Esopus basin an underground aqueduct seventeen feet in diameter by which the water is led for sixty-four miles to another large basin, the Kensico reservoir, which will serve for emergency storage, a third reservoir situated about fifteen miles south of Kensico and just over the New York city line, known as the Hill View reservoir, which will equalize the difference between the use of water in the city, which, of course, varies from hour to hour and from day to day, and the steady flow coming in from the aqueduct. Between Hill View and the city the system consists of a deep circular, high-pressure tunnel, through which the water will be led beneath Manhattan, to be distributed by surface mains throughout that city, and also throughout the other districts of Greater New York.

### The Ashokan Reservoir.

The great Ashokan reservoir is situated about fourteen miles west of Kingston on the Hudson River. Its cost is \$18,000,000, and it will hold sufficient water to cover the whole of Manhattan Island to a depth of twenty-eight feet. The water is impounded by the Olive Bridge dam, which is built across Esopus Creek, and also by the Beaver Kill and the Hurley dams, which have been built across streams and gaps lying between the hills which surround the reservoir.

The Olive Bridge dam, 4,654 feet long, 220 feet high.

Diamond drill boring horizontal hole 1,100 feet below Hudson River

voir. By the first of January, this year 71 per cent of this work was done. The dam is a masonry structure 100 feet in thickness at the base and 23 feet thick at the top. The surface of the water when the reservoir is full is 300 feet above tide level. The total length of the main dam is 4,654 feet, and the maximum depth of the water is 190 feet. The area of the water surface is 124 square miles, and in repairing the bottom it was necessary to remove seven villages, with a total population of 2,000. Forty miles of high way and ten bridges had to be built. In the construction of the dam and dike it was necessary to excavate nearly 8,000,000 cubic yards of material and 8,000,000 cubic yards of embankment and nearly 1,000,000 cubic yards of masonry had to be put in place. The maximum number of men employed on the job was 3,000.

#### The Ninety-two Mile Aqueduct

The water is conducted from Ashokan reservoir as a huge, underground, artificial river. The aqueduct is ninety-two miles in length from Ashokan to the northern city line, and it should be explained that it is built on a gentle grade, and that the water flows through this at a slow and fairly constant speed. The aqueduct contains four distinct types: the cut-and-cover, the grade tunnel, the pressure tunnel, and the steel pipe siphon. The cut and cover type, which is used on fifty-five miles of the aqueduct, is of a horseshoe shape and measures seventeen feet high by seventeen feet six inches wide, inside measurements. It is built of concrete and on completion it is covered in with an earth embankment. This type is used wherever the nature of the ground and the elevation allow. Where the aqueduct intersects hills or mountainous, it is driven through them in tunnel at the standard grade. There are twenty-four of these tunnels, aggregating forty-four miles in length. They are horseshoe in shape, seventeen feet high by thirteen feet four inches wide and they are lined with concrete. When the line of the aqueduct encountered deep and broad valleys, they were crossed by two methods. If suitable rock were present, circular tunnels were driven deep within this rock and lined with concrete. There are seven of these pressure tunnels of a total length of seventeen miles. Their internal diameter is fourteen feet, and at each end of each tunnel a vertical shaft connects the tunnel with the grade tunnel above. If the bottom of the valley did not offer suitable rock for a rock tunnel, or if there were other prohibitive reasons, steel siphons were used. These are nine feet and eleven feet in diameter. They are lined with two inches of cement mortar and are imbedded in concrete and covered with an earth embankment. There are fourteen of these pipe siphons in a total length of six miles. At present one pipe siphon to carry the water 1,111 miles three will be required for each siphon.

Of the many siphons constructed, by far the most interesting and difficult is that which has been completed beneath the Hudson River. The preliminary bor-

This section consists of a steel pipe, lined internally with two inches of cement mortar, and imbedded in reinforced concrete.

ings made from some in the river showed that great depths would have to be reached before rock sufficiently solid and free from seams was encountered to withstand the enormous hydraulic pressure of the water in the tunnel. After failing to reach rock in the new drills two series of inclined borings were made from each shore one pair intersecting at about nine hundred feet depth and the other at about fifteen hundred feet. Both showed satisfactory rock and according to a shaft was sunk on each shore to a depth of approximately eleven hundred feet, and then a horizontal tunnel was driven connecting the two. It is of interest to note that because of the enormous load which must be measured from the flow line far above the river surface the pressure in the horizontal tunnel reaches over forty tons per square foot.

#### Kenadese Reservoir

Next to Ashokan the most important basin is the Kenadese reservoir, which lies east of the Hudson and is situated thirty miles north of the City Hall. It will hold sufficient of the Catskill water to supply the city for several months. Its purpose is to act as an emergency storage reservoir so that if it is necessary on account of accident to interrupt the flow in the seventy-seven miles of aqueduct between Kenadese and Ashokan this can be done without interrupting the city supply. The cost of this work is \$8,500,000.

The reservoir will be formed by a huge masonry dam across the valley of the Bronx River. The surface of the water will be at an elevation of three hundred and fifty-five feet above mean sea level and will cover 2,218 acres. It will contain when full about 10,000,000,000 gallons, of which 2,000,000,000 gallons or sixty days continuous supply at 500,000,000 gallons daily will be available. The main dam will be thirteen hundred and forty-three feet long. The total height will be three hundred feet. It will be two hundred and thirty feet thick at the base and twenty-eight feet thick at the top. The average depth of the reservoir will be one hundred feet and its maximum depth at the wall of the dam will be one hundred and fifty-five feet. An interesting feature of the construction is that the entire dam will be divided into sections by transverse expansion joints, which will be placed about thirty feet apart longitudinally. On one side this will be faced with concrete blocks forming a series of vertical tongues and grooves method which the masonry of the other side will be built. Near the upstream face will be a copper strip which will cover the expansion joints and act as a water stop the strips continuing from the bottom to the top of the dam. In order to catch any water that may seep through from the upstream side diagonal walls will be built fifteen feet apart measured longitudinally. They will be formed of porous concrete blocks. They will reach from the top of the dam to a longitudinal inspection gallery at about the level of the reservoir bottom, which will in its turn be connected with a transverse drainage gallery,

which will lead to the downstream base of the dam. This will prevent any seepage entirely through the wall and will avoid that discoloration which is liable to mar the architectural beauty of structures of this kind.

#### Aeration and Filtration.

Both at the Ashokan and Kenosha reservoirs aeration will be built, each of which will be capable of raising and treating all the water which will flow in the aqueduct. The aerator is a large reel angular basin five hundred feet by two hundred and fifty feet, containing about eighteen hundred nozzles, through which jets of water will be thrown into the air. The nozzles will be of such form that the water will be divided into a fine spray and this will permit of a thorough admixture of the oxygen of the air and the removal of gases and matters which would cause taste and odor. For the present no provision will be made for filtering the Catskill water but provision has been made for a filtration plant by the purchase of three hundred and fifty acres of land near Tarrytown, adjacent to the aqueduct.

#### Hill View Reservoir

From Kenosha the water will flow to the Hill View reservoir which will serve to equalize the difference between the amount of water used in the city and the amount of water flowing in the aqueduct. Also it will furnish a great quantity of water should there be an unusual demand such as occurs during a great conflagration. Its capacity will be 600,000,000 gallons. The reservoir is divided into two basins so that one may be used while the other is being inspected for repairs. The aqueduct is carried within the wall which divides the two basins, and the aqueduct water can be raised through the reservoir and delivered directly into the city tunnel.

Our thanks are due to Mr. Alfred D. Plan, Department Engineer of the Board of Water Supply for courteous extended during the preparation of this article.

#### The International Building Exposition in Leipzig

AN International Building Exposition will be held in Leipzig this year. The time during which applications for space may be submitted has recently been extended until the end of February. In order to permit firms which have not yet submitted applications to make good this omission. Space to the value of more than a quarter of a million dollars has already been allotted and the demand is still brisk.

Dr. Probst of Berlin whom the director sent to this country to arouse American interest in the exposition and to secure adequate participation therein by the United States Government cities, associations, industrial firms, etc. have de-

scribed his travels in a lecture, delivered in Leipzig, of which the following is an abstract.

The United States Government shows much interest

in the exposition. The cities of New York, Chicago, Philadelphia, and San Francisco, the American Bridge Company (the oldest and greatest of American bridge-building firms), and the Canadian Railway Company will exhibit typical models and photographs of "skyscrapers," bridges, city views, schools, waterworks, etc. Very complete problems are presented to American and users by peculiar geological, climatic and traffic conditions. The exhibition will show how these problems are solved in the eastern, central, and western States.

Both the rapidity and the methods and materials of American building are greatly influenced by the exceedingly high rate of wages (\$2 or \$3 per day) and by the almost total absence of legal building restrictions. The high cost of labor has led to the substitution of machine work for hand work as far as possible. The lack of deficiency of building laws in many places has permitted speculative builders to erect unsafe structures. A striking instance of this was revealed after the earthquake in San Francisco where foundations of many of the fallen buildings were found to have been constructed in the most reckless manner. First-classworthy energy was then displayed in the erection of a new city which may be regarded as structurally unexceptionable. Examples of the new buildings of this beautiful city will be represented at the Leipzig exposition.

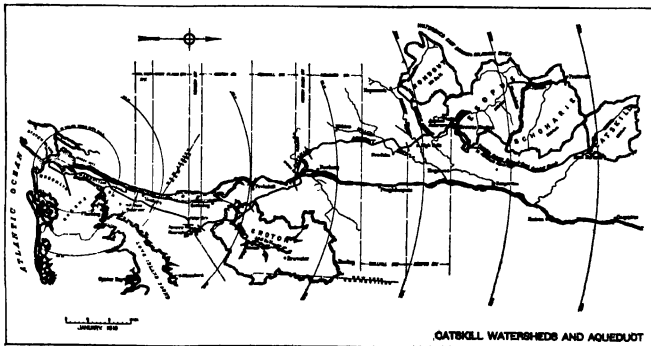

Almost everywhere in America Dr. Probst noted with approval a sharp demarcation between business sections and residential sections, which does not exist in Europe outside of England, but he was unfavorably impressed by the lawless co-mingling of ordinary four-story and five-story buildings with towering structures of thirty or more stories. American engineering societies, however, are beginning to give attention to aesthetics and by strict considerations they have hitherto been ignored and many of their members will visit the Leipzig exposition where these matters will be fully illustrated.

Dr. Probst finds ferro-concrete the building material most extensively used in America, and mentions an ingenious device employed in the construction of most large buildings and consisting of a central tower from which the concrete flows through a movable spout to any spot where it is wanted.

The project of Chicago ship canal will be well represented at Leipzig. Dr. Probst regards Canada with its great fertility and scenic beauty as the land of the future and the most promising field of activity for the building engineer. In conclusion Dr. Probst named, as the two most eminent American building engineers, Lindenthal and Hornbush, both of whom will exhibit models of their works at the coming Leipzig Building Exposition.

## Supplying a Metropolis With Mountain Water

How Mining Operations Are Being Carried on Through the Heart of New York

THE preceding pages tell how the new aqueduct is being constructed from the Catskill Mountains down to the New York city line, where, at the Hill View reservoir the waters will pause before taking their plunge into the heart of the city.

The problem of admitting so large a flood into the metropolis is no small one, particularly when the chief demand for the water will come from those sections of Greater New York which lie many miles away. For the present at least little if any of the Catskill water will be used in Manhattan and the Bronx but most of it will be consumed by the boroughs of Brooklyn, Queens, and Richmond. The Water Waste Campaign which has been carried on for the past few years has so far reduced the consumption of water that the Croton system, which can furnish steadily 250,000,000 gallons of water per day, can easily take care of the immediate wants of Manhattan and the Bronx as well as the demand from these two boroughs for many years to come. It is not likely that the population in Manhattan will increase much unless it undergoes a marked vertical growth for now there are practically no more vacant lots to be built upon so that in estimating the future demands upon the Croton system we must consider chiefly the growth of population in the Bronx. In the other three boroughs of the city however there is a present demand for water and the probability of large increases in population in coming years.

To conduct the Catskill water into Brooklyn and Queens, it was decided to build a trunk line, so far beneath the surface that there would always be 150 feet of good solid rock for the roof of the tunnel, and provide a course for a subterranean river which could be tapped as needed for the city's supply, and which, at the same time, would be so completely buried that it would never menace the safety of structures above it. When this tunnel is completed it will be one of the most durable pieces of work ever constructed by man for practically nothing but an earthquake can destroy it and even this possibility is very remote, for the rock underlying New York is of very early formation and not at all liable to seismic disturbances. And so the city tunnel of the Catskill aqueduct is being bored through the rock on the average of 200 to 250 feet below the surface except in places where the nature of the rock is of such a character as to call for a much greater depth.

The first dip takes place just above the Harlem River, where the tunnel drops down 302 feet below the ground level. Then it runs practically horizontally until it passes the dip in the rock under 120th Street. Thence it rises again and maintains a practically constant level of 350 feet under the city, until it arrives at the ancient bed of the East River. A glance at the map of New York city will show that the East River makes a decided turn about the lower east side or "heel" of Manhattan. In pre-historic times, the East River had no elbow in its course, but ran directly across the head of Manhattan, and it was away from the rock at its bed to considerable depths. However, the

large deposits of earth and rock carried by the glaciers caused the river to be pushed eastward out of its normal channel and over the solid rock bed. When

borings were made for the aqueduct through this section of the city it was found necessary to lay it at a depth of about 750 feet below the surface. As indicated in the accompanying drawing,

much of the rock through this section is composed of sandstone and is comparatively very shallow. Seven hundred and fifty feet is an enormous depth, second only to the great shafts under the Hudson River which is 1114 feet below the river surface. It so happens that the deepest shaft ever sunk in New York city equals the height of the tallest building in the world. To illustrate this enormous

depth, our artist has taken the Elvira Building, the Woodworth Building towers turn, that is from the ground down at the Clinton Street shaft at the west bank of the East River. Enormous as is the building yet it barely reaches the aqueduct at this point. Evidently there will be plenty of clear room over the tunnel, and yet it is worth noting the aqueduct follows the street lines so as not to trespass on private property.

Arrived in Brooklyn the aqueduct rises again to within two or three hundred feet of the surface and is pushed as far as it is possible to carry it in solid rock and yet commensurate with the surface. This shaft was found to be at the junction of Fourth and Third avenues. Here it was necessary to go through 215 feet of overlying earth before coming to the rock. The caisson sunk over 100 feet below the water line before rock was reached. A considerable difficulty was here experienced in sinking the shaft to the rock because it relied for the use of pneumatic pressure that taxed the endurance of the workmen to the limit. From here on the water will be conducted through pipes laid in a trench of a moderate depth below the surface. From the foot of Seventh Street Bay Bridge the conduit will be run across the Narrows to Staten Island through a pipe 40 inches in diameter provided with flexible joints and laid in a submarine trench. The details of this section of the work have not yet been given out. However tests have been made to discover at what depth the pipe line under the water must be buried. It is evident that it must be far enough below ground to prevent its being entangled with anchors from large vessels that may have to anchor in the Narrows. The matter has been thoroughly investigated and practical tests have been made by dragging anchors of large size along the bottom. It has been determined that if the pipe line is buried at least eight feet under the bed it will be entirely safe. On the Staten Island side a 36-inch pipe will carry the water on up the hill and through a tunnel into Silver Lake reservoir 120 miles from the source in the Catskills.

The greatest interest in this city section of the aqueduct attaches naturally to that part which is being excavated through solid rock under the busy city. It is a surprising fact that a work of such magnitude can

The height of the Woolworth Building equals the depth of the deepest aqueduct shaft in New York.

"Holed through" from shaft 16 to shaft 17. Dangerous rock overhead due to vertical seams.

Permanent channel iron support for a treacherous roof. The beams will be imbedded in the concrete lining.

be carried on directly under our feet without even venturing, as in the last. The only surface evidence of the deep rock tunneling is to be found at the various shafts which are located in parks or public squares. The principal difficulty that presented itself at first was the question of storing explosives for a work of such great proportions. To keep the necessary explosives on the surface was to harbor constant menace to the lives of the citizens. The matter was finally solved by placing the dynamite magazines far under the surface in the rock and setting the doors to these magazines so they will automatically close in case of an explosion and trap the hot and poisonous fumes in the rock chamber where they can do no harm to the workmen. The idea was borrowed from European practice where mining operations are conducted close to and sometimes directly under large cities. Access to the dynamite chamber is had through a zigzag drift. At each turn of the drift a pocket is excavated, and the chamber itself is made of large capacity. In this chamber the dynamite is stored under a protecting roof to keep off any fragments of rocks that might fall when jarred in the shooting in the tunnel. At the entrance of the drift a very substantial concrete bulkhead is built and in this is a low doorway. The door is of massive construction built of 16 beams sixteen inches deep and spaced apart with oak beams twelve inches square. The door has beveled edges, so that it will seat itself snugly in the doorway. The door is always kept open at an angle of about 15 degrees. In the magazine a thousand pounds of dynamite may be kept at a time. Should this be exploded, the explosion wave would have to travel down the zigzag passage and would lose much of its force at each abrupt turn finally striking the door with greatly diminished impact. The door would be shinned split to the head of air leading from the drift and would then be held shut by the gases of the exploded dynamite. A magazine of this sort has been constructed near the foot of each shaft; not at the foot, however, for fear that in case of a mishap it might block the escape of the men. The magazines have been tested by exploding a number of sticks of dynamite around the first level in the

drift, and in every case the door has closed just as expected.

The work through the rock is being pushed very rapidly, at some of the shafts between 800 and 1,000 pounds of dynamite have been used daily. Within the

form of shoveling machine built especially for this work so that it may be taken down the comparatively narrow shaft and be assembled to work within the small diameter of eleven feet, which is the size of the tunnel at the particular point where this machine is now being used. A photograph of this machine is shown herewith, and also a drawing illustrating the mechanism. The machine is controlled by a single operator and does the work of six laborers. It is provided with a double shovel, *A* and *B*. The section *A* digs up the rock and throws it upon the scoop *B*, which in turn empties its load upon a traveling chain conveyor *C*, the latter delivers the load into muck cars at the back of the shoveling machine. The letters *B*, *B'*, *B''*, and *B'''* show the successive positions of the scoop. The forward section *A* is carried upon a crank shaft *D*, which is revolved through the arc indicated by the arrow. Another arrow line shows the course of the front edge of the section *A*. The forward end of the scoop *B* rests upon the level of the section *A*, while its rear end is mounted upon a shaft *F*, which travels in a guide-way *G*. The forward section *A* is connected to the shaft *E* by means of side plates, indicated by dotted lines, so that as the crank shaft *D* revolves, the side shaft *E* is obliged to run up the ways *G*, as indicated by the letters *B'*, *B''*, and *B'''*. The section *B* is equipped with a small arm *H*, which carries a roller that is adapted to engage the cam groove *I*, causing the scoop *B* to turn over as indicated in the dotted view *B'* and empty its load upon the traveling conveyor. The machine is mounted on a turntable, so that it may be turned about in any direction.

Sum of the work on the city pressure tunnel has been hurried so far that certain sections are now being lined with concrete. The firms used for this purpose are very interesting. Our front page illustration shows their construction. They cover 120 feet altogether and are arranged in two sections, sixty feet of the tunnel being covered in an advance of sixty feet of the upper part. The first step is to lay the "invert," that is, a narrow segment of the lining running along the bottom of the tunnel. This,

Looking down the 441-foot shaft at 149th Street. Reinforcement for the caisson at Flatbush and Third avenues.

Shoveling machine for removing the broken rock and loading it into cars.

last year millions of pounds of dynamite have been exploded under the city, while most of New York was totally oblivious to the fact. Already a number of the tunnel sections have been "holed" through. To expedite the work, one contractor is using an interesting

lower half of the tunnel being covered in an advance of sixty feet of the upper part. The first step is to lay the "invert," that is, a narrow segment of the lining running along the bottom of the tunnel. This,

# The Heavens in March

## Eclipse of a Star by One of Jupiter's Moons

By Henry Norris Russell, Ph D

A VERY unusual piece of astronomical work, from a part of the world in which little has previously been done, deserves description this month. Though published in the German *Astronomische Nachrichten*, it originates in Chile where Dr. Hietenpatt, a German astronomer of distinction, is in charge of the observatory at Santiago.

On the night of August 10th, 1911, the third satellite of Jupiter, Ganymede, passed directly in front of a star of the seventh magnitude. In the constellation Virgo, and for observers in the southern part of the Earth, actually hid the star for more than four minutes.

The circumstances of this remarkable occultation were carefully calculated in advance by Stanislawski,

and it appeared that the best observing stations would be in South America. Dr. Hietenpatt, with great energy, set about the organization of observers throughout Chile, and it is undoubtedly due to his zeal and foresight that the important results which we are to describe were obtained.

Why it was important to have observations made at so many places as possible appears from the fact that since Ganymede is much smaller than the Earth, its shadow, if we may so describe the region from which at any moment it conceals the star, is only a little more than 4,000 miles in diameter.

As Jupiter and its satellite moved, this "shadow" crossed the Earth its center passing over the southern extremity of South America a little north of the Straits of Magellan while its northern limit reached barely to the boundary between Chile and Peru. Observers at southern stations would therefore see the satellite pass almost centrally over the star while for those in northern Chile, the latter would be concealed for a much shorter time behind the northern edge of Ganymede.

By comparison of the duration of the occultation as seen from different out places, it should therefore be possible to obtain very accurate information regarding the size and shape of the occulting body. In spite of unfavorable weather and other difficulties, the various observers—mostly school teachers or amateur astronomers—were able to obtain reliable observations at five stations, extending almost along the same meridian for 1,000 miles. Except at Santiago, the observers had only small telescopes of about four inch aperture, with which the satellite could not be distinguished, as regards its appearance, from the star, except that it was a little brighter. The two came closer together until they could no longer be distinguished, but formed one mass of light. Then, suddenly, the light diminished to about one half, this being, of course, the real instant when the star vanished behind the satellite. After a time the light increased again as the star came out, and then the mass of light gradually separated into two points.

In addition to these visual observations, a number of photographs were obtained by Dr. Zerkow, which defined very accurately the relative positions of the star and satellite before and after their conjunction, and made it possible to calculate just how far apart they would have appeared at any time.

In working along these lines, Dr. Hietenpatt found that it was not possible to get a satisfactory agreement between theory

and observation. It is necessary to assume that the satellite, like Jupiter itself, is flattened at the poles, for otherwise the calculated length of the occultation at the northernmost station, where the star appeared to pass just inside the satellite's disk, would be much longer than the observed time. As the rate of motion of the satellite is accurately known the maximum length of the occultation affords a very precise measure of its diameter. Dr. Hietenpatt finally concludes that the equatorial diameter of the satellite is 4,740 miles, and the polar diameter 4,300, so that it is a little more flattened in proportion to its size than Jupiter himself. The diameter of the satellite was previously supposed, from micrometer measures, to be about 5,000 miles, and the difference between this and the new

THE HEAVENS IN THE REGION OF LEO AND VIRGO

value is surprisingly large, but owing to the method of observation Dr. Hietenpatt's results seem to be entitled to very serious consideration. The mass of the satellite is known, from its attraction on the other satellites to be about 1/12,000 that of Jupiter or a little more than 1/4 that of Mars. But, according to the results just given, it is a little larger than Mars. This would make its density less than 1/4 that of Mars, and actually less than that of water—intermediate between the densities of Jupiter and Saturn. Even with this low density, it must be in rapid rotation with a period not more than ten or twelve hours, to account for the polar flattening.

It is perhaps most interesting of all to note that, according to the most definite of the observations, the disappearance of the star behind the satellite was almost instantaneous, the loss of light lasting only a second or so. This means that the apparent diameter of the star was not more than 1/800 that of the satellite, in other words, less than 1/2000 of a second of arc. This is quite what is to be expected for a star of the seventh magnitude, but it is interesting to have the extreme smallness of the apparent diameter of a star confirmed by direct observation.

### The Heavens.

We give again this month a detail map showing a portion of the sky which is now favorably placed for evening observation. Any one familiar with the constellations can easily pick out upon it the Sickle of Leo toward the west—that is, on the right, for an observer of the sky toward which we look upward the position of east and west if the north is at the top is never early different from what this would be on maps of the Earth's surface at which we always look down ward.

Among objects of telescopic interest here are Gamma Leonis, in the Sickle, a very well known binary pair, now separated in 15 seconds, and in very slow motion so that a complete revolution can hardly take less than

1,000 years. The bright star Regulus, at the end of the handle of the Sickle, has a companion of the eighth magnitude a little less than 3 minutes away, which in spite of its great distance from its primary shows the proper motion of the latter and is doubtless really as near it as it appears to be. Fifty-four Leonis in the northern part of the constellation, is a binary pair with components of the fourth and sixth magnitudes 6 minutes apart.

South and east, in Virgo, the star  $\gamma$  is a famous binary which has been followed for the greater part of its period of one hundred and thirty years. At present the two stars are at their widest separation about 6 seconds apart and can be separated with a very small telescope as can the pair previously mentioned. In 1848, however, they were less than one tenth as far apart as now, and could only be detected by the most powerful instruments of that day.

Two major stars which may be found near the northern edge of the map just north of  $\delta$  Leonis, is another very fine binary pair with a period of six years. The components are now at their greatest separation—nearly 3 seconds and can be resolved by instruments of very moderate power.

### The Planets.

Mercury is evening star until the 27th when he passes through inferior conjunction and becomes a morning star. He will not be seen until the 30th, when he sets about 7:30 P. M. Though only 15 degrees from the Sun he is north of him, and very bright (exceeding Vega or Arcturus) and being 13 miles, in a vision very poor in light stars, can easily be identified.

Venus is evening star too, at her greatest brilliancy appearing about twelve times as bright as Sirius and more than 100 times as bright as Alderamin. She casts a conspicuous shadow. If her light is allowed to shine through a window into a darkened room and on a wall, it will be seen in the distance if one knows just where to look. Shortly before sunset any one can pick her up, high in the western sky while the Sun is still shining.

At the beginning of March she sets about 9:30 P. M. and remains in sight until nearly 9 o'clock at the end of the month.

Mars is a morning star in Capricornus, rising about 5 A. M. Jupiter is likewise a morning star but is farther east, in Sagittarius, and rises about 2:15 A. M. in the middle of the month. Saturn is evening star in

## Queer Automobile Bodies

Some Interesting French Designs

THE development of automobilizing has been attended by a corresponding development in the construction of automobile bodies, even by an overdevelopment, which has produced queer forms that depart widely from the conventional types, although they are not always impractical or destitute of merit.

Most of these queer looking automobiles are of French make. A well known example is the Grégoire submarine, which conceals all but the head of the driver. The same firm makes a still more realistic submarine, which is provided with a conning tower and completely encloses the driver. Then there are cars shaped like artillery shells, with rounded tail pieces in which extra wheels or tires are neatly stowed and other shell types with glass skylights.

Three novel and bizarre automobile bodies of French make are described and illustrated in the present article, taken from the *Illustration Automobile* of Paris. The first is a Turcat-Méris body, which is called "The Shark" because it strikingly resembles that fish especially when seen from in front owing to the peculiar combination of the lanterns with the mud guards. This constructive device was first suggested in a Napier car, which was shown at the last Olympia exhibition in London and in which the front lanterns were mounted on the ends of the guards. The next development was the mounting of the top lantern on one of the rear mud guards. Finally an ingenious constructor conceived the idea of incorporating the lanterns with instead of mounting them on the guards. This construction is certainly queer, but it is eminently practical if it is solidly and substantially executed because the lanterns sharply mark the two extreme front points of the car.

The other two cars herewith illustrated represent two solutions of the problem which many constructors have attacked with more or less success, of producing an open car which can be converted into a closed one without showing at all times the mechanism and the additional parts by which the transformation is effected.

One of these vehicles, the "torpedo" made by Turcat-Méris, is provided with a canvas cover, which can be entirely concealed in the body of the open car so that the graceful lines of the torpedo are not marred. This cover affords complete protection and is provided with glass windows.

Still more ingenious is the Phenix officially designated *Torpedo convertible*. Inside it a *disappearing* complete car is controlled from the inside of a hood which can be made to disappear completely. Two-seated closed cars controlled from the inside are now very popular and in many styles, some of which are very luxurious and costly. The new Phenix car appears to furnish every possible grade, from the completely closed and the entirely open vehicle. It also pre-

New Phenix car, entirely open.

Hood of new Phenix car, closed.

Hood of new Phenix car, half closed.

Front view of "The Shark."

After part of "The Shark."

"The Shark," so named because the peculiar combination of the lanterns with the mud-guards suggests a monster of the deep.

sents a very graceful appearance, and lines show originality. The hood is composed of two quarter cylinders, which turn in pivots and can be raised and lowered separately.

The sides of the hood are glassed, and there is a blinged glass window in its convex front. Behind the hood is a disappearing seat for a servant. The front part alone gives sufficient protection against an unpleasant head wind in other wise agreeable weather. When the front part is dropped a small portion of it remains to form a wind shield of the usual type.

### Treating Table Refuse for Animal Food

A SOMEWHAT original method of securing food for animals from other waste substances is now being applied in Germany, and it appears to be worthy of note on account of the economy which could thus be secured. At Charlottenburg the city regulations require that all remains of food be placed apart from other household waste, such remains being collected separately each day and taken to a special plant, where they are treated so as to obtain a food product. They are first freed from all non nutritive matter which is always present, then the material is ground, pressed and dried and finally transformed into a kind of meal which is sold under the name of "bread meal." This is used in the original state or mixed with molasses. It is fairly nutritive but has a large percent of ash, this being due to the large quantity of bones contained in the waste material. M. Hansen made experiments with the meal in feeding milk cows, and the tests here upon 70 head divided into three lots, lasting for over three months. The results were encouraging and he considers that the meal should be used alone without mixing with other substances. He brings out the advantages which would be obtained in the way of economy and figures that should such a method be applied in German cities of over 200,000 inhabitants each, totaling 9,000,000 population, the yearly product would be valued at \$2,500,000 for stock raising purposes.

### Sharpening a Pencil

AN expert manual training man talked with the writer about so simple a thing as sharpening a lead pencil. In the first place, he says, the knife should not be over sharp, but should be a little dull, as if too sharp it will cut quickly through the wood and cut away the lead. If you remember, that is just the way a keen blade will use up a pencil. Then again, he says, it is best to hold the pencil in the left hand with the end to be sharpened pointing away from you and to cut away with a pushing cut, rather than toward you with a drawing cut, so when the point of the pencil is rotated against the side of the thumb and is sharpened by a draw cut stroke of the knife blade.

### Floating Civic Arts Building

**A**N interesting and thoroughly modern suggestion is given by a "sketch model of a proposed Civic Arts Building" at the exhibition of the Architectural League, 215 West Fifty-seventh Street. Made to scale it would be a circular building about 480 feet in diameter, with a well proportioned colonnade of early Doric type encircling it, and with a portico at the principal entrance.

This structure, rising abruptly from the water, suggests that the building occupies an island site, but it is in reality upon a buoyant concrete foundation. The foundation has the form of a great double walled bowl with ledges built in amphitheater form on the inner wall on which would be placed regular theater seats. The inner shell of the bowl is a segment of a sphere of smaller radius than the outer one and contacts with it at the lowest point. From this point a down or more vertical wall, connecting the two, radiates to the circumference, dividing the intervening space into as many water tight compartments.

This building is proposed as a desirable city enterprise for the maintenance of a civic theater, concert hall, arts and crafts schools, exhibitions and competitions, the discussion of civic public art and other matters—in a word the art and civic center of the people, to be moored at some such accessible point on the water front as Battery Park, where mooring privileges are controlled by the municipality.

The plan (written at no cost) is also more desirable than \$5,000,000 could secure.

It is the conception of Robert Palco, a sculptor of decided character and originality with a natural affinity for engineering activities, who has several other practical achievements to his credit among which is the sculptor's painting or enlarging machine.

### Friction of Gas Flow in Pipes

**I**T is not the intention of this article to impugn the accuracy of the formulae of Wislizenus, Hanks and others with regard to the friction of steam flow in pipes, but whether through neglect of the principles laid down by these authorities or through improper and unintelligent application of them certain it is that there are to-day in what is called successful operation many power plants which show on careful analysis of steam meter and other records a loss of power in the piping system which is truly appalling.

A striking illustration of the effects of pipe friction came recently to the writer's attention in the course of some experiments on a medium sized vacuum cleaner such as would be installed in the basement of a four room dormitory building. Several cleaners of rival makes were being considered, and as all operated on sweeping tests about equally well, it was determined to conduct accurate and thorough tests on each.

With this end in view, a test of galvanized iron, No. 30 gauge, ten feet long and of six inch internal diameter, was fitted at either end with a cone of the same metal, terminating in an opening of  $\frac{1}{4}$  inch internal diameter. Measuring device being fitted to the cylinder for determining the volume of air delivered to the machine, one of the cone ends was attached directly to the machine, and to the other was coupled ten feet of reinforced rubber suction hose of  $\frac{1}{4}$  inch internal diameter. The end of this latter hose was open and fitted with a coupling to take the various sweeping tools.

The pump being started, the first run was made by detecting this suction hose from the cylinder, in order to get the free delivery volume, velocity, etc. The hose was then attached, with the intention of attaching the various tools to determine their resistance to the admission of air. The pump being again started, with the hose end open, the gauge showed about five inches of vacuum when the tube suddenly and completely collapsed, as is shown in the photograph. The iron pipe was later subjected to the following tests:

Proposed Floating Civic Arts Building to be moored on the water front.

Rear of the building showing the bowl-shaped buoyant foundation.

The pipe collapsed by vacuum produced by friction of air

Tractor leaving its trailer to be unloaded while it returns to the coal yard with an "empty"

A two-wheeled automobile.

tuted for the latter, and the several arrangements are clearly shown in the cut.

The cause for the collapse of the tin tube could be nothing else than the creation of a vacuum within the cylinder because of the resistance of the ten feet of open hose as the cylinder without the hose withstood the pressure without difficulty. Had the end of the hose been closed in part by the attachment of a sweeping tool, the result might have been expected. Further, this collapse was occasioned by the friction of air at comparatively low velocity. To how much greater or deeper, then, must friction be present in pipes through which steam is radiating at high velocity and how especially pronounced must be this effect when it encounters a right angle elbow?

### The Three-wheeled Tractor

**T**HE vital problem of satisfying the ever increasing demand for trucks of larger capacity has led to the advent of the three-axle tractor-trailer method of transportation in which all the propelling mechanism is carried entirely separate from the load-carrying vehicle. One of the important advantages of this method is the economy in tires and wear and tear of the mechanism. The major portion of the load is not carried on rubber tires, but on the steel wheels of the tractor which saving alone would pay half the total expense of the largest truck.

A rear wheel drive machine has a tendency to push the front wheels down into the road surface, a front wheel drive pulls the rear wheels up and over. This difference in tendency is so marked that the same power plant, gear ratio and propelling mechanism will give far greater results in speed and pulling ability in a tractor than in a truck.

With a single tractor several trailers may be used one being delivered while another is being loaded and a third being unloaded thereby keeping the motor part active all the time or special unloading trailers may be used in some such lines as coal, ash, garbage, etc. one trailer having delivered with a chute load ten loads of lime, taking time to a distance of three miles, making the enormous total of 270 ton miles for one day. A certain development company uses a twenty and thirty foot, 17 or 20-ton load from a chute and unloading by dumping, each operation taking less than a minute. Such large units are easily handled by using a single steering wheel. The wheel may be turned to at least 90 degrees pivoting the unit at or near the fifth wheel the entire vehicle being capable of turning around in a twenty two foot street.

### A Bicycle Automobile

**A** TWO-WHEELED automobile of unique design has recently been perfected by a western man which differs greatly in its construction from a motorcycle. In fact, the two have little in common. It is like an ordinary automobile, with the exception of the number of wheels.

There are two runners under the foot board and when the operator releases his hold on the steering wheel these runners automatically lie down on the ground and level the machine in an upright position. The wind shield is a small oval-shaped glass with a convex surface to the wind large enough to protect the driver's face.

The radial frame, rear wheel suspension adds to the comfort of the passenger while an entirely different system of springs is used on the front wheel. The steering knuckles not only turn the wheel, but shift the center of gravity making easy steering.

The engine is three by three cylinder under two cycle valveless type of light horsepower and an excellent muffler makes silent running.

Although the photograph shows only a one-passenger car, it can be used for two persons by adding a seat over the rear wheel. This is a regular cushioned seat like the front one. One can also adjust a deck over the rear wheel and use the automobile for delivery purposes.

## Could take the roof off factory

and let the sun shine into every corner, how much would the extra light be worth to you? It would reduce your lighting bills, increase the efficiency of your employees, enable you to utilize floor space now useless for fine work.

*You can get a lot of extra daylight without taking off your roof. You can get an increase of 19 to 36 per cent. These figures are from the New York Electrical Testing Laboratories. They are the result of scientific tests of an interior paint which will not absorb and waste the light from your windows, which will reflect every ray down on your machinery and into the dark corners of your plant.*

Rice's Mill White is the paint. It has increased the daylight in many plants. One prominent manufacturer writes that he estimates he is getting 50% more light than he had before he used it. The R. J. Reynolds Tobacco Company says.

*"We have been too busy to make tests or determine with scientific accuracy the percentage of light increase in our plant afforded by the peculiar qualities of Rice's Mill White, but we imagine that such tests will show an increase of between 20% and 25%."*

*"As you claimed, it picks up and carries along the light to those points at greatest distance from the windows and artificial lights. It has given us a smooth, tile-like surface of white, without a tinge of yellow, and it has remained firm and unbroken, despite the jar of heavy machinery."*

### A Sanitary Paint

Rice's Mill White gives a smooth, glossy, tile-like surface. It offers no lodgment for germs and odors, can easily be kept clean, and will not flake and scale like a cold water paint.

### Rice's Mill White is economical to apply

A 4-inch brush spreads it without dragging and leaves no brush marks. Two coats equal three of lead and oil. Recoating is seldom needed, for it stays white longer than any other glass paint.

We were the originators of "Mill White" paint. Rice's paint is made by a special process, which no other manufacturer can use.

*For the greatest amount of light, the highest sanitary walls and the lowest final cost, paint your ceilings and walls with Rice's Mill White Paint.*

Rice's Mill White Paint is sold direct from our factory in barrels containing sufficient paint to cover 20,000 square feet one coat. If you have that area or more of ceiling and wall space to cover,

*Write for Booklet and Sample Board.*

Ask for a copy of our booklet, "More Light." Write today.

U. S. Gutta Purcha Paint Co.  
No. 23 Dudley St., Providence, R. I.

### RICE'S Granolith

A tough and elastic permanent finish for concrete walls. Becomes a part of the cement to which it is applied. One coat sufficient, unless a gloss is desired. Makes the best possible primer on inside concrete and brick for a second coat of Rice's Mill White Paint, giving a tile like, enamel finish at no more expense than lead and oil paint.

**For Concrete Surfaces**

The money you stand for all you can get in a motor car

## Which Car?—It Is Hard to Decide, Isn't It?

**T**o you who are trying to decide which car to buy—we want to offer a few suggestions.

You have looked at many different makes of cars. You have found that in most respects they are very much alike. They have nearly the same specifications, the same equipment, the same general appearance—at least, while new.

You hear, in most salesrooms, the same talk about service, guarantee, taking care of owners.

And when it's all finished how are you to decide? Of all these apparently equal cars, sold by these apparently equal dealers, which one are you to select?

**T**o choose wisely you must remember that behind those apparently equal cars are unequal values. Behind these apparently equal dealers are unequal companies, unequal organizations, unequal factories. In these unseen things lies the difference between cars.

So you should look to these unseen factors. Study the cars of course. Insist that your car have all the modern features. But before you invest your money—whether you buy a Chalmers or not—be sure to get satisfactory answers to the following questions.

### 1. How long has the company been in business?

Is it a sound, well-managed institution? Has it demonstrated its ability to manufacture successfully? Is it progressive? Is it likely to be in business permanently? Is it big enough and strong enough to attract the best class of dealers?

The kind of car you get depends absolutely upon the kind of a company that is behind it. A strong, successful, well-managed company will not shirk in manufacturing. It will be able to afford experimental work, and thus keep always in the lead. It will be in no position to back up its guarantees.

No company is more firmly established or better managed than the Chalmers. It has long been "there" in its class.

### 2. Does the company manufacture its own parts or merely assemble?

This is a vital question. The company that manufactures its own parts is able to put into the car better value for your money, because it eliminates the parts maker's profit. It is able to manufacture more accurately, because it concentrates all its efforts on making parts for one kind of car—its own. Also the company that makes its own parts will be able to give you service and supply your needs for years to come.

No automobile company manufactures a greater proportion of the parts of its car than the Chalmers Company.

### 3. What do owners say about the car? Are they satisfied?

Owners of a car are the people who know. They are the ones whose opinion is the result of experience—satisfactory or otherwise. Of course there is no car in the world—or any other manufactured product—that will earn the approval and endorsement of every single individual who uses it. But take the general opinion of the owners and you will make no mistake. Be guided by their opinion of car company and dealer.

Chalmers owners are satisfied. We are glad to have you ask their opinion of Chalmers cars.

### 4. Has the car itself quality—or is it merely a collection of "features"?

Accessories and equipment that make for comfort and convenience enhance the value of a real car, but they cannot make up for any lack of actual quality in the car itself. Be sure that the car you buy has the real "class" and in built quality that come only from painstaking workmanship all the way from designer's drawing board to the final inspection department.

Chalmers cars have all the "features," all the conveniences that any cars have. In addition they have Chalmers "quality" in every line, in every part.

### 5. Will the car command a good price in case you care to sell it two or three seasons hence?

Of course you are not buying your car with the idea of selling it. But it is well to know you can sell it at a good price—if later you want to do so.

Furthermore, the cars that bring good prices at second hand are the cars that are standard, the cars that are built to last, the cars that the public knows are good cars.

Chalmers cars have for years brought the highest second-hand prices of any cars in their price class.

**"Thirty-Six"** (4 cyl. 36 h. p.) - \$1950  
**"Six"** (6 cyl. 54 h. p.) - \$2400  
**"30"** (4 cyl. 30 h. p.) - \$1600

(Prices include full equipment and are f. o. b. Detroit.)

**Y**OU will find that among four cylinder cars the Chalmers "Thirty-six" at \$1950 cannot be surpassed. Among six cylinder cars the Chalmers "Six" gives you absolutely all you can ask in motor car value. For those who wish a smaller car, the Chalmers "30" is still the leader in the \$1500-\$1600 class.

These cars have all the modern features of convenience and comfort. In these tangible, physical things they are not surpassed by any other car, even at twice the price. In power and speed, in comfort and convenience, in beauty, style and luxury the Chalmers offers you the utmost value.

But greater than these tangible things, more valuable to you, more worth the money you invest are the intangible things behind the car—the Chalmers factory and the Chalmers organization. Other cars may give you approximately the same "features" as a Chalmers, none can give you these added values that make the Chalmers the choice of the wisest motorists.

If you make careful comparisons, we believe you will decide on the Chalmers. And when you do we urge you to place your order at once. It's not long till spring now and the only way to insure early delivery is by an early order. Catalog on request.

## Chalmers Motor Company, Detroit

only as a last resort in severe tuberculous cases. He warns against the general use of the remedy until Friedmann has clearly stated of what his material consists. He refers to the relatively unfavorable animal experiments, which he calls fallacies.

Prof Orth reports that the animal experiments did not yield absolutely good results. The immunized animals did not live much longer than the control animals. They all acquired tuberculosis.

Felix Klemperer's discussion which was largely historical and along general lines, is immensely interesting but it would lead too far to repeat it, even in abstract. He does not believe that the curative remedy against tuberculosis has been found, that tuberculosis has been practically eradicated, as was announced by one of the gentlemen in the discussion, but he insists that essential progress has been made. He shows the importance of the suppressive action of tuberculin even of Friedmann's turtle tuberculin bacilli, which had rendered earlier experiments at immunization futile. He asks how Friedmann's remedy has been deprived of this action of producing pus. Klemperer agrees with Ullrich that prophylactically, i. e. for the vaccination of children, the use of Friedmann's remedy is rather premature.

Goldschneider speaks from the point of view of the practitioner. He asserts that the purely clinical improvement which has been described in the cases treated is not sufficient and demands documents and for better proof than has yet been afforded of the actual benefit derived from the remedy.

In the further discussion in which such men as Wolff-Plesner Rier and Gindler took part, similar reasons were advanced for exercising great care and for waiting. Gindler stated that a case of renal tuberculosis which Friedmann had declared to be cured had been improved, in fact he said that the disease was still progressive.

When we examine Friedmann's report in detail, we miss first of all the thoroughness and entering into essentials for which Koch's first account of the etiology of tuberculosis has given such guidance, the example, and which was followed by other investigators, for instance by Ehrlich in the announcement of his own view. Friedmann's account is not satisfactory and must be characterized as requiring far more than scientific. At the present day it no longer suffices to say that a remedy has cured or can cure tuberculosis. The cure must be established, first in a clinical improvement which may be temporary only and which as a matter of fact has been obtained by other remedies even better than could be done by Friedmann, and has been obtained in this country since 1877; then it must be shown that an actual immunity demonstrable by laboratory tests, by the demonstration of specific antibodies, has been produced, and that this immunity persists for weeks, months, years. It does not appear that Friedmann has made even the simplest serum tests, those for agglutination, all of which Koch had shown the way twelve years before and more, and although the behavior of the opsonic curve has been demonstrated conclusively to stand in positive relation to the clinical improvement and to the immunity acquired in the course of treatment.

Friedmann's experimental proof is still fully insufficient to establish his contention. The best he could show was that his experiment animals lived three or four times longer than the controls after virus infection, while it has been shown that with other remedies that experiment animals, notably guinea pigs, absolutely resist a virulent infection to which the controls succumbed in the course of a few months, and that the immunized animals were healthy and free from tuberculosis more than one year after infection.

Although, as pointed out by Clara and other men, the use of living tubercle bacilli is correct in the treatment of tuberculosis in principle, I maintain that the prophylactic use of such material in children and adults is little short of

criminal. Friedmann has advanced nothing but his own assertion that these living tubercle bacilli cannot change in their virulence and become harmful to the children. He can afford no guarantee that he has not infected these children and that eventually they may not acquire a fatal tuberculosis.

In spite of all the objections that may be raised against Friedmann's remedy or rather against his administration of it at present, and against his incomplete announcement, I am free to admit that there may be, and probably is, a great deal of good in it. It certainly has clinical improvement in a great many cases, which has been confirmed by children and by the physicians in charge. We have the disappearance of physical signs, the gain in weight, the restoration of the working ability, the loss of tubercle bacilli in the sputum, even the loss of a positive tuberculin reaction. The only question is whether equally good results cannot be obtained with a less questionable but less potentially dangerous remedy. This has been done.

Dr von Ruck in this country has shown that it is not necessary to inject living tubercle bacilli for the purpose of successful immunization, but that a proper combination of the various extractives will accomplish this purpose with equal efficiency and certainly with far greater safety. He has even succeeded in raising the suppressive action of the tubercle bacilli by a proper balancing of the constituent fats, or perhaps better by removing the excess of fats and waxes from the tubercle bacilli. He has had to be responsible for almost fatal outbreaks after hypodermic injection.

In children who are subjected to prophylactic inoculation with this remedy, which is ever chiefly an experiment, it does not contain living tubercle bacilli, the most surprising clinical improvement was shown especially a decided improvement in nutrition, a disappearance of all low rounded signs, as they had indicated of lung signs of enlarged lymph glands, of anemia, etc. and what is more significant, the seen of all these children showed a progress, increase in tuberculosis antibodies, tuberculin and complement opsonia. Further this showed, and can thus be shown, that the power to dissolve tubercle bacilli *in vitro*.

### The New York Motor Boat Show

THE Motor Boat Show in Madison Square Garden this year was perhaps the most successful exhibition of marine equipment. There was also a splendid display of boats of various types, though the boats were not as numerous as heretofore. The cruisers were represented by two large 46-foot boats, the expensive pleasure craft in a 54-foot "Speedway de Vitesse," having a glass-enclosed cabin in the front and a commodious open cockpit in the rear and the speeds runabouts and hydroplanes in a dozen or more boats ranging from 16 to 25 feet in length.

As heretofore, the cruisers are fitted with every convenience. On account of the high price of gasoline engines are being made to reduce the fuel consumption to a minimum by means of economical carburetors but there did not seem to be any tendency to use kerosene or crude oil. The hydroplanes, of course, attracted the most attention, especially since they have almost completely taken the place of the displacement type of boat. Even that well known builder of steel boats, W. H. Mullins, has brought a 16-foot hydroplane hull which, equipped with a 3-cylinder, 2-cycle motor of but 18 to 25 horsepower, is designed to travel at the rate of 28 statute miles an hour, and this at a moderate price. An ordinary steel launch with inboard motor in the cockpit can be bought for \$300, it is claimed.

The hydroplanes were of all types—monoplanes, single-step, and multi-step. The chief representatives of the second class were the "Baby Belloz 11," winner of one of the three races for the Harmsworth Cup last September, and a new hull, intended to be fitted with two 400 horse-power, 6-cylinder vertical en-

## A Dustless Thoroughfare

"TARVIA B" is a tar product which is liquid at normal temperatures and can be spread on the surface of a macadam road by a modified spreading cart, no other apparatus being necessary.

The usual procedure is to sweep the road of surface dust and dirt, apply the Tarvia B and keep the traffic away for a few hours until the Tarvia has penetrated into the road surface. The grade of Tarvia is used only on roads where the rolling action of traffic has made the surface between the wheels very small. As this accounts a danger grade of between would not do, because it could not penetrate into a closely bonded surface. Tarvia B, however, finds its way into such surfaces and forms a matrix, holding the fine screenings in position, preventing raveling and thus preventing the formation of dust by automobile traffic and greatly prolonging the life of the roadway.

BARRETT MANUFACTURING COMPANY

New York, L. I., Buffalo, Philadelphia, Boston, St. Louis, Kansas City, Portland, Chicago, Baltimore, Pittsburgh, Seattle, Los Angeles, THE PATERNITY MFG. CO. Ltd. Montreal, Toronto, Winnipeg, Vancouver, St. John, B. C., Halifax, N. S.

A typical instance of the use of Tarvia B in Norway. Comm. Mr. E. C. Lilland, the Street Commissioner there, wrote as follows:

November 15, 1912  
"You ask for opinion concerning Tarvia B to which I will say it does not have it any equal. We have used this material for three years and the more it is used, the better satisfaction it gives, as to preserving the road and lasting longer. We have the last year used this material on two miles of streets and on day those streets are in excellent condition after the traffic of heavy teams and autos."

In addition to Tarvia B there is Tarvia A for hot surface application and Tarvia X for road construction.

# Knock Down Frame With Full Size Patterns To Finish By — Only \$28

## Easy to Build You'll Enjoy It

This Brooks 23 foot Raking Transom Stern Motor Boat has a speed of 9 to 14 miles per hour—exceeding capacity 12 persons. We furnish knock down frames with patterns or complete knock down boat, including male covers, hulls and fittings for finishing. Inexpensive, every step of work, plan and clear. You'll find a boat easy to build if you can handle a hammer, saw and screw driver. Plans carefully fitted have in factory ready to put together. If you prefer you may build from patterns and come from 1 to 12, according to size boat. Transoms have made Brooks boats are enthusiastic.

No means you who should have this handsome boat. *Steadily—speedy—comfortable.* A better looking, sturdier, faster craft than the best boat could make for three times the price.

### Write for Brooks Book of Power Boats—Sail Boats—Row Boats—Canoes

"Send a post card today for the Brooks 72 page book of boats and rowers—complete table illustrated. Diagrams of motor and sail boats, of all sizes, boats, transoms, hulls, and fittings for finishing. Send for it. It is yours. Lots of satisfaction in knowing your boat is sound and stands in every part from stem to stern."

Send the book with our offer. Write—*Wm. A. Brooks*

step driving twin screws. The multiple-step hydrazine advocated by William H. Fauser, was illustrated by 25-hp "Eco-Boat" which was built by the author. It has 60-horse-power 5-cylinder and 4-cylinder vertical engines, respectively. These engines have made 46.8 miles per hour and 35.5 miles per hour in 1000 ft. races. Their bottoms are covered with sheet metal having small V-shaped corrugations running lengthwise of the hull, the V's being 1/8 in. deep and 1/4 in. wide. The corrugated metal covering is arranged in 4 and 5 low steps (about an inch) on the low powered and high powered boats, respectively. The hulls are covered with a wide open V throughout its entire length. Longitudinal slots are cut in the vertical sides between the bottom plank and the hull plating to allow air to flow in and thus keep a vacuum, with the consequent drag, from being produced. The "Eco-Boat" was built by the author at the International races previously mentioned, was a 5-step Fauser hydrazine. Propelled by two 350-horse-hydraulic engines, it won the 1000 ft. race in 10.5 hour in the race as against 22.75 miles per hour scored by the "Baby Reliance" 11 fitted with a 150 to 180-horse-power engine. The "Eco-Boat" is a motor boat in the race which this boat won.

[illegible]

The placing of the motor in a separate compartment in the bow of the boat, which is almost universal this year, makes it difficult to adjust and to start. Consequently either a starting crank is provided in the cockpit or an electric self starting outfit is arranged alongside the motor. This latter is a decided improvement, especially where the boat is to be used by ladies, as in addition to the self starting motor, electric lights are provided at night.

### Achievements and Lessons of the Scott Expedition

**I**T is, of course, too soon to tell the whole story of what the world has gained through Capt. Robert Scott's second antarctic expedition, in which the heroic leader and four of his companions so cheerfully laid down their lives. The scientific results of his previous expedition (1901 to 1904) filled twelve substantial volumes. It may be years before three of the second expedition are ready.

about the modern remains of this land mass could be explained as well on the assumption of an archipelago masked under a load of ice as upon that of a continent in fact up to a year ago there appeared to be strong reasons for believing that the so-called continent was cleft in twain by a broad channel connecting Ross and Weddell seas and this belief was only conclusively disproved by the combined discoveries of Scott Shackleton and Amundsen.

[illegible]

The second expedition which sailed in the autumn of 1910 was with the possibility except in a few instances the strongest of the expedition. The expedition was led by the polar explorer Shackleton a member of the first expedition had in the month of time returned to the Antarctic on his own made further explorations from the ship's old base and pushed over the Beardmore Glacier to a new and seasonal farthest south in the very heart of the continent. The expedition's original purpose was to make further explorations from the activities of the large and able staff of the four principal directions an expedition party was to explore King Edward Land from the west to the east. The expedition was led by McMurdo found a party was to remain at head quarters to carry out extensive scientific observations and a southern party led by Scott was to explore the order Sir Clements Smith would have to the only practical reason for continuing the expedition was to make magnetic observations. The expedition was to carry out a programme of scientific research as thorough as the most conservative of the expedition at home. The expedition was to make observations of the sun and the stars and the planets had to be made. The eastern party under Lieut Campbell was unable to land on King Edward Land, and proceeded in a sled to Cape Adair thus becoming the first to reach the Cape. The expedition's exploration in that region they were picked up by the expedition ship the Terra Nova and the expedition ship the Terra Nova and the expedition ship the Terra Nova. The ship was however unable to land on the shore on account of impassable ice and with very meagre stores and only a summer outfit they were obliged to turn back. The expedition was however ultimately making their way 200 miles overland to the expedition's base at Cape Evans.

A section of the Roof Garden where Love Brothers' "High Standard" paints and the other products are exposed along with all kinds of paint products to the sun, rain, snow, frost, dirt, mud and the fumes of the city smoke—does for five years. The paints are then preserved in their "Museum of Time," as a guide to estimating the highest possible efficiency in all Love Brothers' products.

### This Is The Way We Test Paints For You

Science with experience—not guess-work—is the guide in the making of High Standard products. The ingredients are selected with great care and are subjected to analytical tests to be certain that they come up to our ten definite high standards. They are then ground and blended together in the manner and in the exact proportions that years of exposure tests have proved to give best results.

This is why

**Love Brothers**  
High Standard  
**LIQUID PAINT**

goes farther, lasts longer and is more economical than ordinary paint. It will pay you to use High Standard paint over your own as it need of paint.

For the finest and most durable varnish, enamel, or interior gloss or rubbed finish it will pay you to use

**Love Brothers**  
Little Blue Flag  
**VARNISHES**

These Little Blue Flag varnishes for every purpose, considerably superior to its particular make. You will find it to your advantage to use our special varnishes. Write for particulars.

The proper finish for concrete work is

**Love Brothers**  
**CONCRETE AND CEMENT COATING**

This coating film and seals the pores, makes a moisture proof surface, resists the action of alkali and prevents discoloration and makes a hard, smooth, gleaming, durable finish. It comes in a liquid form ready for use—14 colors.

For concrete floors see Love Brothers' Elastic Cement Floor Finish. It makes a smooth, hard, glass surface, prevents wear and floor dust, and is easily cleaned. A very durable and satisfactory finish.

### Valuable Books—Free

Interesting and useful booklets prepared by experts on these and other "High Standard" products will be sent free of charge. There is a Love Brothers' Paint, Varnish, Enamel or Stain for every purpose. Send in most cases. One free one as a reminder, and write us today.

covered, among other things, a deposit of bituminous coal, evidence that a temperate climate must have once prevailed in this region. They also found thousands of singular insects of two species. The party at headquarters made very thorough meteorological and magnetic observations. A magnetic observatory was excavated in the side of a glacier to secure uniform temperature throughout the year. The physical work was carried out by Dr. George Simpson of the Indian Meteorological Department, who is a specialist in atmospheric electricity. Dr. Simpson returned to England last summer and at a meeting of the Royal Meteorological Society announced some very interesting discoveries in meteorological optics made during his southern sojourn. Upper air soundings were made with balloons to a height of 50 miles. A bold feat carried out in mid winter by Wilson Rowers and Garraud consisted of a five weeks' journey across the Barrier to study the incubation of the emperor penguins which breed in winter.

The suggestion made some months ago by Mr. F. H. Bish in the Bulletin of the American Geographical Society that Scott had chosen the meteorologically worst side of the Barrier for his inland route has been tragically confirmed. The weather conditions for which the whole periphery of the Antarctic continent is noted as a sometimes attaining a force of 70 or 80 miles an hour appear to be the result of air descending down the slopes of the vast ice-cap of the interior. In accordance with a well known law they are deflected to the left by the rotation of the earth. Thus the furthest hazards of the Barrier are mainly from the south east and a glance at the map shows that Scott must have experienced the full brunt of them. It was nothing of the fact that they delayed his departure from his base to a dangerously late period in the season. Amundsen's route, and especially the location of his base, was far more favorable with respect to these winds—and a comparison between his and Scott's experiences affords a striking lesson in arctic navigation. However, this comparison does not indicate better judgment on the part of the Norwegian explorer for his coastal route was chosen which it avoided in respect upon territory occupied by the other.

A comparison between Scott's and Amundsen's methods of travel lies beyond the scope of the present article but the writer may perhaps be pardoned for suggesting that Scott's preference for human power compared with other modes of traction seems the height of quixotism.

### The Heavens in March

(Continued from page 40)

Taurus setting after 11 P. M. (transit in A. M. in Capricornus rising about 4 A. M. Neptune in Leo transit and sets at about 4 P. M.)

The Moon is now at 7:11 A. M. on the 17th in her first quarter at 4 P. M. on the 15th full at 7:11 A. M. on the 22d and in her last quarter at 8 A. M. on the 29th. She is present on the 21st and farthest away on the 28th. As she completes her circuit of the heavens she passes 11 Jupiter on the 2d Mars and Uranus on the 4th Mercury on the 9th Venus on the 11th Saturn on the 13th Neptune on the 17th Jupiter again on the 20th and Uranus on the 11th.

At the time of full Moon on the 22d there is a total lunar eclipse. The earlier phases of this are visible in the eastern part of the United States and the whole eclipse on the Pacific Coast. The Moon goes almost centrally through the Earth's shadow and totality lasts more than an hour and a half. According to Eastern standard time the first contact of the Moon with the shadow comes at 5:19 A. M., totality lasts from 6:11 to 7:44, and the Moon leaves the shadow at 8:43. Only the beginning of the eclipse can be seen from Washington, but from points on the Pacific Coast by whose time all the phases occur three hours earlier, the whole eclipse can be observed.

## Notes and Queries

Kindly keep your queries on separate sheets of paper when corresponding about such matters as patents, subscriptions, books, etc. This will greatly facilitate answering your questions, as in many cases they have to be referred to experts. The full name and address should be given on every sheet. No attention will be paid to unsigned queries. Full hints to correspondents are printed from time to time and will be mailed on request.

(12715) C. W. R. writes. In reference to query 12741, please allow me to say that there are no halibutes in the clouds for breeding single worms, loads of frogs. Single worms breed and live in the ground and they are so secure there that no wind is sufficient to suck them out and up to the clouds. But as their enemies, the birds, prey on them during the daytime, they have become night workers, and parade mostly in the night, and especially during warm rains. The worms P. A. F. saw came out during the several hours of rain, but a sudden change to more mild weather kept them in and they had to wait until the accumulating earth had been blown to death where he found them. Of course, everybody knows that toads and frogs breed in water. As soon as they have developed their tadpoles, they generally change their dwelling places from water to land during a warm rain in spring and early summer. Their sudden appearance at such times has developed the popular fallacy that they have rained down. Now are not these common sense explanations more satisfactory than the scientific knowledge? A. There can be no doubt of the common sense explanation. It is a explanation of the phenomenon in question. Now is there any doubt that in certain storms there is an upward current sufficient to raise small animals and carry them long distances before they drop out of the whirl. Waldo's Elementary Meteorology page 163 states that "upward currents 0.1 inch diameter require an upward current of only 16.5 miles per hour to sustain them when the air pressure is 28 inches while steady rain will prevent air current of only 3 miles per hour to prevent their falling to the ground." It is true that in a descending current in a tornado had a velocity of 100 miles per hour when the pressure of the air is 15 inches, this would mean that small insects 1/2 inch in diameter from falling to the ground. These ascending currents exist in all violent storms and is sufficient to carry a human being. Any particular instance must be determined by the circumstances of that particular instance and cannot be determined by any general belief in the possibility or impossibility of the carrying up and dropping of small things from the clouds. We grant that this explanation should have been given in the former note so that the meaning might have been clear. Our meaning was this: Whether small worms were carried up in the particular instance must be determined by a knowledge of the force and character of the storm in question conditions which we did not know. The only condition we intended to state was the possibility of such an occurrence with a sufficient velocity motion of the storm.

(12714) J. C. D. asks. Please explain in non-technical language how the Chinese use the Chinese alacuse to point. And why other nations do not use it. A. The Chinese alacuse is simply a counting board on which the results of computations done in the head are tallied, as it were. It is a shallow box divided lengthwise by a bar and having several rows crossing the bar and passing through the bar. On one side of the bar are five balls and on the other side there are two balls. The five balls stand for units, and the two balls stand for five each or ten balls together. When the five balls on one side have been tallied one of the two balls is pushed up; the five balls are pushed back and the tally proceeds till another five has been tallied when one of the next wire is pushed up and this too (or two) is pushed down. As long as may be taken as units. Those to the left will be tens hundreds etc. Simple tallying of calculations is done on the alacuse with rapidity, but if a mistake is made it cannot be detected. The work must be done thoroughly. A similar instrument was employed in ancient times by the Romans, but modern nations discard paper and pencil a better way to perform their reckoning.

(12715) H. J. S. writes. Recognized as the only authority I seek information. Is it necessary for one to stand on all three rails of a third-rail system in order to get a shock? Am not the two running rails connected as one arm of a circuit, with the third rail as the other? Is it not possible to stand on the third rail and one of the running rails and receive a shock? Also in railroads a short circuit is caused as a receiver's shock standing on the third rail alone? A. A third-rail system the two rails which carry the current are connected to the earth, and cannot give any shock by themselves. The current comes by the third rail from the power house and the third rail is changed in its voltage all the time. Standing on the ground or on one of the rails of the track, you will certainly receive a severe shock by touching the third rail and one of the third rails, no shock would be felt, then there is no way for the electricity to escape from you to the earth. If you step off and will receive a shock when you get one foot upon the ground, the other being on the third rail.

## The Proposed New Patent Office Building

On February 10th, 1914, Mr. Burnett of the House Committee on Public Buildings and Grounds reported a bill on public buildings. Section 15 of this bill authorizes the creation of a commission composed of the Secretary of the Interior, the Commissioner of Patents, and the Supervising Architect of the Treasury to select plans and estimates to be made for a building, to accommodate the United States Patent Office.

The President's Commission on Economy and Efficiency, in its report of the investigation of the United States Patent Office pointed out the necessity of a new structure in no uncertain terms. In the case of the entire force of the office numbering 1200 people, says the report, it is quite evident that the best results cannot be obtained without better quarters.

The present building was completed in 1897 and the new wing is now forty-five years old. With the building was probably adapted to the use to which it was put at the time of construction. It is completely unsuited to present conditions. The report of the President's Commission points out that the amount of breathing space allowed to employees is most inadequate, under the present system of ventilation and that this system cannot be improved because of the large number of persons who are compelled to work in very confined quarters. The space consumed by the rooms of the examining divisions is from three to five or more times that found in most offices.

The basement floor of the Patent Office is occupied in part as a storeroom. The condition is a disgrace to the Government. Part removed from the streets is deposited on the floors—large stones between which are large cracks—and accumulations in thick layers on the publications. The condition is aggravated because the sale copies of patents, of which these publications are chiefly composed, are open both in front and rear so that the dirt and dust cannot be excluded. Much handling of the publications (they are frequently carried) sits up the dust, so that it seeps into the working rooms of the examiners adjoining the files. Apart from considerations of health and efficiency, there is the risk of fire. There have been two serious fires in the Patent Office. In one of which all the original records were destroyed. If burned or gutted the record of ownership of the patent property of the whole country would be lost, causing irreparable injury to many inventors, designers, and manufacturers. While the possibility of loss by fire applies to the Patent Office as a whole, it is particularly applicable to the basement records. The recorded transfers of inventions made by patentees in the United States Patent Office are probably the only recorded evidence of the titles to millions of dollars invested in patent rights.

The President's Commission as a result of its investigation recommends that an appropriation be provided for the construction of a new building to be used exclusively by the Patent Office and to be properly designed and equipped. The Commission estimates that a suitable building would cost between four and five million dollars, which does not include the cost of site, water, heating and lighting, and other necessary expenses.

The House Committee on Public Buildings and Grounds has had under consideration from last seven hundred bills. The total appropriations called for by these measures is more than three hundred million dollars, while the total authorization recommended by the

Committee is less than one twelfth of that amount. It is sincerely to be hoped that the Patent Office will not be ignored and that Mr. Burnett's proposals will be accepted by Congress.

## Modern Arguments of Science

A N array of scientific workers all over the world is faithfully laboring, and advancing with slow but sure progress the frontiers of our knowledge. Science has become a systematized, and a gradual widening of our horizon assured. But no systematic gain can secure for us the fruits which it is reserved for the great genius to gather. The resources of men like Sir J. J. Thomson, Sir William Bragg, and others, are not a few others stand on a wholly different plane, and must not be compared with the work, however expert, of the rank and file in science. Much none do not follow the beaten track, where some degree of success is assured to him who has reasonable skill and sufficient perseverance. They achieve that which to the average man would have appeared impossible—until it comes, an accomplished fact.

In the article just read by radium with a velocity of 120,000 miles per second, a Fleming recognizes an atom of hydrogen. A Rutherford achieves the incredible task of counting the number of molecules in a measured quantity of gas. A Perrin prepares an "artificial gas" made up of a vast number of particles of nearly equal size (thus mimicking the molecules, and furnishing a more accurate picture of the character of the properties of a typical gas). A J. J. Thomson constructs a miniature sun three inches long and having a bare one hundred and fifty of an inch, and with it shoots molecules at a muzzle velocity of some ten thousand miles per second. He does this to determine the weight, which they are made to register on a photographic plate. Is this a fairy story? No, it is far more wonderful than any fairy story, for it is the achievement of man in the twentieth century.

What reasons, for instance, are there? We dare not prophesy. There are rumors of the synthesis of matter, the building up of molecules from simpler bodies, or perhaps from something which is not matter. These rumors may prove unfounded. What then? They are rumors, and we must wait. And the future surely holds a richer harvest still in store.

The reader who seeks further information on these things will find it on another page of this issue and in several important articles in this week's *Scientific American Supplement*.

## Economy That May Be Disastrous

WE have before us a photographic reproduction of a target after it had been fired by a battleship which used a new system of fire control that enabled the ship to deliver the projectiles of a whole broadside at the enemy's mainmast. The target is in the position in which it was hit. Instead of the separate and single shot holes obtained under the present methods of firing this target has huge well-defined gaps ten to twenty feet in diameter, which seem to indicate that a whole salvo of fire or ten 12.5-inch shells passed through at those points. Under this system the whole battery is aimed and fired by one man, the errors of individual pointers being eliminated. The significance of the result will be the more appreciated when it is known that the firing was not directed in water level, but in a way which would send the firing ship to sail rather heavily.

It is a common saying among the officers of our navy that the first salvo which lands will settle the fight—so great will be its moral and material effect. That statement was, however, not to collect out. In the present practice in which such shots of the salvo as landed would be scattered on the ship, whereas the target above referred to proves that one foreign navy, at least has developed a system by which the whole battery of ten or twelve heavy guns can be enabled to land the projectiles within a limited area of the enemy's ship.

Now since it will be possible in this system to land at least one such salvo (provided of course that the range were not lost) at intervals of a minute or less it must be delivered in the very time that the naval battle of the future will be decided not by hours, but by minutes.

In the contest between gun and armor, the victory today is decidedly with the gun. Our own 14-inch guns can pierce armor after the present fighting ranges, and already 15- and 16-inch guns are under construction for some foreign navies. In spite of their exceedingly heavy armor, not even our own "Pennsylvania" and "Nevada" could withstand such an attack as this method delivered in the case of the target practice above referred to. One single concentrated broadside might easily disable her, and it would not take many such to send her to the bottom.

It is certain that among the leading powers there is an element of naval efficiency to which no match

thought, attention and practice is given as it has of good shooting. No one may will have any monopoly of this. It is reasonable to suppose that the ships of our battlefleets ever did themselves drawn up in line against those of an enemy, the shooting of the foe will be just as good as our own. If this system of one-man control of the fire becomes general, as it must do in the course of the war, it is evident that the element will belong to that fleet which is able to place the greatest number of heavy guns along the battle line. In the future battleship fleet Providence will certainly be on the side of the heaviest artillery, and a preponderance in ships and guns will probably spell an early victory for the fleet that has it.

The Scientific American is to-day, as it has always been, a most earnest advocate of peaceful methods—where they are possible. We are strongly in sympathy with the efforts which have been made to bring about universal arbitration. At the same time we believe that one of the strongest influences making for peace, particularly in the case of this country, is the possession of a navy sufficiently strong to cope with any international emergency which may arise. Do we possess such a fleet? We do not, and that our navy is far below the strength which it should have, and is in danger (if the present military policy is followed) of falling yet more below that standard, is evident from the following comparison of our strength with that of the fleet of Great Britain, the fleet of Japan, and, of course, that of Great Britain in the two oceans.

If Congress makes appropriation for one battleship only this year the vessel may possibly be in commission by the year 1916, and if so, a comparison of our battleship fleet with that of Great Britain, Japan, and Germany shows the following results:

Assuming that the battleships, as their name suggests, will be put into the battle line of a great engagement, we find that in the year 1916 Japan will be able to oppose our top dreadnought battleships six battleships and seven of the largest battle-cruisers, making thirteen vessels well armed and carrying the heaviest guns, and that Germany can oppose eight armored cruisers and seventeen battleships against our ten battleships of the latest type. We do not, however, say that Japan would be in a position to oppose a first fighting line of thirteen ships to our ten, with a reserve of twelve first-class ships to replace their first line, should it be badly pounded or, what is more probable, to engage our fleet simultaneously on the other broadside. In the presence of these facts we ask: On what one side theory of patriotic and far-etched statesmanship, is the House of Representatives proceeding in its present opposition to the demands of the country for an adequate navy?

## The Money Value of Street Lighting

THOUGH most prosperous, the most talked-of street in the western hemisphere is Broadway, New York. Electric lighting made it so. Its millions of electric bulbs stand for business enterprise, wealth, prosperity. That good street lighting means dollars and cents to a community, the city of Cleveland has demonstrated to the satisfaction of all. A department on the north side of Euclid Avenue, between East Fifty-fifth and East Sixty-sixth streets, installed a block of ornamental street fixtures. The result was magical. That side of the street was crowded, the other side, deserted. The estimated value increased on the crowded side and decreased on the dark side. Not only did the sidewalks were equally well lighted was a commercial equilibrium established on that particular section of Euclid Avenue. Similarly, in Westwood Street, between Fourth and Seventh streets, in Miami, Fla., was transformed from a gloomy, deserted, and unsafe street by the installation of structures, into a prosperous street in which new buildings took the place of the old—a result accomplished entirely by street lighting.

Three hundred cities in the United States and Canada have tried ornamental street lighting, and have found that it pays as a municipal investment, as well as in heightened civic pride, in greater prestige, and, therefore, in better citizenship. Cities, like human beings, are judged by impressions. The feeling of safety and security comes from the steady glow of a railway train that stops for a few minutes at a station leaves an indelible impression upon the traveler. If he sees nothing but forbidding gloom, punctuated by an occasional flickering gas lamp, he inevitably feels that the country is a place of lawlessness and uncertainty. If he catches a glimpse of a main street ablaze with light, he knows that here business thrives, gloom means dirt, decay, stagnation; light means activity, industry, life. From the lighting of a city the character can be learned as readily as from the

# Salt-rising Bread

## Raising Dough With Newly Discovered Bacteria

By H. A. Kohman, Senior Fellow of Bread Research, University of Pittsburgh

**[T]his author holds a fellowship granted by the National Association of Master Bakers for Research on the Chemistry of Bread, under the direction of Prof. Robert A. Howard, Director.**

The history of bread extends over incalculable time, and its origin is quite obscured in the mists of antiquity. The words "bread" and "leaven" receive mention in Genesis and Exodus and other books of the Old Testament, indicating that baking as an art was practiced in remote ages. The early discovery of the leaven process was without a doubt purely accidental and may be traced to the fact that in eastern countries a mixture of meal and water if forgotten for a day will ferment. This simple way of inducing fermentation is together with the advantages of light bread soon led to the adoption of the leaven process.

Although leaven was used even in ancient times, bread making methods remained crude and uncertain and the nature of fermentation was not understood until recent years. It was the classic work of Pasteur in 1857 that proved beyond any reasonable doubt, that alcoholic fermentation, such as occurs in ordinary bread, owes its origin to one-celled, microscopical plants (yeasts). As the result of this research and others, the manufacture of yeast has become a science and the old time leaven has been replaced by the almost perfect product now available. Naturally the progress in yeast making was followed by revolutions in baking. Yeast has proved to be literally the life of the baking business, and has made it one of the world's great industries.

While the method of preparing bread with yeast has been extensively investigated and the function of this microorganism in bread is thoroughly understood, salt rising bread has been peculiarly neglected. If we search the literature upon bread, we shall find volumes upon its preparation by means of yeast—and a mere smattering upon salt rising methods. Yeast bread is made upon scientific principles, but the methods for the salt rising type are as crude and uncertain as they were centuries ago. The housewife and the baker still rely upon the old fashioned empiricism and to them it is a matter of speculation why these so often fail to rise. Yet with many people salt rising bread is the favorite bread. Ex Governor Stubbs of Kansas is intensely fond of it and praises its strength giving powers. He is so fond of this bread that he induced his daughter to learn to make it by promising her a valuable prize should successful crown her efforts. At first she met with frequent failures, and at times was compelled to throw a batch out to the chickens.

There is no consensus of opinion in the literature upon salt rising bread. Most of the writers maintain that the gas for raising which serves this bread owes its origin to wild yeasts that accidentally get into the batch from the air or insects used. Accordingly then it is a matter of chance as to whether the bread rises or will not rise, and indeed failures are not uncommon. Some writers speak of a spontaneous fermentation and ferment, but do not specify what the germs are.

With the view of putting the preparation of salt rising bread upon a scientific basis, a thorough investigation was undertaken in the Department of Industrial Research in the University of Kansas, and completed in a similar department in the University of Pittsburgh. In this investigation surprisingly interesting results were obtained. A single study of the "empire" revealed the fact that it is not yeast at all, as has been maintained but certain bacteria that raise this bread. From the testing four of bacteria that occur in salt rising dough it was possible, with extreme difficulty and after many failures, to isolate a bacillus, which by itself can be used in making salt

rising bread. Not only was this bacillus tried in the laboratory, but in the home and bakery as well. A number of households used it with continued success, and in a modern, up-to-date bakery, where failures had been frequent, a month's trial gave perfect un-

derstanding of small, microscopical cells that must be magnified many times to be visible. Yeast cells are oval shaped bodies, while the salt rising bacillus is rod shaped. The cells of either are independent plants capable of life and reproduction. Yeast multiplies by a process of budding, while the bacilli reproduce by a division of cells known as fission. Hence the many fission fungi. Reproduction proceeds with surprising rapidity, a cell dividing about every eight or ten minutes. From this geometric ratio it has been carefully calculated that if there were sufficient culture media, and growth were not curtailed by prohibitive by products, the progeny of a single cell would, within a week, literally fill the oceans.

Chemically, this bacillus is easily distinguished from yeast. Yeast, as every one knows, decomposes sugar into carbon dioxide and alcohol, the former of which owing to its gaseous nature, aerates the bread. Unhappily enough, the same chemical changes that aerate bread take place in the production of all alcoholic liquors. The salt rising bacillus produces no alcohol, and the gas, instead of consisting totally of carbon dioxide, is two thirds hydrogen and one third carbon dioxide. Hydrogen is a very light, combustible gas, and in equal quantities will aerate twenty-two times as much bread as carbon dioxide. Owing to its rarity, hydrogen possesses great buoyancy, in consequence of which it is used in filling balloons and dirigibles. It must not be inferred, however, that the lightness of the gas makes proportionally lighter bread. As a matter of fact salt rising bread is distinctly soft and close grained, resembling more nearly home-made bread than bakers bread.

The low density of the gases produced by the salt rising bacillus, coupled with the fact that no alcohol is produced, has an interesting economic significance. Scientific research has demonstrated beyond doubt that during the normal fermentation and baking of bread, appreciable losses occur. These losses, which have been estimated to approximate four or five per cent of the total nutrient value of the bread, owe their origin largely to the production of alcohol and carbon dioxide, both of which, on account of their volatility, are lost. In salt rising bread, these losses are less than one per cent. In consequence of this difference, salt rising bread is richer and sweeter than yeast bread, for the formation of alcohol and carbon dioxide signify consumption of sugar. This difference of three or four per cent in the bread yield seems a trifling matter when calculated on a bag of flour, but in the aggregate it sums up to a surprising consideration. Calculated on the Kansas wheat crop, for example, the possible saving is sufficient to cover the maintenance of both the university and the agricultural colleges.

The microbe flora in salt rising bread may vary greatly. Frequently *Bacillus coli commensalis* occurs in great numbers in the mass of fermenting dough. This or what is yet known, because of its association with typhoid and other diseases, renders water unfit for use. Yet the occurrence of this bacillus in bread is no cause for alarm, for it perishes in the oven. Furthermore, there is a sure way to prevent its ever occurring. Whenever the liquid used in setting the "sponge" is brought to a boil, *Bacillus coli commensalis* will never appear, for it does not form spores and hence perishes in boiling water. The salt rising bacillus discovered through these experiments, on the other hand, because of its sporulation, withstands this treatment. In the bread, however, even this bacillus, being in the sensitive vegetative state, always perishes in the oven. Hence, salt rising bread is as sterile as bread made with yeast. Why eat salt rising bread? This is a perfectly pat-

formity of bread from day to day. As the discovery of yeast by Pasteur led to revolutions in the manufacture of yeast and bread making, it does not seem unlikely that the discovery of this bacillus, which is an exact parallel, will revolutionize the manufacture of salt rising bread.

The idea of making bread with bacteria need seem neither dangerous nor distasteful. A bacillus may be more dangerous than a bullet, but not necessarily so. There are good ones and bad ones. Each species is specific in its action. They cause our most dreaded diseases, it is true, but they also make our vinegar, ripen our cheese, flavor our butter and tobacco, and hence no objection can be made to their raising our bread. How does this bacillus differ from yeast? Each

## A New Method of Educating Deaf Mutes

By Jacques Mayer

**D**R. MARAGE, celebrated for his many researches on the vocal and auditory organs, describes, in a communication presented to the Paris Academy of Sciences on January 18th, 1913, the principles of a new method of educating deaf mutes. Several years ago, Dr. Marage showed how the auditory faculty of deaf mutes and other deaf persons can be educated with the aid of a novel strain of his invention. In nearly every case he succeeded in causing the pupil to hear very simple vibrations, as a child hears the letters of the alphabet before he attempts to analyze words and phrases.

But the vibrations employed to reproduce the vowel sounds *O*, *U*, *A*, *E*, *I* (those of the English words *oot*, *oo*, *ah*, *get*, *fee*) although differing in duration, pitch and intensity, were alike in form quality or *timbre*. The pupil, having caught a vowel sound produced by the strain under a certain pressure endeavored to repeat that sound.

Dr. Marage has undertaken to complete his method by an appropriate training of the undeveloped auditory faculty in the perception of the more complex vibrations of speech. These vibrations (apart from the consonants, or supra-laryngeal noises, which begin and terminate the vowels) consist of the vowel sounds modified by compound vibrations, which represent the *timbre* of the individual voice and the defects in pronunciation.

In order to obtain the variation of *timbre* required for the application of his method of progressive education of the ear, Dr. Marage causes the notes emitted by the strain, before they reach the pupil's ear to traverse one of a series of buccal resonators, which are cuts of the human mouth in the positions which it assumes in pronouncing the various vowels. The *timbre* of the note produced by the strain thus modified varies with the pitch.

These variations can be traced in the records of vibrations which are shown in connection with the accompanying photograph of the strain. The first record (on the left) was made by vowel *A* emitted by the strain without the resonator. The strain was gradually lowered from beginning to end of the emission (from top to bottom of the record), but the vibrations preserve their original form, although the increase in intensity.

The second record was made with the same strain, emitting the vowel *A* with gradually lowered pitch, but the buccal resonator corresponding to the vowel *O* was interposed in the path of the sound. The trace of the vibrations varies continually in form and becomes more complex as the pitch is lowered.

The third record, made in the same way with the *O*U resonator attached to the *A* strain shows still greater variations. In each case the sound heard is the vowel *A* more or less modified, as if it were uttered by a poor speaker. With this apparatus and the various buccal resonators, therefore, it is possible to vary at will the four essential characters of the sound, pitch, duration, intensity and quality or *timbre*.

According to Dr. Marage, the auditory education of deaf mutes or the re-education of persons who have become deaf, requires the employment of aerial vibrations, such as those which the strain produces, in preference to the vibrations of metal rods or other instruments. The vibrations, furthermore, should be well known through preliminary photographic registration. The training should commence with very simple vibrations of one strain (*timbre*), representing the fundamental tones of the vowels, and should extend gradually to the more complex vibrations of variable *timbre* which occur in natural speech, the intensity of the sounds being varied from weak to weak in order to test the improvement in acuteness of hearing. In this way the auditory centers are awak-

Emerging from behind another vehicle, the driver can observe vehicles coming from the opposite direction and avoid possible collisions.

## Left Side Steer and Center Control in Motor Cars

By Howard Greene

**W**HEN automobiles first rolled on their uncertain and squeaky wheels over the roads that for so long had been sacred to the horse, they were built after a fashion that gave them every right to the appellation horseless carriages. In truth they were nothing like, for the simple reason that modeled after the only type of vehicle that was available as a pattern, they perforce embodied about as many of the characteristics of the horse vehicle as were not absolutely unnecessary in mechanical locomotion. What could be more natural, among other things, than that the driver should sit on the right hand side of the machine just as the driver always had sat on the right hand side of the carriage? It was a thing accepted without question and probably without thought—so much as a matter of course that only within the last few years has there been anything like a general appreciation of the fact that there are very good reasons why the chauffeur should steer from the left side of the car. Now however there are many cars in which left hand steer and center control are standard (and the tendency toward this arrangement of control is becoming unmistakably stronger).

There are disadvantages to right side steering that are of considerably more importance than might seem to be the case on first thought. When for example a car draws up to a curb in the way prescribed by law—that is with the right hand side of the car next to the sidewalk—a passenger sitting to the left of the chauffeur must get out into the road and walk around the machine in order to reach the sidewalk. In nine cases out of ten he cannot get out on the right hand side because he cannot pass the chauffeur and the steering wheel, and the chauffeur cannot pass the control levers. If the road is muddy or dusty the short walk around the car may be a very unpleasant one and, moreover, there is a considerable danger from passing vehicles, to say nothing of the possibility of being splashed with mud or enveloped in dust from their wheels. The chauffeur is no better off in this respect than the passenger in the front seat for except in the few cases where he can wriggle out between the levers he must ask the passenger to get out of his way or else climb over him. On the road with the car in rapid motion there is a phase of the right side steering situation that is more serious in that it involves more than mere discomfort. In meeting other vehicles, often also moving rapidly, it not infrequently happens that there is very little room to avoid them. The car may be in a street crowded with vehicular traffic or on a narrow country road where there is little opportunity to turn out. The chauffeur sits on the right, however where he is in the worst possible position to see just how many inches there are between the wheels of his car and those of the other vehicle. Obviously an error of judgment is much more readily made where the chauffeur cannot see than where he can and there is the possibility that both drivers may err.

It is argued in favor of right side steering that it is easy for the chauffeur to see just what he is doing when pulling up to a curb, and also that the right side position is the best when overtaking other vehicles on the road—all of which is more or less true. The ready rejoinder is, however, that experience has shown that there is little or no difficulty in making a good approach to a car steering from the left side after a little practice, especially as the curb is stationary and there is no particular necessity for speed. And when overtaking other vehicles on the road, no wise driver will speed up his car if there is no little room to spare that great accuracy of judgment is necessitated, usually the conditions are such that the overtaking car can choose the time for getting by, and so avoid complications. And in any case judging distance on the right

(Continued on page 252)

The gun being sighted at small elevation.

**P**RESENT tendencies in the construction of submarine boats are mainly toward an increase of their displacement. Moreover, in addition to the torpedoes carried in such boats, it is now thought advisable to equip them with defensive and protective ordnance.

In accordance with the special purposes of submarine boats, Messrs. Krupp have in this connection developed some special types of ordnance. In order to reduce as far as possible the water resistance in traveling below the surface, tapering-carriage guns of non-rusting, nickel steel were chosen in the case of small calibers. As regards, on the other hand, medium caliber guns, which on account of their size, would oppose a considerable resistance to the water, thus reducing materially the speed of traveling, means had to be provided for the ordnance to be stowed away during protracted voyages below the surface. These guns are designed for being got into fighting order with a few manipulations and in a minimum of time, after emerging from the water. A condition to be complied with in both cases then was to make any sensitive or disturbing parts (breach sights, shoulder rests, etc.) readily accessible and removable.

We present views of a gun of 75 centimeters caliber which comprises a sliding carriage intended to reduce the water resistance during submergence (traveling) is 500 kilograms in weight and while out of use rests in a hold below the upper deck. This hold is locked in a cover and when closed is only recessed from the slight projection of the stationary sliding support which does not oppose to the water any resistance worth speaking of.

In erecting the gun and turning it down the socket rotates round a bearing situated close to the front edge of the stationary socket. In order to erect the gun, the cover is opened and a bolt is loosened, after which the gun under the action of spiral springs, goes automatically into firing position. It is maintained in this position by resilient bolts. Twenty seconds are required to get the gun into fighting order and to attach the breech sight and shoulder rest, and the same time is occupied in removing these parts and stowing the gun away below deck.

The tube of the gun is fitted with a ram lock and is made of non-rusting nickel steel, so that it may be stowed away in a compartment which is not water-tight. The cradle surrounds the cylindrical part of the tube and rests with its two horizontal transoms in the bearings of the support. On the cradle is arranged the braking cylinder with the spring for restoring the tube into firing position. As seen from pictures, the tube, before being turned down, is pointed vertically upward, being maintained in this position by a spring. For this reason and in order to make the gun suitable for balloons and airplane defense, the upper part of the cradle support has been given a form allowing of considerable elevations. It may be said in this connection, that airplanes have already proved the most dangerous foes of submarine boats, if having been possible to sight from an airplane submarine boats traveling at considerable depths.

The pivoting socket has been given the shape of a column and carries at the top the bearing of the pivot. It is widened out in its lower part, so as to form a rest for revolving the gun and resilient bolts. The shoulder rest is pivoted in the gun in the case of small elevations. It is when used against the enemy's submarine boats, etc. In firing at considerable elevations, e. g., against airplanes the shoulder is turned round through an angle of 180 degrees. The breech sight comprises a panorama aiming telescope with automatically rotating objective prism head. The eyepiece is not moved in taking aim.

Firing is effected by means of a lever placed on the holder of the shoulder which is secured by the slider with the left hand, while his right hand takes hold of

**News From Mawson's Antarctic Expedition**  
THE Australian Antarctic Expedition, under Dr. Douglas Mawson, sailed from Hobart, Tasmania, in the ship "Aurora," December 22, 1911, for the purpose of exploring the great stretch of the Antarctic coast south of Australia, now usually known as Wilkes Land, extending from Victoria Land (the theater of Scott's and Shackleton's explorations) on the east, to Kaiser Wilhelm II Land (discovered by the "Gauss" expedition, in 1892) on the west. This coast includes several minor "lands" sighted and named by various earlier expeditions, such as Adelaide Land, named by Dumont d'Urville in honor of his wife, and the ever-problematical Termination Land, reported by the American expedition under Wilkes. The existence of Termination has been a subject of tedious discussion for a great many years. The matter may be disposed of by

Submarine gun at high-angle fire position.

saying that there is no such land in the place assigned to it by Wilkes, but assuming the possibility that that officer made a rather gross error in his observations of latitude and longitude, conceivable on the ground of weather conditions, he may have actually sighted the coast on which Wild's detachment of the Mawson party recently landed.

Mawson's expedition disclaimed any intention of pole-hunting. The party consisted mainly of graduates of the Australian universities, and was generously financed and equipped. Dr. Mawson himself is a well-known geologist and magnetician, and had previous antarctic experience with Shackleton, whom he was one of the three explorers who planted the Union Jack on the south magnetic pole. A radio-telegraphic station was established at Macquarie Island, and another in Adelle Land, where Mawson and a part of the expedition effected a landing in January, 1912. By means of these two stations it was hoped that communication could be relayed regularly between the Antarctic base of the expedition and the outside world, but only very recently have any wireless messages been received. After landing Mawson the ship cruised westward along the coast, and landed a second party, under Wild, at a point 1,200 miles from Mawson's station in February, 1912. The "Aurora" then returned to Hobart (about a year ago), bringing back the first detailed news of the progress of the expedition.

The ship proceeded again to Antarctica last autumn for the purpose of bridging back the two land parties. Wireless messages have now come through—apparently from Adelle Land—stating that Mawson and six of his companions were unable to join the ship, evidently owing to unfavorable ice conditions, and will be forced to spend another winter (i. e., the summer of our hemisphere) in the Antarctic. A message from Mawson himself says:

"Our sledging mission has been very successful. We have opened up a large area of new land both east and west of 'Commonwealth Bay' (where his party landed).

We have obtained important new data from numbers of stations in close proximity to the magnetic pole. The message also requests the royal assent to naming this new land King George V Land.

The expedition has unfortunately sustained the loss of two valuable members, viz., Lieut. B. E. S. Nilsen of the Royal Fusiliers, who was killed by falling into a crevasse nearly a year ago, and Dr. Xavier Mertz, a Swiss scientist and champion ski runner.

### The Current Supplement

**M. R. F. L. O. WADSWORTH** presents in this week's issue of the **SUPPLEMENT** the first part of the Preliminary Report made by the chairman of the Professional Committee to the Inventors' Guild—Prof. Herbert's inaugural address at the University of Leipzig, dealing with "Meteorology as an Exact Science," is reproduced in abstract.—Dr. David H. Day discusses "The Sky-scaper of the Future."—Mr. James H. Wain describes an extensive hydro-electric power project in California.—A cross-section of the horizontal part of a rocket is illustrated and described.—Our readers with aeronautic interests will find an article on the Benet flying boat, and a list of specifications of the requirements made by the U. S. Government for recent type military airplanes.—Of the highest interest is the report of a remarkable meeting of the London Chemical Society, at which papers were read by Sir William Ramsay, Prof. Collie, and Mr. Patterson, on an apparent case of the synthesis of matter. This is further discussed in a special article by Sir J. J. Thomson, who, as our readers know, has for some time past been working with a highly ingenious and refined method of analyzing gases. On another page we reproduce his latest report on his work.—A. Marsden tells us how individual atoms are made visible and counted.

## A Substitute for the Compass in Fog or Snow Storm

To the Editor of the SCIENTIFIC AMERICAN

As the result of a forced descent without compass from the observatory on Mount Rose (elevation 10,000 feet) in the heavy snowstorm of January 14th to 17th, the writer offers the following suggestion: persons who know the direction in which to start, but because of fog or blinding snowstorm cannot maintain the course with sufficient accuracy to reach their destination. However, two persons are essential to the carrying out of the plan, and snow is preferable to fog or sleet, because in the former any deviation is more noticeable.

Place the members of the party in a line forming the direction in which it is wished to go and sufficiently far apart, so that the man in the rear can observe enough of the trail made by the leader to determine whether it deviates from a straight line. If any deviation occurs, the suggestion "Right" or "Left" and "Steady" to the leader will be sufficient to bring him back to the course.

J. C. CARRAN, JR.  
Mount Rose Observatory, University of Nevada,  
Reno, Nevada.

## The Timing of Motor-boat Races

To the Editor of the SCIENTIFIC AMERICAN

I have been investigating the matter of timing motor-boat races, and have heard of many different persons who, in my opinion, know as much about the subject as anyone, but I have not been able to get many new ideas.

They generally agree on the plan of having some electronic communication between the mile posts at the start and the finish, and the preference seems to be for a telephone communication, because it permits of talking back and forth between the timers, enabling them to check their watches. They can also advise each other that such and such a boat is coming, get ready for timing, etc. I do not see much chance for improvement over this system, provided they have the installation.

If such telephone communications are not to be had, it seems to appear to me that the use of flags is the most reliable, as any discrepancy in timing by this method need not vary more than one fifth of a second. This is not likely to be of such serious consequence, except where an error of one fifth of a second might throw an important prize to one competitor before it really goes to the other. Even with the telephone system there is always a chance of the much error, and favoritism on the part of the unscrupulous judges.

It is not an easy matter to time a boat accurately that is starting at a point around fifty miles an hour, and the chances are that the boat would be a few feet either one side of the line or the other in taking the time. I like the idea of verifying the time by a photograph at the instant the time is taken, but this requires the perfection of apparatus which possibly would not be considered, and for that reason it is likely to be a useless suggestion.

In England, at the Isle of Wight, the Admiralty have a half-knot course for testing their boats. One course is up the river, and the other is in front of Osborne, in open water. Where facilities are not good for laying out to the mile or knot course, I think it would be much more practical to have the half-knot course. In Chicago, for example, such a course can be laid out on the Government breakwater, which runs in a straight line more than a half mile, and the motor boats can be timed as the boats can be run either outside or inside the breakwater, as desired. The advantage of the half-knot course is that flag signals would be very reliable.

In all cases fixed points, such as floating buoys, should be used, and I believe it would be a good idea if the man who calls time, or the man who sights the posts, had the vision of the approaching boat barred by a barrier of canvas or plank, so that he could not see the boat until it is actually finished at the line.

A still more practical scheme would be a funnel-shaped apparatus of any ten feet in length, this apparatus being mounted right on the line, so that the timer could look through it and sight the boat by two vertical lines or buoys in the telescopic sight. All vision of the course and the strong outside light would be cut off from the timer's eyes by means of a curtain such as a photographer uses in adjusting his instrument. The object of this funnel-shaped apparatus would be to give the timer a limited field of vision, and the tendency would be to concentrate his mind and thoughts on the correct timing of the boat as it passed the line.

Starting boats can be started as accurately as an automobile, and as races are usually held on water should be so to get up proper records. The tendency of the crowd to rush to a point to break an electrical connection (for

example, a string stretched across the course a few feet above the water, so that it would be struck by a short mast, the string not being more than three feet long) otherwise it would be interfered with by the wind, and the length would be so great that the time would be less correct. In this case the breaking of the string would operate electrical timing apparatus, and there would be no chance for errors of judgment or questions of favoritism.

Add to the methods and systems used in timing boats, the first important consideration is that the timing be done by some recognized authority, otherwise it will not have the value that it should have. It should be favor letting the American Power Boat Association have charge of all official timing of speed boats, and I believe that the sooner the motor-boat club of the United States and the people interested in the sport recognize some representative association and take an active management in the same, the sooner will we begin to make substantial progress, and motor-boat racing will not be the fiasco that it has been in the past.

The American Power Boat Association has recently adopted some restricted class race rule which I think will prove very advantageous to the sport. Those rules are along the line that I have been advocating and writing about for the past two years, viz., the establishing of class ratings on maximum cylinder volume, as has been found practical in automobile racing, and also in boat racing abroad.

The feature that I wish particularly to emphasize is that no timing system is worth considering, or of much value, if the timing is not done by officials of some organization of established standing.

New York City

## To Uphold the Merchant Marine

To the Editor of the SCIENTIFIC AMERICAN

In your editorial in the issue of January 9th you endorse the upholding of the American merchant marine in the deep-sea foreign trade by a return to the system that was in effect in the early days of the republic, i. e. the return of part of the duties to importers bringing their goods to the United States in American-built tonnage operated under the American flag.

This is only slightly indirect, and like all indirect measures, the benefits would not equal the disbursements, but the return to the American flag is a step toward to seek to do indirectly what is not allowed to be done openly.

One factor to be specially borne in mind in the application of differential duties in favor of American importers using American-built tonnage, is that every commercial treaty now in effect between the United States and foreign countries would have to be abrogated on differential duties could be put in effect.

This means a serious disturbance of business, and the way also is open to dishonesty and fraud and litigation, and the without taking into account that no mention is made of any benefit as coming to shippers generally.

It is not to be disputed that large concerns importing goods in large lots would find benefit in the differential duty system, but to the rank and file of importers there would be no resultant good. In fact, it is a question if they would not find themselves at greater disadvantage as far as ocean rates go by the differential system than they are today.

In the many theories advanced for upholding the American merchant marine, particular stress is laid on the benefits that shipyards and shipowners and labor employed in shipbuilding will enjoy. But shippers do not seem to be taken into account. There has been no mention in these various schemes where the American shipper will benefit in the way of reduced rates and better service. The argument is steadily advanced by the advocates of subsidy and differential duties that by these means the difference in the cost of American shipping and American operation of tonnage will be overcome, but nothing is said of lower rates. If all the American public is to get out of the change is to pay the same rate of freight and pay an additional tax to the support of American tonnage in the foreign trade, it is worse off in the last analysis than before.

We have one example of indirect aid to shipping now that would seem to be sufficient for the present: the American tonnage law. American tonnage is a duty on port trade between the Atlantic and Pacific. Free tolls to American overseas tonnage is nothing but an indirect subsidy, and there is not the slightest testimony that free tolls will reduce freight rates one iota, nor is there any evidence that it will stimulate the American tonnage industry, vessel that would not otherwise be built.

On the contrary, this short-sighted measure has been denounced in every section of the country, not alone because it is contended that it violates the Hay-Pauncefote Treaty, but because it is an indirect contribution to an industry already protected as few American industries are, and from which no resultant benefit flows to the body of the American people.

One of the things that hold back the development of the American merchant marine is the over-regulation of a steamer of the United States has to carry several more

men than does a foreign steamer, and it is not clearly shown what the benefit is. The American merchant marine is no freer from disaster than we will say the British merchant marine, and yet the cost of a voyage on an American steamer are much more onerous than on the British. Why the management of an American steamer is compelled by law to employ only Americans while the men that may be employed to build American steamers may be of any nationality is one of the things that is past finding out. Whatever the reason is the facts are there, and they add to the handicap that the American merchant marine suffers from.

And yet there is a ray of hope. The difference in the cost of building abroad in foreign shipyards is steadily lessening. To-day it costs to build in a British yard about \$40 per ton as against \$25 not so many years ago. The foreign shipyards are so overcrowded with work orders will not be taken for delivery till well into 1918. Here is an opportunity for the American builder. Why not try for orders from foreign shipbuilders? There is an urgent demand for tonnage. It is more than likely to continue for the next two years at least. The difference between the costs here and abroad for building the same type of steamer has narrowed down to about \$10 per ton. Perhaps some of our enterprising builders might out the difference still further. Isn't it worth the try? Especially as shipbuilding material is not on the free list, and the American shipbuilder is the first to feel the first effects of even footing, as far as the first cost of its material is concerned. As a matter of fact to-day British shipyards are inquiring for material in the United States.

There is no question that an American merchant marine would be a benefit to every American citizen, and if a plan is devised whereby the shipper, the laborer and the builder (in all benefit, there will be but little hostility in securing aid from the United States Congress. They would under present conditions be inclined probably, to consider paying subsidies to American-built ships operating to foreign countries, not adjacent to or on a basis that would generally equal the difference in the cost between the foreign-built and American-built ship, and in addition still further be paid to the American-owned foreign-built tonnage offered and manned by Americans and operated under the American flag.

All such steamships accepting subsidies should be forbidden to enter into agreements with foreign lines covering the right of call at ports of call, and the United States (Commerce Commission or some such similar body should have the right to pass on the fares for passengers or rates on freight, and to say that the same are fair and equitable, and to require of government aid should carry with it the right of government to regulate the rates.

Legislation for the aid of special industries is going out of fashion, if conditions are such that the assistance of the Government may justly be invoked then the Government should be asked to make the same for exporters and exporters as well as importers and shipbuilders will also be benefited. This desired result cannot be brought about by any such indirect means as differential duties, whatever the benefits in the early days of the republic. They would under present conditions lead to a practical monopoly in many lines of ocean freighting.

Foreign governments would counter in a similar manner in favor of their own tonnage. American importers that are able to supply steamers with full cargoes would pay practically all the benefit, and to the average American importer or exporter no benefits may be looked for as far as lower ocean rates are concerned. The upholding of the American merchant marine should benefit our manufacturers, exporters, and importers equally with shipbuilders. The American steamer trade should have the foreign markets that our growing manufacturing industries demand. The American merchant marine must be in a position to make lower rates in use of need than our foreign steamship lines.

Conditions are more favorable for the American shipbuilder than has been the case for many decades. The cost of the material to the foreign builder is constantly increasing, due to higher wages, to higher cost of ore, and to higher cost of coal, whereas the output of iron and steel is increasing at a tremendous rate, and it is true to believe that the cost of material will be much in favor of the American shipbuilder in a comparatively short time.

Our trade between South America and our countries is rapidly increasing, and it is not surprising that the American steamer line was the first to be established. There were American lines of steamers plying between South America and United States ports—fast steamers equal to, if not surpassing, the type of steamers that foreign steamship lines put on the service between South America and our ports. These steamers were fast, and as well as that, they were in goodly numbers, and we sought to aid them with adequate subsidy, but there should be no strings to government aid, it should be so broad that any American company wishing to engage in the ocean trade for carrying trade can seek the aid to be aid on equal terms and conditions. This has not been the case with any measure of government aid introduced into Congress in recent years, and this phase of the past subsidy bills did more to kill off the various measures than opposed to the principle of the aid.

Chicago, Ill.

CHARLES DERRICK.

# The Tallest Office Building in the World

## Erection of the Woolworth Building, New York

FOR the present at least the tallest office building in the world will be found on the western side of City Hall Park where the towering Woolworth Building lifts its glittering steel and terra cotta structure through a sheer height of 785 feet above the sidewalk. This is not only the loftiest office building, but, if we except the Eiffel tower, it is the tallest structure of any kind as yet erected by man. Two other notable buildings in this city, the Metropolitan Hotel and the City Hall tower, are next in height. The Metropolitan tower at Madison Square with a total height of just over 700 feet and the Singer tower, built like the Woolworth structure, on Broadway, and only a few city blocks to the south of it, which has a total height above the sidewalk of 612 feet. Mention should also be made of that remarkable structure on the opposite side of City Hall Park the New Municipal Building the top of the bronze figure with which it is now being crowned will be 520 feet above the sidewalk.

As the eye ranges up through the multitudinous stories of the Woolworth Building to the pyramidal structure at its top, the question arises as to what is the limit of height to which a habitable building can be carried. The answer is to be found in a certain restriction laid down by the Building Code of New York city which states that on a rock foundation the load may reach but not exceed 10 tons to the square foot. It will surprise some of our readers to learn that on this basis, it would be possible on a plot of ground 100 feet square to erect an office building 2,000 feet in height and to build it moreover, so that it would be perfectly secure against the fiercest hurricane, and, because of its elasticity even against the altogether improbable event of an earthquake shock.

### Some Dimensions and Quantities.

The Woolworth Building is taller than it looks. To reach its lowest foundation, we must go down in one place to a depth of 120 feet beneath the sidewalk - for that was the depth to which it was necessary to sink the pneumatic caissons in the soft mud before the solid rock of Manhattan Island was reached. This would make the total height of the building from low est foundation to summit 905 feet. Just here while touching on the question of dimensions and quantities we may state that the building contains 2,000,000 cubic feet of structural steel, 17,000,000 cubic feet of brick 7,500 tons of terra cotta, 1,800,000 square feet of floor tile, 1,000,000 square feet of partition tile, and 2,500 square feet of cut stone.

The construction of the foundation also involved 10,000 cubic yard excavation, the use of 24,000 yards of concrete, 400 tons of reinforcement steel and 550 tons of steel sheet piling. Finally, the building which with its furniture, etc., will weigh more than 1,500,000 tons will have cost, when complete, some \$23,000,000.

The building covers a plot 105 feet by 200 feet. It is L shaped in plan, with two wings 60 by 105 feet, facing on Barclay Street and Park Place. The shorter side of the plot is that on Broadway. There are thirty stories in the main building, the roof of which stands four hundred feet above the street. From the center of the Broadway facade and flush with it rises a tower measuring 80 by 80 feet, which extends for the additional twenty five stories above the roof. The building is carried on 90 concrete piers, sunk through gravel, sand and hardpan, even here to a depth of 120 feet where it was found at an average depth of about 40 feet below the ground water level. These foundation piers are of solid concrete. The majority are circular and vary in diameter from 8 to 10 feet. A few of them are of rectangular cross-section.

Until the hardpan was reached, the sinking of the caissons was quickly and rapidly done and one, 6½ feet in diameter went down 80 feet in less than a single day.

### Erecting the Steel Frame

Although the vertical axes of the majority of the columns coincide with the axes of the concrete piers below them this is not always the case. Several of the columns are supported upon two piers, the piers being joined by girders with the columns resting at their feet. The distance between the centers of the piers is 10 feet. The load is carried at a center of a girder 8 feet deep, 8 feet 6 inches wide, and 25 feet long which is 10½ inches over one hundred tons. Ordinarily between the pier and the foot of the column is a giraffe of section 11 ft. 21 in. by 10 in.

Naturally the columns in a building of this height run up enormous dimensions and weights in the lower stories. Usually they were built in two-story lengths, and were of entirely inclosed box section, consisting of two channels with cover plates in both flanges. The largest column measures 34 inches by 30

inches, and its cross-sectional area is 600 square inches, that is to say, the metal in it, if compressed into a solid square bar, would measure 26 inches on each side. It is easy to understand from these dimensions that the total weight of the structural steel reaches 23,000 tons.

### To Resist Wind Pressure.

When it is borne in mind that the storms which sweep across Manhattan Island, chiefly from the west and southwest rise at times to a cyclonic force and blow at a velocity of between 80 and 90 miles an hour it can be understood readily that special provision had to be made, in designing so lofty a tower, to safeguard it against overturning or against failure in its steel frame due to enormous bending stresses engendered. It is considered that for a building of this magnitude

Operation of the air cushion safety stop.

it is sufficient to estimate the average wind pressure, at maximum velocity, as 80 pounds upon every square foot of surface exposed. If we disregard the shelter afforded by the low buildings at its base, we find that the total wind pressure from top of tower to sidewalk over the whole surface facing a westerly wind is 1,800 tons, and this pressure may be considered as concentrated at a level of say about 200 feet above the sidewalk. It is evident, at once, that in order adequately to take care of this wind load, special features had to be introduced into the design of the steel framework. The inclined steel rafters of the spine-like roof of the tower take care of the horizontal thrust of the wind. Below the roof for the forty-second floor, the wind struts are provided for by the wall girders and the columns, which are connected by deep gusset plates at their intersections. From the forty-second to the twenty-eighth floors, deep wall girders, made especially heavy for the purpose, are connected to the columns by double knee-braces. From the twenty-eighth floor to the street, heavy solid plates of steel, or "portals" as they are called, are constructed on the two sides and top of each

opening or panel in the steel work. It was these portals that gave an appearance of enormous width to the columns between they were closed in by the terra cotta and stone work. On the Broadway front the portal girders are double as far up as the fourth floor, and they are no less than four feet in depth.

### Fireproof Construction.

The floors of the basement and first story are built of reinforced concrete slabs, and the floors above of hollow terra cotta. The structural steel is protected against fire by a coating of concrete not less than one inch in thickness, or else by 3 inches of terra cotta. Wood as a material of construction is entirely excluded, the windows, the trim, the doors, are of pressed steel, and furthermore, the exterior windows where exposed are glazed with wire glass. In addition to the twenty-six elevators there are four wide stairways. A description of the installation of steam heat, ventilation apparatus, plumbing, drainage, gas and electric light pneumatic service, etc. would make a long story by itself.

The building was commenced in September, 1910, and it is today practically ready for occupation. The rate at which the building was carried up is shown in the accompanying set of illustrations, which were taken from a lofty building on the opposite side of City Hall Park.

### Safeguarding the Workmen and the Public.

An interesting feature of the construction of the Woolworth Building was the fact that the advanced ideas that underlie modern liability insurance were exemplified in an interesting manner, the inspection service rendered during the work being particularly worthy of note. The insurance company that carried the liability risk sent two inspectors on duty continuously, and immediately upon noting a condition which was likely to result in an accident, they notified the proper foreman or superintendent, and saw that the danger was removed. Their recommendations were also reported to the office of the department of safety, a special division of the insurance company, and written copies were then sent to the contractors.

Patent scaffolding was used for the brick laying throughout the work, and these were covered, so far as possible, with canvas, so that the men at work upon the platforms from tools and materials that might fall from above. The sides of all the scaffold platforms were also protected by guard rails and by wire-mesh screens. Substantial bridges for the protection of pedestrians and others were built over the sidewalks, and these were made stout enough to resist the impact of any material that might fall upon them. Platforms 30 feet wide were also built out from the building at four different heights, to catch any material that might fall, and prevent it from descending into the street. Wire-mesh screens were arranged along their outer edges to give still further security.

All the hoisting apparatus was examined frequently and thoroughly by expert elevator inspectors, employees were not allowed to ride on material hoists, and the maximum number of persons who might be permitted to ride on a passenger hoist was definitely specified in each case. All hoists, whether used for the transportation of men or of materials, were covered overhead with a chain of small links. The hoist openings were effectively fenced, and were guarded by rails where the materials were loaded or unloaded. Openings in the floors were thoroughly guarded by rails or fences or otherwise. All stairways, whether inside or outside, were thoroughly guarded by rail guards. Proper lighting was installed upon, particularly at work places, along gangways and passages, and at every other important point. Warning signs were put up at all dangerous places. Laborers engaged in outside work and persons who were required to be on the sidewalk were obliged to use electric bells with portable handles, so that their own hands would not be injured if the strikers should make the heads of the chains. An effective watch was kept for nails and other similar sharp metal points projecting from the woodwork or from loose planks or boards or elsewhere. These are prolific sources of injury, and the men were required to remove them at once. First-aid cabinets were also provided, at the suggestion of the liability inspectors.

It was apparent that the comparative freedom from accident that characterized the erection of the Woolworth Building was not the result of chance, but that it was the logical outcome of the practical system of inspection that was adopted.

### A Remarkable Horizontal Tour.

The express elevator of the Woolworth Building

have a vertical travel of 976 feet, and Mr. W. T. Ell Thorpe, who is responsible for the safety system provided for the twenty-eight elevators, will make that sheer drop to demonstrate that his apparatus is equal to the maximum stress to which it may by possible mishap be subjected in service. What is technically known as

an "air cushion" will first check the car and then bring it to a gentle halt. From the bottom of each shaft upward for a distance of 157 feet the passageway is inclosed, forming the envelope of the so-called "cushion." Of course, there are doors at each floor but these are closed mechanically as the elevators pass on-

ward. The broad essential is that the surrounding casing shall be substantially air tight and that there shall be no escape for the air except upward past the sides of the descending vehicle. For the major part of its travel down this inclosed shaft, the space be-

THE TALLEST OFFICE BUILDING IN THE WORLD.

# What is Matter?

## The Individual Molecule Revealed

*To observe the infinitesimally small, we must impart to it proportionally intense properties. Thus Sir J. J. Thomson shoots molecules with a muzzle velocity of 12,000 miles per second from an electric gun with a two-hundredth inch bore and from the pattern at the target deduces the mass of a molecule of which five thousand million million millions make a drop of water. Molecules possessing a very high velocity are also known to us in a particles shot out by radium, which Sir William Ramsay has proved to be molecules of helium. His latest contribution to science seems to point to the building up of the atom the synthesis of matter.—Fulton.*

### Has Matter Been Synthesized? An Account of Some New Experiments

By J. W. N. Sullivan

THE immense amount of work which has been done on the radioactivity substances has rendered familiar to us the notion of the disintegration of matter. We know that the last elements of the periodic table these possessing an atomic weight between 230 and 240, are not entirely stable but that the heavier elements are gradually changing into others of less atomic weight. These elements disintegrate at very unequal rates, so that the element uranium takes 7,600 million years to change into the element radium while the average life of radium is only 2,300 years. And the extraordinarily active substance known as radium emanation lasts on an average for only 5.5 days. It is probable that the final stable form assumed by uranium in its successive disintegrations is lead, and that it passes through about thirty intermediate forms before it reaches this stage.

It is an extraordinary fact that we find helium almost invariably associated with these changes. Helium whose atomic mass is 4, is a monatomic gas and is completely inert forming no chemical compounds. Neither is it chemically absorbed by any substances whatever and of all gases it is the most difficult to liquefy. Nevertheless, this unobtainable, unabsorbable gas was first found on earth (it had been known for some time to exist in the sun) in certain minerals which also contained uranium and thorium. This fact in conjunction with those furnished by our study of the radioactive substances in detail leads us irresistibly to the conclusion that helium is one of the ultimate products of the spontaneous change of the elements. These phenomena of disintegration naturally raise us to ask: Can the converse change occur in nature? Can matter be synthesized and the heavier elements built up by suitable operating upon those of less atomic weight? We seem now to be in a position to give an affirmative answer to these questions.

On February 9th at a meeting of the Chemical Society in London Sir William Ramsay read a paper on "The Presence of Helium in the Gas from the Interior of an X-ray Tube" and Prof. Collie in conjunction with Mr. Patterson read their paper on the presence of neon in hydrogen after the passage of the electric discharge through hydrogen at low pressures. Sir William Ramsay on breaking old X-ray tubes and analyzing the gases contained in the glass had found helium neon and argon the last named gases being two of the rare constituents of the atmosphere. Last November, instead of breaking the bulbs, he had strongly heated them which again by spectroscopic analysis, he had found helium and neon. So far the evidence is conclusive that helium certainly exists in old X-ray tubes, but when we discuss the origin we are confronted by difficulties. In working an X-ray tube numbers of electrons are continually being shot out from the cathode. It is indeed the sudden changes in velocity as perceived in these minute bodies when they come in contact with the walls of the tube that give rise to the X-rays. It is possible therefore that helium and neon X-rays in minute quantities in the cathode or the anti-cathode or in the glass of the tube, and that the violent bombardment of them by the electrons sent the gases free. A further experiment of Sir William Ramsay's was to treat water with radium emanation. It was ex-

pected that helium would be found but actually neon was obtained. The atomic weight of neon is 20, and this suggests that it was formed by a combination of helium, whose atomic weight is 4, with oxygen whose atomic weight is 16. This suggested combination is borne out by the extremely interesting experiments of Prof. Collie and Mr. Patterson.

Mr. Patterson had thought that by doubling the charge on a hydrogen atom it might be possible to produce an a particle such as is shot out by radium and is known to be helium. But on sparking the hydrogen he perceived neon.

The possibility suggested itself that this neon came from the outside air the glass vessel conceivably allowing it to pass under the action of the electric bombardment. But on surrounding the tube by an outside vessel containing neon, and then heating, the same results were obtained as before. Further, the condition of affairs was not altered when the outer surrounding vessel was tightly exhausted so as to form an almost perfect vacuum. The neon still appeared in the inner tube in perceptible quantities. But the most startling discovery was made a few days before the meeting of the Chemical Society. Prof. Collie decided to test the outer highly exhausted chamber to see if there was anything in it. On letting in a cubic centimeter of oxygen there was a slight explosion, due to hydrogen. The oxygen was absorbed in the usual way by carbon but it seemed impossible to completely absorb it. On testing this residual gas by turning on the induction coil the tube was found to be ablaze with helium, with some neon mixed.

Mr. Patterson made the experiment and found helium in the outer tube, but on varying the experiment by first filling the outer tube with oxygen, he found neon there. But that we are again led to look upon neon as being formed by a union of helium and oxygen. It would seem that the helium formed by the passage of the electric discharge in the inner tube has sufficient velocity to penetrate through the glass walls into the outer chamber and to combine there in some way with the oxygen to form neon.

If the helium in the inner tube is formed from the hydrogen, we may obtain some idea of the mechanism of this change by recalling some of the fundamental notions of the electron theory. On that theory the atoms of all elements are made up of systems of electrons, the electrons being in a state of rotation according to certain laws. If now one of these complicated systems be struck by a free electron, moving with a velocity comparable to that of light, such as are produced in numbers in a cathode tube, we should expect something in the nature of a catastrophic splitting up of the original system, and the subsequent recombination (we might assume another of the standard forms which we call elements. Some time ago Sir J. J. Thomson published a very interesting investigation showing the way in which the various elements might be formed by appropriate groupings of their constituent electrons, and accounting for many of their chemical properties by this hypothesis.

Although the synthesis of matter is theoretically possible, yet when we actually try to impart a result has actually been obtained, we must exercise a due amount of scientific caution. Thus the investigators whose work we have been describing point out that the gases found may have been originally present in the glass of the vessel or in the electrodes. However that

may be, it is certain that in previous experiments of this kind, it has ultimately been found that such has been the case. Sir J. J. Thomson, whose supreme eminence in this class of work cannot be questioned, is of the opinion that nothing further has been done in these new experiments than to liberate the gases already contained in the apparatus, and he points out the extreme difficulty of successfully eliminating these gases before subjecting the tube to the electric bombardment. He had himself, as a result of his own experiments, believed for some time that he had discovered a new element of atomic weight three, obtained from the hydrogen in his tube but subsequent investigations had proved that this idea was unfounded. [Sir J. J. Thomson's present view is that this substance is a polymerized form of hydrogen, as explained in an other article on this page.—Fulton.] Sir Oliver Lodge and Mr. Soddy are also inclined to think that the new experiments do not differ essentially from others in which observers had mistakenly supposed that they had accomplished the synthesis of matter. So that we do well to be cautious. Science differs from other human activities in the superior quality of the evidence that it produces for its assertions, and it is a point of honor with a scientific man not to believe easily. But whether future investigations confirm or refute the claim that matter has been synthesized, the new experiments have greatly aroused the interest of intelligent men and directed attention to matters which are usually ignored, and in that respect at least have done science a service.

### In the World of Molecules

By Alfred J. Leake, M. A., D.Sc.

MANY hundred years ago a Greek philosopher made an acute guess, that matter is composed of small particles, so small as to escape the direct observation of our senses, but themselves not further divisible atoms. Centuries have elapsed, and it was reserved for this generation, not only to prove the existence of the atoms, but to weigh them and to count them one by one. (It should be remarked, however, that the typical atom is not incapable of further subdivision, according to the present state of knowledge.) What an exquisite achievement of scientific genius this represents, the reader may realize when he calls to mind the order of magnitude of some of the dimensions involved. It is almost useless to quote figures, as the mind fails to comprehend the immense ratios involved. A graphic example is more helpful. If a drop of water were magnified to the size of the earth, the molecules in it would be of the size of foot balls.

How, then, has the physicist succeeded in measuring, weighing and counting these minute particles, utterly beyond the reach of the ordinary microscope, whose power is exhausted in detecting structures some thousand times greater in linear dimensions than a simple molecule? Even the ultra-microscope, against the limit of visibility only a little farther, perhaps about fifty times smaller than those discerned by the microscope, as exhaustive answer to the question, must be given here. For details the reader is referred to the splendid articles by Streeter, Aston, and others, which have appeared in recent issues of the SCIENTIFIC AMERICAN SUPPLEMENT. We must content ourselves here to pick out one or two points of special

**Interpret** How has the physicist accomplished the stupendous feat of counting individual molecules?

Bottom, which, fifteen years ago, came upon the scene of physical science, holds the key to this, as to so many wonders of modern science.

If the atom of helium is small, it possesses a terrific velocity when shot out (as an a particle) from a radium molecule undergoing disintegration. Such an atom, moving at the rate of 12,000 miles per second, a speed which would carry it from the earth to the sun in the space of two hours, is allowed to impinge upon a screen of thin blende, where it produces a visible flash of light, a scintillation as it is termed technically. This fact has been made use of in counting helium molecules.

But the art of the physicist does not stop here. He is not dependent on the bounty of nature for his supply of rapidly moving molecules. Mr. J. J. Thomson in his monumental researches, has taught us how to train a miniature gun at a target and shoot molecules with one tenth the speed of light. Charged molecules moving at such speeds behave like electric currents, and, like these are deflected by a magnetic field. The amount of this deflection, and of the deviation produced by an electric field, enables the observer to determine the mass of the molecule. The unknown, as it were, is made to weigh itself, and to register its weight on a photographic plate.

No wonder with such methods as these that Mr. J. J. Thomson is reaping a harvest of remarkable new discoveries. The delicacy of the process is such that by its means quantities of helium for example, which the spectroscopic fails even to reveal, are not only detected and identified but are made to register their atomic weight. (The quantity of substance required is about one hundredth of a milligramme or about three millionths of an ounce.) Only the chemist, who knows the intricacies and tedious labor involved in an atomic weight determination by ordinary methods, can fully appreciate the significance of this. The chemist too, who presently learns to appreciate the value of a method which enables us to deal with molecules or radicals having a brief life of one ten millionth part of a second. It may perhaps appear at first sight as if a substance of such short duration could not possibly ever gain any practical interest. But it must be remembered that in every chemical reaction matter must pass through transient stages intermediate between two compounds. While the existence of such evanescent states of matter has been more or less vaguely realized and has been clearly referred to by specialists, for example the chemist using the ordinary established methods of work was utterly incapable of even approaching the study of these transient states of matter.

Fig. 3.—What is the form of the central white band in this drawing? Try it out with a ruler.

Fig. 4.—What is the relative length of the horizontal line in the four figures above?

which is not yet fully explained is that of a substance having molecular weight 8. It is difficult to explain this in any other way than by attributing it to triatomic hydrogen  $H_3$ , although no such substance had hitherto come under observation. The gas has been obtained by submitting various materials to cathode ray bombardment, and Mr. J. J. Thomson inclines to the view that it is originally contained in these materials (aluminum, platinum, etc.) and is in some way released by the bombardment. These observations have quite recently acquired

Mr. J. J. Thomson's latest report on this subject, a lecture before the Royal Institution, is reproduced in this week's *Scientific American Supplement*, to which the reader is referred for details. He will there find also some very significant comments by Mr. J. J. Thomson on the work of Rutherford, Curie, and Perrin, while another chapter in the same issue discusses the experimental arrangement employed for observing the "scintillation" induced by alpha-rays.

particular interest through the publication of a paper by Mr. William Ramsay, Prof. Curie and Mr. Perrin, who have obtained evidence of the apparatus for isolation of helium and neon under remarkable circumstances. It may be that these gases are present in reality and are merely released under the conditions of the experiment.

### Optical Illusions; Trust Not Your Eyes

**THINK** is an old proverb. "Seeing is Believing" is like many old sayings, it is far from being fully justified. We believe and judge, in the existence of many things that we do not see such as for example molecules, and what is at times even more important, we cannot always trust unerringly to the accuracy of plain evidence of our senses. How very much we are subject to error of perception and of memory has been well brought out by Prof. Münsterberg among others, in his well known popular exposition "On the Witness Stand." But even a mere sense-perception, quite apart from tricks played on us by our deficient and deceitful memory, may be deceiving to an almost unbelievable extent. Various "optical illusions," as they are called, have long been known and we reproduce herewith several.

By courtesy of Dr. Münsterberg.

Fig. 1.—A pattern made up of oblongs? No, concentric circles!

Fig. 2.—A spiral which is not a spiral. What is it?

and classical examples, together with two or three of more recent origin which surpass all others in their convincing power.

Three of the illustrations shown here belong to one type: In each case the optical illusion relates to our own angles. Thus, in Fig. 1 the horizontal lines appear best converging at their ends. As a matter of fact, they are perfectly straight and parallel. A similar effect is produced in Fig. 6 by the cross hatching, which gives a spurious appearance to a set of parallel straight lines. In Fig. 7 you are asked to trace one line  $ab$ , which is partly covered up. Is it straight, or is it curved? Answer the question

By courtesy of Dr. Münsterberg.

Fig. 5.—In selecting material for a garment it is well to consider the deceitfulness of appearances.

Fig. 6.—The long lines appear to run in a zigzag. You may not believe they are parallel until you have measured the space between them.

Fig. 7.—A "straight" line which is not a straight line, and one which is.

by eye, then try a ruler to prove your answer. A somewhat different type of illusion is illustrated in Fig. 4. In this case it is the length of a line which is deceptive. Of the horizontal lines in the four parts of this figure, which is the shortest, and which the longest? Measure them with a ruler and see.

But of all optical illusions the most convincing are those shown in Figs. 1, 2, and 5. Do you see the spiral on the right, Fig. 2? Well, it is not a spiral but a set of concentric circles! Do you not believe it? Get out your compass and try. As for the figure on the left, how would you describe its pattern? Now what the compass may show!

Our last illustration may appear somewhat frivolous. We might draw from it the practical lesson that it pays to consider the effect of the position of your trousers if you are vain about the shape of your legs.

### Scott's Motor Sledges

**IN** a recent number of *The New York Times* is discussed the sledge that Scott took with him on his ill-fated antarctic expedition. Day's account is interesting because he drove one of the sledges. Moreover he had previously been in charge of a motor sled with Capt. Shackleton's expedition of 1907 to 1909.

Scott took with him two motor sledges each capable of carrying two tons. Mr. Day states that the sledges covered one hundred miles over soft surfaces upon which melted from two to eight inches of snow. The top of this surface seemed to have the consistency of sand rather than of snow at very low temperatures. The sledges were driven by 14-horse-power air-cooled engines with the cylinders cast in pairs. Mr. Day states that the engines worked splendidly, although Scott himself stated in a paper sent to civilization long before he made his dash for the pole that they were stalled because of the overheating of the engines. It may be that they were repaired after Scott undertook his expedition. For Mr. Day says that the four pairs of cylinders were kept comparatively cool by a fan, which was, however, supposed to keep the whole engine cool the heat being conducted down through the connecting rods to the big ends, which finally crumbled to pieces. This trouble Mr. Day attributes to the great mass of snow which was piled up in front of the sledges, and to the engine caused by the nature of the surface over which the sledges had to travel. The heat however did not melt out the white metal. On examination the phosphor bronze was found to have become crystallized and had apparently fallen in pieces, as shown in the drawing which was subjected to low temperatures and undue strain.

The carburetor was a source of anxiety. To keep the snow out when blizzards were ruling Mr. Day had to make a bonnet for each engine, and this bonnet had to be opened up while the engine was running. Consequently cold air entered the carburetor if the wind happened to be on that side and thus the gasoline would not vaporize. When the engine in fact the bonnet would be shut down and the engine would run hot. All this happened in spite of the exhaust jacket around the carburetor, but the jacket must be mentioned did not surround the choke valve. The fact that an engine which did not run hot in Norway run hot in the Antarctic regions may be attributed to the intense dryness of the southern atmosphere.

In a dispatch published in the *New York Times* Commander Evans states that Scott and his companion after having determined that they were within half a mile of the pole marched on to the desired spot talking with them their motor sledges and then plant of the Union Jack. Can it be that Scott had underrated the motor sledges in his earlier accounts?

### Buying Oil in Original Packages

**H**OWEVER, it is thoroughly

to be expected that the mechanical construction of his car, the automobile, and the mobile use parts but scant attention to the matter of lubricants. He has even heard which advertised brands of oil and trusts to the honesty of the purveyor. He keeps that the oil asked for is supplied. While the better class of dealers give the

demanded, the temptation to substitute is unquestionably yielded to by the less scrupulous. Just as some wine dealers supply different varieties of wine from a single cask, so the dishonest automobile supply dealer or garage keeper sells many different brands of lubricants from a single barrel. Since motor oils are alike in color it is difficult to identify the lubricant thus supplied. The motorist's best safeguard is to follow the practice of wise housekeepers of buying, only in original packages. Practically every known trademark brand of oil is sold in barrels, bladders, and in gallon tins. The same is so on the continents, and in most cases the containers are sealed. Unless the motorist buys in these original packages he has usually but little assurance that he is getting the oil he asks for. Therefore, the trade-marked and labeled tin is to be preferred in most cases.

Simple Patent Law, Patent Office News; Notes on Trademarks

## A New Tire for Motor Trucks

By C. Francis Jenkins

A motor truck construction, the tire problem has yet to be solved. Motor, transmission and steering gear have been worked out to a practical basis, but tires do not wear correspondingly. The life of the solid rubber motor truck tire is so short that tires cost more than all the other running expenses added. The tires do not wear out, they simply go to pieces under the pounding of the cobblestone streets. And the thicker the rubber the greater the loss. For this reason thin tires are frequently recommended for heavy trucks, rubber being employed at most sparingly.

If therefore something can be found which will give as good traction as rubber, cost less and wear longer, it will merit serious consideration and extended tests. Wood seems to fulfill these conditions admirably, and no tests of wooden tires were undertaken.

Wood is proving its good qualities in similar service, i. e., in street paving, ferryboat and warehouse flooring, and such other surfaces as are subjected to excessive attack. It has been so in use for a long time, and has proved superior to other materials, especially in its excellent adhesive qualities. Its surface does not become slippery in wet weather.

These qualities, i. e., good traction and long wear, recommend the use of wood as a truck tire, and at first the question seemed simply a matter of selection of the suitable wood. After a long search and much experimentation a wood was found which seemed to lend itself admirably to this service. And it could be had in sufficient quantities, and, fortunately, is not very suitable for anything else. It is close-grained yet soft enough to make it practically noiseless, and so tough that it cannot be split with an ax. The grain of the wood runs toward itself in the tough end grain of the wood and provides most excellent traction as good as solid rubber in dry weather and a thousand times better on a wet street.

There was one initially insurmountable difficulty, however, the tire would expand when it got wet and then when it dried out again the blocks would separate and the tire would go to pieces. The contraction and expansion would make it sure, but it was enough to ruin the tire. This difficulty was finally overcome by the very simple expedient of imbedding in the tire a powerful spring band either a heavy spiral spring entirely inclosed in the tire, or stannous flat spring bands located in a shallow groove in the tread of the tire. The blocks which constitute the tire are dovetailed together laterally including the spring band, and then after being thoroughly dried the tire is placed in a vacuum chamber and impregnated with a water repellent.

Such a construction makes the tire in general and capable of being handled shipped marketed and used as convenient as a rubber tire. They should, of course be made in all standard sizes and in such widths of tread as may be required by the loads to be carried.

Thus apparently an entirely satisfactory tire for motor trucks has at last been evolved. A tire made up of blocks of wood set like street paving blocks, with the grain cut on to the point of attack that is with the grain of the wood radial to the wheel, and having a powerful spring band imbedded in the tire to hold the blocks in place and compensate for longitudinal contraction and expansion. It is easily and quickly secured in place on the wheel, the driver simply unbolts the old rim, throws away the worn

out tire, and replaces it with the new tire. These tires will travel over softer ground, last many times longer than solid rubber tires, and cost but a small fraction as much as a rubber for the same loads. They are noiseless, and give better traction and do not skid on wet pavement. At first it was thought that per-

Wooden tire showing peripheral spring band.

Wooden tire, made of blocks and fitted with demountable flanges. In center is a cross-section of tire, showing imbedded springs.

Wooden tire before flanges are applied. It is set with the grain end-on, that is, the grain of the wood is radial to the wheel.

An electric meat slicer fitted with an automatic knife sharpener

The Timmer engine, showing the method of feeding fuels of different types.

## An Automatic Sharpener for an Electric Meat Slicer

By Frank C. Perkins

THIS accompanying illustration shows a novel automatic meat slicer which is operated by either an electric motor or by hand, and is an efficient labor-saving device.

The first useful slicer was invented in 1900 by Mr. W. A. Van Borkel, a practical butcher of Rotterdam, Holland, and this machine was a great advance on the old method of slicing by hand knife. After a time, as with most inventions, experience proved that the machine was not a perfect proposition as one of the most important defects was the impossibility of keeping the knife sharp enough to prevent loss of waste meat due to damaged slices.

The secret of the successful working of this new slicer with an automatic sharpener is in maintaining a keen edge on the knife all the time. The automatic sharpener is an ingenious device in it ways ready for use and is operated by simply turning the handle of the machine. The work is done in a few minutes. It keeps the knife in perfect condition, and is readily adjusted to take up wear. It saves time and labor and abolishes the risk involved in the use of the old hand stone.

A knife guard is provided which prevents the operator's hand coming in contact with a knife, and it is so arranged that the user cannot cut himself. Hence is far safer to handle than the ordinary hand knife.

Should the electric motor be out of commission the slicer can be converted to hand power in a few seconds. The electric motor is belted to the slicer from below the counter, the slicer being fitted with intermediate gear for use in speed reduction.

## An Engine That Will Run on Several Fuels

THE present high price of gasoline and the probability of still higher prices in the future have brought the fuel question into such prominence that more than ordinary interest attaches to any plan that promises relief or suggests possibilities in the way of lowering construction and operation costs.

Whether or not the motor designed—or to speak correctly converted—by I. C. Timmer of New York is all that is claimed for it in the way of a consumer of heavy oils of almost any kind, remains to be proven by actual commercial service in the hands of disinterested users. In the mean time one motor now is running to demonstrate the principles involved. It is in the hands of the inventor, however, who cannot, even if he would, handle the engine as a stranger would handle it. That there is much that is of interest in the engine, however, may be gathered from the fact that it runs on various hydro-carbons ranging in density from gasoline and crude oil to gas house tar without other adjustment than the changing of the feed valve opening, that there is no special fuel feeding mechanism, such as a pump, pressure system or spraying device, that there is no cooling system, either air or water, and that though there are no rings on the piston there is apparently no more loss of compression than in an engine with a ring-packed piston.

The Timmer engine is an old-fashioned machine of the vintage of the days of hot tube ignition, with certain alterations in more or less important details. It operates on the straight Knorr-Otto principle.

world, who assist in the prosecution of patent and trade-mark applications filed in all countries foreign to the United States.

The Editor is always glad to receive illustrations and photographs on subjects of timely interest. If the photographs are stereoscopic, please send both parts enclosed. Send also a brief description of the subject. Accepted articles will be paid for at regular rates.

The purpose of this Journal is to record accurately, simply and interestingly, the work of progress in scientific knowledge and industrial activity.

## The Minority Views on the Oldfield Bill

In their excellent written report on the Oldfield Bill six of fourteen members of the House Committee on Patents have expressed their minority views on the fully of legislative compulsory license and of extending the right of a patentee to treat license violations as patent infringements. Not only are the defects to which we have previously called attention needlessly exposed, but others are revealed which we now hasten to show and rectify. The Oldfield Bill was framed to cure "evils" which do not exist.

In the proposed introduction of compulsory license and in the limitations intended to prevent the patentee from fixing the price at which his invention may be sold or from prescribing the manner of its use, the minority members see nothing but danger. Compulsory working clauses are to be found in many of the European statutes. Not only are the European industrial conditions different from ours, but it seems to be the consensus of opinion that the compulsory work of the kind of foreign countries is a bad thing. Compulsory working clauses are to be found in many of the European statutes. Not only are the European industrial conditions different from ours, but it seems to be the consensus of opinion that the compulsory work of the kind of foreign countries is a bad thing. Compulsory working clauses are to be found in many of the European statutes. Not only are the European industrial conditions different from ours, but it seems to be the consensus of opinion that the compulsory work of the kind of foreign countries is a bad thing.

Even if the compulsory license principle could be successfully grafted on our patent system, the minority members of the Committee point out how impossible it would be to carry out Representative Oldfield's provisions and still do justice. No remedy has been framed that it contains no provision to permit the intervention of a licensee in an action brought to compel the granting of a license. Hence a licensee might be kept in complete ignorance of a proceeding in the outcome of which he is vitally interested.

Equally reprehensible is the failure to deal with the situation arising from fractional or divided interests in patent rights. The minority members point out that a patent may sometimes stand in the name of several owners. Is it sufficient to serve any one of them? Is it sufficient to pay royalties to the holder? If not how are the other owners to be brought in and made parties?

The loose manner in which the words "patented in violation" are used in the Oldfield Bill is severely criticized, and the results of the necessary construction, when a court is forced to complicate the law, are tellingly set forth. Theoretically every claim in a patent covers a distinct invention. In a patent containing fifty claims, twenty-five may cover inventions not actually embodied in the commercial product. Hence every claim embodies a potential invention, unlimited opportunities for engaging in compulsory license litigation are thus presented. This construction of the words "patented in violation" however fantastic and far-fetched it may seem, is obligatory. If it were not so, the minority might have felt that it would be possible to draw a patent with a hundred claims of which only one might be worked and ninety-nine with hold in flagrant evasion of the provisions for compulsory license.

According to Representative Oldfield and those who side with him an invention is suppressed if it is not adequately used. What is adequate use? In a previous issue we reviewed in these columns some of the difficulties encountered in interpreting the English statute containing a similar expression. The minority members point out still other difficulties. It is hard enough in an ordinary infringement suit to determine

whether or not the defendant has used the complainant's invention. The same issues would be presented in compulsory license proceedings. In other words, an application for a compulsory license involves a consideration of a patent's validity and scope, of questions of prior art, of the law by the simple expedient of negating the patent which it is desired to suppress to someone not engaged in producing any article in competition with the patented invention.

Was it oversight or simply a drastic discrimination against the patentee that induced those responsible for the Oldfield Bill to omit any provision which compels the applicant to accept a compulsory license and pay the royalties prescribed? An enemy of corporations, on reading the bill, would conclude that some industrialist stands behind Oldfield. How else could he explain the circumstances that the man who may lose the cost of litigation will be enabled to apply only indiscriminately for licenses and to accept only those which they may get on exceptionally good terms, with the privilege of abandoning the others after having put the minority members to heavy expense to heavy expense the value of their patents? The minority members fear that the entire assets of a small firm might easily be consumed in defending such a proceeding brought by a powerful corporation.

The purpose of the original Oldfield Bill so as to bring the patent monopoly within the Sherman Law is not approved by the minority. Framed as it was in executive session, without any public hearings to ascertain the views of inventors and manufacturers, the minority members feel that it cannot be seriously considered. That the Sherman Law is amply able to prevent the misuse of the patent monopoly, the minority prove by critically considering some of the decisions handed down in cases that involved an appeal to the conflict between the Sherman Law and the Patent Statute. The decisions indicate that there is no question of the right of excluding others from using or selling an invention in the manner prescribed by the patent law, the Sherman Act applies to patentees as well as to all monopolies. Moreover, the very recent decision in the *Eastman Kodak* case established that owners of patents are not exempt from the sweeping provisions of the Sherman antitrust act against monopolistic combinations, and that there is no such inherent natural distinction between owners of patents and owners of unpatented single products as to justify the application of the Sherman Law to the one class and not to the other. In a word, the proposed Oldfield reclassification of our patent statutes is a brilliantly unnecessary piece of legislation, which has needlessly worried manufacturers and alarmed every business man who deals in patented articles.

## Sir William White

WHILE most of us wander in life's by ways, exerting but a vanishing small influence on the progress of human affairs, into the lives of others is crowded such a vast number of events and activities, that the task accomplished seems to the beholder almost superhuman. In a space of sixteen years, from 1895 to 1910, William White, who has just passed from among us, destined two hundred and fifty warships. This was but one period in a life abounding with activity. A biography of the father of the Modern Battleship appeared in our columns only a few months ago. The reader will remember that William White, born on February 22, 1845, began his apprenticeship in the Royal Dockyard at Devonport at the age of fourteen, and after eight years training in the practice and science of shipbuilding, entered, in 1867, the service of the constructive department of the British Admiralty. In 1870 he became secretary of the council of construction appointed on the retirement of Sir Edward Reed, chief constructor of the Royal Navy—a post later occupied by William White himself. During these years, in addition to his connection with the Admiralty, he also held the rank of naval architect at the Royal Naval College, Greenwich. Among his students was Admiral Beatty.

It was because Sir William White's services to the Navy. To this phase of Sir William White's career must be reckoned also the publication of the well known "Manual of Naval Architecture."

In 1892 William White accepted an offer from the firm of Armstrong, Mitchell & Co. and became director of their new warship building department at Newcastle-on-Tyne. He held this post for three years, during

which he supervised the construction of a new shipyard at Newcastle, and constructed warships for Japan, Italy, Austria, Spain, China, and the United States. The total value of the contracts secured within these three years was about eight million dollars. During this period the United States Navy purchased two cruiser designs prepared by William White, and from these the "Charleston" and "Belmont" were built.

In October, 1898, William White was appointed Director of Naval Construction and Assistant Controller of the Royal Navy. Here he continued till 1902, when falling illness compelled a rest from his arduous task—at the age of fifty-seven he retired from government service. Two years later he was able once more to resume active work as consulting naval architect for the "Grand Line" "Mauritania."

That a man of the character of Sir William White should have taken an active part in the affairs of engineering societies and institutions is a matter of course. Many were the honors bestowed upon him—the knighthood in 1898, and the fellowship in the Royal Society in 1898 alone should be mentioned here. But the most appropriate monument to a great man is a grateful appreciation of his work, and in this the memory of Sir William White shall not be found wanting.

## The Scientific American Supplement

THE SCIENTIFIC AMERICAN SUPPLEMENT was founded in 1876 for the primary purpose of describing and illustrating the more important exhibits displayed at the Philadelphia International Exposition of that year. After the Exposition had closed, it was found that the many readers who had derived so great a pleasure that it seemed unwise to discontinue it. Accordingly, its publication was continued, and it was made a real SUPPLEMENT to the SCIENTIFIC AMERICAN in every sense of the word. While the SCIENTIFIC AMERICAN has always been primarily a newspaper in which the important scientific discoveries, engineering improvements and inventions of the day were promptly and briefly discussed, the SUPPLEMENT was reserved for the publication of highly important technical papers and before learned scientific societies, and the transactions of scientific publications of articles otherwise inaccessible to Americans.

The amount and character of the material thus printed is remarkable. Practically every field of science, both pure and applied, is represented. The articles themselves are penned, for the most part by the most competent investigators in their respective fields. In deed, the best scientific thought of the day has always been concentrated in the pages of the SCIENTIFIC AMERICAN SUPPLEMENT in papers written by the most eminent chemists, engineers, physicists, biologists, geologists, and natural scientists. In that respect the publication stands probably unique among all periodicals. We would like to introduce and make thoroughly familiar to our readers some of the authors whose names appear at the head of the articles published in the SUPPLEMENT, but the list is so long that space does not permit to give more than a brief selection. We see there the names of George Westinghouse, Mr. Logan Walter Page, Prof. W. D. Bancroft, Dr. Beekman, Prof. Hermann Prof. Wilhelm Ostwald, Prof. Fleming, Sir Oliver Lodge, Mr. J. J. Thomson, and others. Sir William White, Sir Robert Hadfield, and many others noted for the important share which they have had in advancing the world's knowledge and power over nature.

Since the papers of such distinguished men have more than an ornamental value, a printed outline of SCIENTIFIC AMERICAN SUPPLEMENT articles is published from time to time, which is distributed gratuitously and which indexes some ten thousand subjects that have been discussed from all angles. A complete list of the contents of the SUPPLEMENT, extending back to the year of its inception, thirty-seven years ago, is kept in stock, and copies can be supplied at any time at the published price. These lists, together with the outlines, form an expensive reference library within the reach of all at a nominal cost. So far as we are aware no other scientific periodical has attempted and executed such a feat as this.

The SCIENTIFIC AMERICAN SUPPLEMENT is supported by its subscribers, who pay no paid advertising, in which respect it again stands unique among scientific periodicals.

An "Elliott Turner" in Kansas Abuses—Application has been made to the municipality of Kansas Abuses for a 30-year extension to erect on public property the "Tower of Babel" in the city of Kansas. The plan is to build a 1,007 feet high, topped by a 108-foot chime bearing. Height of 1,000,000 cubic-pounds, making the total height 1,178 feet (200 ft. 8 in.) It is to be equipped with a wireless station, a meteorological observatory, and an automatic electrical clock.

## Engineering

**A Fatal Steamboat Explosion.**—The falling of a bolt among the spurs on a machine for grinding mud in a steam battery at Philadelphia many years ago caused a shower of sparks which ignited the finely divided dust and caused an explosion which injured six employees and killed one. Explosions of this character are common in coal mines and they have occasionally occurred in flour mills and other industrial establishments where inflammable dust is generated.

**Curious Drydock Disaster.**—During a gale a drydock at Spotswood, Glasgow, was suddenly flooded by the rush of water past the caisson gate, the workmen in the dock being drowned. The ship was blown from the dock blocks and she was filled with water, more of her plates being off at the time of the accident. An enormously high tide caused the caisson to lift from its seat. A similar accident happened in one of the drydocks at the Brooklyn Navy Yard many years ago, when the caisson gate, not having been sufficiently ballasted, lifted during a high tide, the water rushing in and launching two torpedo boats that were in the dock.

**The Ingots to Blame.**—At last the metallurgists, steel makers and rail users of the world are becoming thoroughly awake to the fact that the cause of the failures which result in broken rails is the ingot. Hunt, Falbott, Hadfield and many other eminent authorities have recently shown that we cannot be sure of the quality of rails unless we are assured of the quality of the ingots. The latest paper to this effect is by Henry Bloxson, an expert on our rail manufacturers are beginning to realize that they must concentrate their attention increasingly upon the furnace practice, and especially upon the ingot, if they are to turn out a reliable product.

**In Touch by Wireless.**—At Newport, R. I., we are informed by the Hydrographic Office in New York that recently the steamship "Barbaros" was in daily touch with the Hydrographic Office in this city by wireless throughout the whole of her voyage to the eastward across the Atlantic. Communication was maintained up to a distance of 800 miles by radio with the shore station of the Atlantic coast, when the "Barbaros" came in touch with Crookhaven, Ireland, and the messages were transmitted back by cable. The office has arranged to keep a record of the positions of ships, transmitted by radio, and the location of ice and derelicts is brought sent direct to the Hydrographic Office in Europe for transmission to ships starting on the westward passage.

**Vast Increase of British Navy.**—According to recent estimates the programme for the next five years will require a record of the positions of ships, transmitted by radio, and the location of ice and derelicts is brought sent direct to the Hydrographic Office in Europe for transmission to ships starting on the westward passage.

**Bids for Building the "Pennsylvania."**—Of the three best bids for the construction of our latest battleship the "Pennsylvania," the largest ship authorized under the construction—made by the Newport News, the New York Shipbuilding and the Fore River companies, that of the Newport News yard of \$7,255,000 was the lowest, and the contract has gone to that firm. The total cost of the ship when complete with guns, armor and equipment will be \$14,175,000. The "Pennsylvania" was described in a recent issue, in which her dimensions were given as 800 feet between perpendiculars, 625 feet over all, beam 97 feet, and draught 20 feet. The maximum hull-draught displacement is 32,000 tons. She will be the largest, best protected and most powerful ship afloat on the day of her launch.

**Steel Trains on the New Haven Road.**—The two five-hour express daily between New York and Boston over the New York New Haven and Hartford R.R., are now made up of new all-steel trains. These cars embody heavy cast steel U-shaped ends, forming the vestibules, connected by two heavy steel girders which make it well-nigh impossible for the cars to buckle or telescopic. Each train consists of four parlor cars, a combination parlor baggage car, a diner, and an observation smoker at the rear. The drawing-room has been dispensed with in the parlor cars. The ivory-white ceilings reflect the upward-thrown rays from ten 100-watt incandescent lamps, each of which is in a separate bronze brass reflector. Each car has two rows of incandescent headlights connected in multiple, which provide enough current to run the lights from two cars being made at stations, and even for ten hours independently of the electric dynamo driven by the car. The car is made of the best steel. The overhead system of insulation does away with all smoke. This system provides for the entrance of fresh air at the doors of each car and the discharge of used air through ventilators in the deck upper of the roof.

## Electricity

**Dr Arceon Honored by the Czar.**—The insignia and medal of the Order of St. Anne have been presented to Dr. Edward G. Arceon by the Czar of Russia. Dr. Arceon was the first to address the Russian Academy of Technological Institute in order to explain the nature and use of defoliated graphite. The order of St. Anne is one of the highest honors that can be conferred in the Russian Empire and carries with it nobility to the recipient. Dr. Arceon is a native of the Russian Empire.

**Transformers in the Lamp Sockets.**—The new German method of using a miniature transformer in each lamp socket has the advantage of allowing the use of a low-voltage metal filament lamp, for instance a 14-volt lamp, and such filaments are much stouter than the usual kind. It is also claimed that the low-voltage lamp is more economical in its use of current, and besides, the lamp is from 50 to 70 per cent cheaper than the others. Low-current lamps of three candle-power up can now be made with thick filaments, when using 14 volts. The usual 14-volt lamp has two filaments, one on each side, so that one can break and the other holds good. Each lamp has a small transformer fitted into the socket, and the key turns off the primary out of the transformer, so that there is no leakage current.

**Making Nickel Tubes Electrolytically.**—Nickel tubes and rods made by the new electrolytic process, which it allows of obtaining a thick deposit of nickel in a special plating bath. An acid solution of nickel sulphate is used, preferably as a hot bath. Nickel anodes are employed, and the voltage between electrodes should not exceed 1.5 volts. The density of current is 2 to 3 amperes per square decimeter of surface, and even more, as it is preferable to use a high-current density in this process. A very acid bath at 10 or 15 degrees B. is recommended. The metal thus obtained is very soft and can be plated in a thick layer. Nickel is deposited in this way on an aluminum form, then the form is separated by dissolving in caustic potash or by melting. A tube is best for this form. Thus the nickel is left in the shape of a tube, and the metal is said to be very tough and malleable.

**Electricity from Peat.**—In a paper read before the German Engineers' Association, M. Baurer brings out some ideas in the way of utilizing the great natural power which North Germany has in the shape of extensive peat fields, so that this can be used for a good part of the steam power needed for central stations. To keep pace with existing needs in this region the peat will have to be converted a number of electric plants giving a total of 10,000,000 horse-power, counting 8,000,000 in the use of railroads alone. As this part of the country has but little hydroelectric power, it is not possible to put a plan recommended by the author. In this way the great masses of logs would be dried up so as to have a large amount of land for agriculture and the like. In fact he calculates that North Germany contains enough peat to supply all the current needed in this region for as much as 220 years to come.

**Electroculture by High-tension Discharge System.**—A recent issue of a German electrical paper reports some successful experiments at Petrova (near Prague) in stimulating the growth of vegetables by high-tension discharges from a network of steel wires stretched across the field at a height of twelve feet above the ground. High-frequency electrical energy was transformed up to 100,000 volts and then rectified for delivery to the network. The total power consumption for the night was only 100 watts. The plants were two amperes 120 volts. By turning on the current for a few hours each day—except during wet weather, and during very hot weather when the discharge treatment is useless or even injurious—the quality as well as the yield of the crops was much improved. It was concluded that an electric plant designed to take a large output of electrical energy would pay for itself during the first year of operation.

**Flame Detector of Heriot's Wave.**—It is found by the German scientist Leithauer that a flame will act as a detector for wireless waves. At the sending end an oscillating current giving 0.54 megacycles per second was 3 feet long and at the receiving end placed about 60 feet off there is mounted an antenna which connects to one electrode placed within the flame of a Bunsen burner. The second electrode being connected to ground. The first electrode consists of a platinum capsule containing carbonate of potash, and the flame keeps it at a red heat so as to melt the salt. The other electrode is a 0.04-inch copper wire placed horizontally at about 0.1 or 0.15 inch from the first. Wires lead from each to a telephone, or in other words, a galvanometer. As the waves are sent out, there is heard a sound in the telephone. The current set up in the telephone seems to be caused by the flame acting as a current rectifier. Potash salts appear to give the best result, and lead electrodes must be kept at a red heat, however a difference of temperature is needed between them, and it should be noted that the direction of the current given off by the flame combination which appears to work as a battery, depends on which of the metal plates has the higher temperature.

## Science

**The Death of Louis Francis L. Harris.**—The last survivor of the Hayes expedition which went forth in 1855 to search for the remains of the ill-fated expedition of 1851, year of his age nearly 60 years. He was Louis Francis L. Harris. Although it stayed in the Arctic about two years and suffered great hardship, the expedition did not find Franklin. After the return of the expedition, Louis Harris enlisted in the Union Navy and fought through out the war.

**The Death of Dr. P. H. Hiss, Jr.**—Dr. Philip Hanson Hiss, Jr., professor of bacteriology in the College of Physicians and Surgeons of Columbia University, died recently in New York city, after a long illness. Although only forty-five years of age, Dr. Hiss had made a reputation for himself chiefly for his method of differentiating typhoid and colon bacilli, his method of isolating typhoid bacilli, his studies of the bacteriology of typhoid fever, his determinations of the relation of serum globulin and diphtheria antitoxin, and his researches on the causation of pneumonia and streptococcus and penicillin staining methods. His recognition of dysentery, typhoid and allied bacilli, his researches on the bacilli of the dysentery group, and his study of the urative influence of extracts of leucocytes upon infections also deserve mention.

**Water Hardness and Health.**—Hardness of water, that is the amount of lime or other salts which it contains, appears to have a direct influence upon the health as the researches of Dr. H. R. Boomer of Berlin bring out. Diphtheria, scarlet fever, and other diseases of school children, and examining several hundred to find that the percentage of persons having entirely sound teeth varies from 1.3 up to 20.2 per cent according to the degree of hardness of the water in various localities. Hard water contains lime, iron, and other salts, and magnesia appears to harden the enamel. The number of young men adapted for military service also increase in regions having hard water. As to action on the blood, lime and magnesia are left by the alkaline properties to strengthen the growth of children. According to this he states that soft water should be used for washing and cooking and hard water for drinking purposes.

**The Turkey Buzzard and the Hummingbird in the House of Representatives.**—On P. M. 8th March Mr. Akon of New York introduced a bill for the protection of the House of Representatives which resolution was referred to the Committee on Agriculture and ordered to be printed.

Resolved That the Secretary of Agriculture be and he is hereby authorized and directed to expend not exceeding \$100,000 for the purpose of purchasing and distributing to the States and ninety nine, throughout the United States, such birds as he may deem to be of the greatest value to the Bureau of Animal Industry, or to the welfare of fish and forest management. In order that a unit may be made in the value of the birds, he is authorized to purchase such birds as he may deem to be of the greatest value to the Bureau of Animal Industry, or to the welfare of fish and forest management. In order that a unit may be made in the value of the birds, he is authorized to purchase such birds as he may deem to be of the greatest value to the Bureau of Animal Industry, or to the welfare of fish and forest management.

These responsible for the printing of this absurd resolution ought to take a course in the correct appreciation of jokes.

**Detroit Observatory of the University of Michigan** has just issued the first instalment of its "Publications including an historical sketch of the institution by its present director, Professor L. A. Spiller. It is, in several respects, among the most interesting observations in America. It was built in 1854 with money raised by citizens of Detroit, whence its misleading name. (It is situated at Ann Arbor.) It was equipped at the outset with a 14-inch refractor, but in 1870 it was replaced by a 24-inch one—which was, when built, the largest refractor in the world and the first large telescope constructed entirely in the United States. The observatory is almost unrivaled among American institutions in the number of distinguished astronomers who have been connected with it, as directors, members of the staff, or students. A picturesque chapter in the history of the observatory relates to the discovery of 22 minor planets, between the years 1853 and 1877, by Prof. Watson. At this time, as then, but been lost, no observations of it having been obtained since those made at the time of its discovery in 1873 which were not sufficient for a satisfactory determination of its orbit. The planets discovered by Watson and others, the observatory has been connected with the National Academy of Sciences, and has been used in preparing and publishing tables for these bodies and the first instalment appeared in 1910. Since 1911 the director of Detroit Observatory has also been director of the Observatory of the University of Michigan. During his time between the two institutions, Watson's endowed planets, and Hume's shuffling between astronomical institutions, the history of Detroit Observatory has certainly been tinged with disaster.

## The Curtiss Military Biplane

### Description of the New Curtiss Tractor Aeroplane for Army Use

By Stanley Yule Beach

**T**HE new Curtiss biplane illustrated herewith has been produced in fulfillment of the specifications for army aeroplanes issued by the Government early this year. These requirements have been published in the SUPPLEMENT No. 1040 and a *summary* of them was given in our last issue. The chief requirements are that the machine must carry a load of some 600 pounds during a 4-hour flight; that it must rise at the rate of 200 feet a minute and that it must have a maximum speed not exceeding 65 miles an hour.

To fulfill these requirements Curtiss has produced a rather large biplane having a spread of 37 feet 4 inches for the upper plane and a total overall width of 38 feet 4 inches as against a length of 24 feet. The chord of each plane is 61 inches and their spacing apart .003. The weight of the machine complete is 1,050 pounds.

As will be noticed from the photo graphs this new machine is radically different from the former Curtiss military biplane. The use of a covered fuselage is in partial fulfillment of the army's requirements, and this, together with the placing of the power plant and propeller in front follows European practice. The

complete covering of the fuselage to reduce head resistance and the arranging of the radiator and motor in front, with a bonnet similar to that used on automobiles, distinctly more in regard to the "air" machine. The wings are much up as in one piece instead of in sections as heretofore and they are so set that their front and rear edges form a straight line, creating a certain amount of resistance from front to rear. This form tends to give the machine a certain degree of inherent force and stiffness. The unit construction of each section is such that in fitting the tail, rudder etc. make it possible to take apart the machine or put it together again in less than half an hour. One of our illustrations shows the four wings placed in position and the machine is to be turned over the road

The three-wheeled chassis has a maximum width of 66 inches reduced to 42 inches at the fenders while the track is 56 inches. The body is wide enough for two men to be seated in it comfortably and there is a panel removable from the lower plane on each side of the body to allow the occupants to look directly downward if they so desire.

Each cylinder has a separate control wheel so that either man or both together can drive the machine. A 40-hp engine drives a gasoline tank mounted on seats, but for running the airplane a small 2-gallon tank on the dashboards is hooked in to maintain the engine's drive from the engine. A gasoline pipe in the face of this tank makes it possible to see at all times the amount of gasoline in the tank, and whether or not the fuel is being working. Should the supply from the main tank cease by throwing a small lever and giving a few strokes of a hand at the controls, the engine will run from the main tank by means of air pressure developed therein. Another convenience is the carrying off of the oil and smoke from the engine below the seat. The engine is The up-curved dash in front of the airplane directs the blast of air from the engine into the rear fuselage. This is the largest machine thus built by Carlisle. It can be knocked down and packed in small boxes in short order. To estimate any of the four wings completely so that they can be packed in boxes is only necessary to remove four bolts.

The new method of wiring and bracing used in the fuselage does not require any holes to be placed in the main longitudinals, which are made of white spruce and which taper from the front to the rear. The body is so light that it supports itself a light skid being placed under the tail for protection only in making a bird landing. The head resistance of this machine has been reduced so that the machine is as fast as any of

the lighter bodyless types now used by the army. It is therefore a distinct advance as far as American military aeroplanes are concerned.

## A Canadian Arctic Expedition

**VILHJALMI R. STEFANSSON**, well known for his explorations along the Arctic shores of British America and for his discovery of Hound Eskimoes, has

just purchased for this purpose, and to spend about three and a half years in the Arctic. Dr. R. M. Anderson is to be second in command, and the scientific staff will probably consist chiefly of Canadians. The region to be explored is the largest stretch of completely unknown sea or land in the northern hemisphere. Certain peculiarities of the tides seem to indicate that it contains extensive land areas. On the eastern border

of this region is the supposed location of Crocker Land, which was sighted by Henry on his journey to the pole, and is to be sought by Macmillan's forthcoming "Crocker Land Expedition." It should also be noted that Amundsen's projected drift across the North Polar Basin will probably carry him into this unknown area.

McFadden hopes to land at Prince Patrick Island next September and establish his main base at Land's End. The ship is to leave him here, return to civilization and thereafter to make yearly visits to the base. Of course any such programme is liable to be more or less modified by ice conditions. From Land's End the party expects to make skidding journeys in various directions over as much as possible of the million square miles that are now a blank on the map.

The expedition will be equipped with a powerful wireless telegraph outfit, and it is hoped that the base station will thus be kept in constant communication with the world. This ought not to be difficult since the Canadian government is now establishing a chain of wireless stations in the far north of British America, including one at Herschel Island, at the mouth of the Mackenzie River. It is also proposed to carry a wireless outfit on the sledge in order to keep the explorers in touch with their base. A moving picture machine is to be included in the equipment of the expedition.

for some time been planning an expedition to seek for new lands in the vast unexplored region lying to the north of the Beaufort Sea and the Perry Archipelago. He recently secured the financial backing of the American Museum of Natural History, the National Geographic Society, and the Harvard Travelers' Club; but shortly afterward was invited by the Canadian government to undertake the journey under its auspices and at its expense. He has accordingly been released by the three American societies and the expedition will sail under the British flag. Stefansson is a Canadian by birth, but was educated in the United States.

The expedition is expected to sail from Esquimaux, B. C., the latter part of May on the whaler "Kariak."

fed in the case. The Court goes on to say that the art of producing metal castings by means of a mold formed of a wax pattern is very old, was practised by the ancient Greeks and Romans, extensively used in the middle ages for producing statuary, and is known as the "tre perdé" or "lost wax" process.

A Chair of Sericulture has been created in the scientific department of the University of Lyons, France, as a part of the general instruction in applied sociology. Funds for the payment of a professor and an assistant have been raised by the local chamber of commerce, as one means toward maintaining the supremacy of Lyons in the silk industries of Europe.

## The Growth of a Great Navy

### How Germany Has Advanced to the Second Position

By Percival A. Hisslam

THERE has been a vast number of changes in the last few years in everything that affects naval power, but none is more remarkable than the rise of Germany from a position of absolute insignificance into that of the world's second sea power. The work has been accomplished in the face of extraordinary natural difficulties, for not only are the Germans people essentially agrarian, but their harbors on the open seacoast have had literally to be dug out of the mud, and she must always remain under the heaviest of Nature's handicap, for the island of Great Britain stretches like a great breakwater between Germany and the ocean.

Considering the part Germany plays to-day in the naval politics of the world—she has 11 completed dreadnoughts to England's 18, and to America's 8—it is difficult to realize that her naval expenditure did not reach \$25,000,000 until 1907, and that the fifty million dollar mark was not passed until ten years ago. From 1906 onward her naval expenditure has totaled well under a half of Great Britain's and yet in that period she has launched 18 armored ships as compared with that nation's 22, and with the 10 of the United States. The German fleet is largely manned on the conscript system and it is this, of course, which accounts very largely for the champions of her naval service.

To realize the truly marvelous growth of German naval strength it is not necessary to go back more than ten years. In 1902 her naval expenditure was \$50,225,000 and it has increased so rapidly that no less than \$113,047,200 is being spent this year. The number of officers and men totaled for the fleet in 1902 was 11,000. For the current year the figure is 42,070, and under the recently adopted amendment to the navy law of 1900 the personnel is to be increased to 101,500 by 1920. For two years after England completed the "Dreadnought" (in 1905) Germany was putting into service battleships of 10,000 tons, more than 50 per cent short of her displacement, but the armored

Length, 610½ feet. Beam, 90 feet. Displacement, 22,640 tons. Speed on trial, 30 knots. Armament, ten 11-inch twelve 5.9-inch twelve 4.4-inch four torpedo tubes. Main armor belt, 7½-inch. Coal, 8,100 tons. Oil, 200 tons.

Germany's latest battle-cruiser, "Goeben."

Length, 604½ feet. Beam, 95½ feet. Displacement, 24,110 tons. Trial speed, 28 to 29 knots. Armament, ten 12.3-inch, fourteen 5.9-inch fourteen 3.4-inch, six torpedo tubes. Main armor belt, 15½-inch. Coal, 8,500 tons. Oil, 300 tons.

The latest German dreadnought, "Kaiser."

ships launched for Germany from 1900 onward have actually exceeded in average displacement the vessels launched for the British navy. It has been truly said that a battle fleet is not made in a shipbuilding yard or alongside a dockyard wall, but on the high seas, and the German fleet has measured its bulk, its progress will show no less striking. In 1902 the "High Seas Fleet" consisted of 8 battleships, 2 armored cruisers, and 22 destroyers. Today it consists of 16 battleships, 4 armored cruisers, 12 small cruisers and 40 destroyers and by 1914 it is to be increased (under the provisions of the recent amendment to the navy law) to 25 battleships, 8 battle and armored cruisers, 18 small cruisers, 60 destroyers, and 54 submarines, all of which will be permanently in full completion.

Naturally, the fleet of Germany at sea is felt much more keenly in England than in any other country, if only because a distance of no more than 500 miles separates the principal German naval base of Wilhelmshaven from the English North Sea coast. Whether Germany hopes some day to become the world's principal naval power (and the Kaiser has said, "The trident of Neptune must be in our fist," and "Our future lies on the water") is a political matter that cannot be discussed here, but she has at no remote such progress in her armaments, and in 1904 Great Britain has been compelled, in order to preserve her superiority in her home waters, to withdraw 10 battleships from foreign stations (14 from the Mediterranean and 5 from the Pacific) and to concentrate practically the whole of her resources around her fleet. The extension of which Germany has actually improved her position is shown very strikingly in the following comparison between her fleet and the British in 1901 and at the present time in the principal classes of ships, according to all cases vessels launched over ten years.

	—1904—		—1913—	
	Britain	Germany	Britain	Germany
Battle cruisers	30	10	27	14
Battle cruisers	10	4	5	1
Protected cruisers	17	17	17	22
Destroyers	120	77	107	88

When the original dreadnought was laid down in 1905 it was claimed in England that the new type of ship would not only strengthen her position very greatly against other important naval powers, but that smaller nations with pretensions to a fleet would be quite unable to do business. This was not the case, however, at the actual result. Some of the minor nations that had not laid down a battleship for a quarter of a century or thereabout are now engaged in more or less similar dreadnought programmes, these including Brazil, Argentina, Chile, Turkey and Spain. And in Germany was concerned, it enabled her to start afresh with a clean slate, and although it is true that the appearance of the "dreadnought" paralyzed the shipyards of Europe for nearly two years, they were merely asserting themselves properly for the first time before they started on it. The result is that while England completed seven dreadnoughts before Germany completed one, the latter nation has completed 11 since 1904 to England's 11.

Again, until the "dreadnought" appeared Germany had been content with comparatively feeble ships. The battleships she launched between 1892 and 1901 carried nothing larger than the 9-4-inch gun and the ships of the "Deutschland" class, the last of Germany's pre-dreadnoughts, displaced 10,000 tons, compared with the 16,000 tons of the British "Lord Nelson" and the 16,000 of the "New Hampshire." The first American dreadnoughts were no larger than the New Hampshire, and the step between the "Lord Nelson" and the "dreadnought" was only 1,400 tons, but Germany came from the 15,000 tons of the "Deutschland" to the 15,000 of the "Nassau," an advance of 42 per cent. This phase of German progress is shown in the following table which gives the average tonnage of battleships launched in successive years.

	American	British	German
1905	14,400	16,300	11,040
1906	16,000	16,000	11,040
1907	18,000	18,000	11,040
1908	17,388	19,200	16,000
1909	20,012	19,575	22,440
1910	21,266	20,388	22,440
1911	22,000	20,940	24,110

Thus, while American designs have gained and kept a considerable lead over the nations ships, those of Germany have compared with British vessels, risen from an inferiority of 1,400 tons in 1900 to a superiority of 1,170 tons in 1911. On the other hand, however, German designers do not seem to have any knack of converting tonnage into fighting power. Their 25,000-ton ships of the "Kaiser" class mount only ten 12-2-inch guns in their main battery, representing a broadside (over a limited angle) of 9,810 pounds. The corresponding British ships have ten 12-5-inch on the center

line, with a broadside of 12,500 pounds, while the American "Wyoming" have a broadside of 10,440 pounds, and the "New York," 14,000 pounds. The German vessels have a large and torpedo battery—fourteen 5.9-inch and fourteen 3.4-inch, as compared with twenty-one 5.9-inch in the American, and sixteen 4-inch in the British ships, but while a battleship is, of course, a compromise, the battle guns of the German ships of the "Kaiser" class give 407 pounds of broadside for every 1,000 tons displacement as compared with 200 pounds in the British "King George" class and 516 pounds in the "New York."

The German navy now comprises 8 battleships and 3 cruisers of the dreadnought type in service and 9 battleships and 8 cruisers in various stages of construction. The four earliest battleships, "Nassau," "Westfalen," "Rheinland," and "Posen," were launched in 1908. They displaced 16,000 tons, and with reciprocating engines of 20,000 horse-power have stemmed from 201 to 214 knots, while their armament consists of twelve 12-inch and four 5.9-inch guns, and sixteen 3.4-inch guns. They were followed by the "Holgoland," "Thüringen," "Ostfriesland," and "Oldenburg," launched in 1909-10, and displacing 22,440 tons. Their armament consists of twelve 12-2-inch, fourteen 5.9-inch, and four 3.4-inch guns, and their speed (with 25,000-horse-power) range from 20.8 to 21.6 knots. These eight ships have their big guns arranged very inefficiently, there being only two turrets on the center line and two on either beam, so that only eight guns bear on the broadside. This is because the broadside guns of the "Nassau" (16,000 tons) is only 6,000 pounds, while that of the "Mölgand" (16,000 tons) is 6,000 pounds. The main armament of the first four German ships is 9.9 inches, and of the latter four, 10.4 inches of shells, according to each case in 6 inches forward and 4 inches astern.

The battleships under construction fall into two groups. The first comprises the "Kaiser," "Friedrich der Grosse" (both under trial), "Kaiserin," "König Albert," "Prinzregent Luitpold," having a displacement of 24,110 tons, a designed speed of 20 knots (the "Kaiser" has made over 23 in a sprint on trial), and an armament of ten 12-2-inch, fourteen 5.9-inch, and four 3.4-inch guns. The main weapons are in five turrets, of which three are on the middle line, one forward and one astern, and the inner one is being superposed to bear astern. The other two turrets are on *echelon* emplacements, so that there is nominally a full broadside. The angle covered by ten guns is, however, necessarily small (about 30 degrees), and while the armor belt measured to 12 inches, the broadside that very good value has been obtained for the increase of 1,000 tons over the preceding group. The "Kaisers" are the first German battleships driven by turbines, the horse-power being 28,000.

Of the latter battleships very little is known save that the authorities are having a good deal of trouble over their armament. The vessels concerned are known as the "Ernst von Seydlitz," "Kaiserin," "Friedrich Wilhelm," "Ernst Braunschweig," and "K." It was at first intended to give them either thirteen or fifteen 12-2-inch guns, but this would have involved triple turrets, and these have, in Germany, proved a failure. As an alternative, ten 14-inch were decided on, but here again, while Krupp have had a 14-inch on hand for a long time, they have been unable to produce a mounting that satisfies the requirements of the admiralty of the fleet. There is a possibility of twelve 12-2-inch in six center line turrets being adopted as a solution.

America has already made the acquaintance of German battleships, the "Ernst von Seydlitz" having visited New York in August in 1910, while the "Kaiser" was at New York recently. The former is practically a copy of the British "Indefatigable," having eight 11-inch in four turrets, two on the center line and two *echelon*, well apart longitudinally, amidships. Her torpedo defense battery consists of four 20-inch and sixteen 8-4-inch guns, while her belt covered speed is 28 knots with turbines of 44,000 designed horse-power. Her displacement is 10,100 tons. The "Moltke," her successor in order of building, displaces 22,640 tons, and carries an additional pair of 18-inch guns in a superposed turret aft. She has made 23.7 knots with turbines developing 80,000 horse-power. The recently completed "Goeben" is similar to the "Moltke," but has been credited with a maximum speed of 32 knots. Expectations, however, that the German navy is rapidly improving already exaggerate the speed of their ships.

#### Comparative Dreadnought Strength.

	Complete	Battleships	Total
	18	18	36
Britain	11	12	23
Germany	11	12	23
United States	8	8	16
Japan	2	5	7
Italy	2	1	3
Spain	1	1	2
France	1	1	2
Austria	1	1	2

\* Including those given for 1915.

It is understood that life last battleship to be launched, the "Seefriede," will carry ten 12-2-inch on a displacement of 27,000 tons, and of the remaining vessels, the "K" and the "Ernst Kaiserin Augusta," of the 1911 and 1912 programmes, nothing definite is known.

No other nation has yet completed a ship of the all-big-gun type.

#### The Ambrose Channel as Measured by the Panama Canal

WHEN we place two objects side by side for comparison, we may try to estimate the equality of the superiority of the one or the inferiority of the other, or again, we may be merely using one as a standard by which to measure the other. It is with this last impartial and dispassionate purpose in view that we have placed some figures relating to the Ambrose Channel beside similar figures relating to the Panama Canal.

When we learned that the broad ship channel cut through the shoals of New York's lower bay was 90 per cent completed, that nearly sixty-five million cubic yards had been removed from it, and that some five million yards more still be dredged, we knew that we had a large quantity to deal with, but how large, it was difficult to grasp without using a bigger unit of measure. After searching about for a suitable yardstick, we were quite as astonished as our readers probably were, to find that the Ambrose Channel is no means too large a measure for the purpose. The estimated total excavation of the Panama Canal will amount to about two hundred and ten million cubic yards, or almost exactly three times that of the Ambrose Channel.

To show what this amount of material means in terms of units that are still more familiar to us, we have pictured in the front page illustration two pyramids similar in form, one made of the material excavated from the Ambrose Channel, the other from material excavated from the Panama Canal. Taking the smaller pyramid as 750 feet high, or just large enough to reach to the top of the Woolworth building, the tallest office building in the world, the base of pyramid would be 2,750 feet square, that is, each side would have a length of 525 feet.

A similar heap of dirt and rock from the Panama Canal would make a pyramid only 1,000 feet high, overtopping the Eiffel tower by something like 100 feet, while the base would measure 4,000 feet square. How could a pile of dirt and rock be so much larger than the other? The answer is, of course, that our very dear home occupied with so little comment? Can it be that things look larger and more important in proportion to their distance? No. This distortion of mental perspective is apparent, not real. There is no doubt that the work here would be aided by a stream of water, it would receive great attention and even exaggerated importance. If the same excavation were made in New York City, it would cut a swath nearly as wide as Central Park, and stretching from Canal Street to 125th Street, and about 15 feet deep, magnitude at our very door would be a very different matter. It is not nearly so important or difficult an engineering undertaking as that of the Panama Canal. Excavation with dredges is far more economical than excavation with steam shovels. The Ambrose Channel was started eleven years ago, and is now practically completed, and yet only four dredges at a time have been used on it, and these dredges were manned by 288 men altogether. At present only two dredges are used in completing the work. On the other hand, the excavation at the isthmus of Panama has required the services of a veritable army of men. Thirty-five thousand men are now employed. As a matter of fact, what is left to be done in the way of cleaning up the Panama Canal will be accomplished by means of dredges after the manner in which it is now being done, but that of excavation is so much more economical and speedy.

Our front page illustration shows what an enormous load a single dredge will carry. The dredge is provided with two bins, each holding 1,400 cubic yards. To transport 4,800 cubic yards on land would require a train a mile in length, or, as shown in the illustration, four trains, each a quarter of a mile in length. These powerful suction dredges will take on a full load in less than three hours, then go out to deep water, drop the load, and return within an hour or so. The question upon whether their station is near the shore or the inner end of the channel. The load that is taken on is not, as one might suppose, a very fine mud and sand or mud and water. Of course, the mud is moist, but it is practically a solid load from the water. The material in the bins above it is not, but it is not as one may walk upon the load without sinking in. As has been explained to our readers before, the material is sucked from the bottom through two pipes, one on each side of the hull, 80 inches in diameter, and provided with a drag the lower end of which is made of mud and water is pumped up by powerful centrifugal pumps and delivered into the bins which, after filling, permit the water to overflow while the next

neath. Then the bins gradually fill up with the sediment, mud settles slowly, and much of it is carried off with the overflow, so that when and as being excavated it takes much longer to fill the bins.

At present practically all the work is completed except for a few stone piles, and for some excavation still to be done along the southern edge of the channel. The stone piles, by the way, are rather interesting. A number of years ago, when harbor regulations were not strictly enforced, it was quite the common thing to dump loads of stone in the lower bay. Many of these have been encountered in excavating the Ambrose Channel. The stone drags the mud down, and has openings in them, measuring 7 inches by 5 inches, and will suck up anything of that size, be it stone or iron. However, most of the stones in the stone pile are too large to pass through the drag. They could be removed by using bucket dredges, but a simpler method was evolved, i. e., to bury the stones where they lay. To do this holes from ten to twenty feet deep are dredged around two sides of the stone piles, and then the survey boat with its water jets loosens the pile of stones, letting them fall into the grave dug for them.

The dredges are capable of excavating to a depth of sixty feet. The depth of the Ambrose Channel, however, is 40 feet below mean low water. The width of the channel, as we have stated before, is 1,000 feet, and the banks at each side have a 10 per cent slope.

As to the importance of the Ambrose Channel, the tonnage of shipping that passes through it seems very large indeed. It has been estimated that for the first few years, the total tonnage of shipping passing through the Panama Canal will not greatly exceed ten million per annum. In 1912 it was probably somewhere between fifteen and twenty million. Just how much shipping passes up the Ambrose Channel, it is difficult to determine. A record is kept of foreign vessels entering and clearing the port of New York, but no record is kept of coastwise shipping. The tonnage of shipping engaged in foreign trade amounts annually to about twenty-seven million, and practically all of it comes up through the Ambrose Channel. The coastwise tonnage is considerably more than this, but how much more no one can state definitely. For this reason we have left it out of consideration.

In our comparison, and have shown a single ship of ten million tonnage capacity representing the shipping that will pass through the Panama Canal and a twenty-seven million ship representing the foreign shipping passing up through the Ambrose Channel. It is only that the waterway of the Ambrose Channel should have no visible banks. Passengers who go through the Panama Canal will ever prize the boatmen who carried that great work to completion, as they see the enormous cut of (Cuba, the huge Gatun dam, and the massive concrete locks. The waterway of the Ambrose Channel will ever prize the boatmen who carried that great work to completion, as they see the enormous cut of (Cuba, the huge Gatun dam, and the massive concrete locks. The waterway of the Ambrose Channel will ever prize the boatmen who carried that great work to completion, as they see the enormous cut of (Cuba, the huge Gatun dam, and the massive concrete locks.

### The Current Supplement

IN an article on Modern Microscopic Optics C. Metz, in this week's issue of the SUPPLEMENT discusses the limitations of the microscope, and the refinements in its optical system introduced by modern practice. The English correspondent of the SCIENTIFIC AMERICAN describes a remarkable railway for tourists' service in the Yosemite mountains—An important article dealing with the use of the Panama Canal as one of the excellent work done by the British authorities in this direction—Dr. R. C. Bennett tells us "Why Smoke is an Industrial Nuisance"—How to Make an "Electroscope" is the title of an article by C. E. Benham. Mr. John Jay D. L. Hamilton, Jr. writes as the author of a number of articles on the principal types of aeroplanes, describes for us the Morse-Hendler monoplane, the holder of the world's highest record—Prof. H. C. Jones of Johns Hopkins University writes on "Electricity and Chemical Action," a subject which especially qualified to write on. The SUPPLEMENT gives the question, whether interstellar space contains a medium which absorbs light.

### Parcel Post Hampers

THE interest in parcel post appliances will be heighted by the report that Postmaster-General Hitchcock has made a contract for 6,000 hampers to be used in the carrying of parcel post packages. The hampers are intended for experimental purposes and are made to nest. They are constructed of canvas and some metal, as well as of wood and fiber, making light construction. It is reported that hampers which can be designed for use in the nest must be fragile so that most of the type have been made at yet. Many frames of collapsible containers must be devised which would not be open to the objection referred to.

## Correspondence

[The editors are not responsible for statements made in the correspondence columns. Anonymous communications cannot be considered, but the names of correspondents will be withheld when so desired.]

### Spring Wheels

To the Editor of the SCIENTIFIC AMERICAN

Referring to the letter in your issue of February 1st entitled "Fallacy of the Spring Wheel," Mr. Plimber states that the spring wheel will never become a practical success, his reason being that the springs in the wheel must undergo so many more flexures than the elliptical springs of the car.

This is of course true of a great number of spring wheels, but the obvious answer is that if the flexures of the springs in the wheel are in excess of the elliptical springs, the springs must be so placed in the wheel that no flexure occur in excess of the flexures of the elliptical springs.

New York City

HARRY E. SIKK

### The Bow Rudder

To the Editor of the SCIENTIFIC AMERICAN

In your issue of January 25th, answering the letter of A. H. Kiesel, you make the following statement: "The bow rudder is in use on special types of vessels, particularly on ferryboats, the practice being common in American harbors."

All of the ferryboats on the Atlantic coast of which I have record, are steered entirely by the after rudder, the forward rudder being locked, thereby losing the function of a rudder, in fact the forward rudder can be converted into the after pilot.

I believe that under certain common conditions of current, the bow rudder could be used with steves, but I have yet to see one in operation.

Providence, N. J.

### Position of Projectiles in Flight

To the Editor of the SCIENTIFIC AMERICAN

"The Flight of Projectiles." Re article of H. W. B. in your issue of December 21st, 1912, page 581.

His second paragraph is as follows: "If a projectile rotated on an axis absolutely identical with its trajectory, the criterion would be that the projectile would not depart from the condition that causes the drift. The moment the projectile leaves the gun, the force of gravity begins to pull it away from the path of the axis of its rotation, and this slight deviation is enough to make the axis of rotation 'unstable'."

It might be well for the writer to point out the analogy referred to, especially since the drift of a baseball and of a bullet are in opposite directions as pointed out by Twining, and especially since Twining states that the criterion of a ball's drift is entirely different, and, in other words, that there is no analogy whatever.

Red Deer, Alberta.

### The Nature of the Patent Monopoly

To the Editor of the SCIENTIFIC AMERICAN

Regarding the proposed legislation for eradication of the monopoly element from our patent laws.

Would it not be well to consider with exceeding care the matter of this alleged monopoly element, and to demonstrate conclusively its existence, before moving to eradicate it?

While in a general way it might be admitted by me that the inventor is a producer, there appears to be no intelligent understanding of the fundamentals of this important subject, and the general opinion appears to be that in granting a patent to an inventor, society confers upon him a monopoly, or a benevolent gift, or a privilege of society, for which gratuitous gift, the inventor is obligated to society, as, for instance, he would be should he receive free a valuable franchise, by means of which franchise he might live in idle luxury at the expense of society. In short, the inventor is considered, whatever attitude toward him be professed, a privileged seeder, a deliver into the "pork barrel," a monopolist, and a black-mailing grafter.

It is denied that the inventor is or can be a producer, he is considered merely a forerunner, an appropriator of nature laws in justice free to all, for that no man can produce by mental exertion alone.

This inventor, who may be without hands or feet, says to society, after sitting for years in exhaustive thought, "I have conceived a new mechanical design, and I expect to materialize it in the form of a machine, will you labor of a thousand men, carrying society by the labor saved. What will you give me to disallow it, and how will you guarantee payment?"

Society at present replies: "In the first place, you are a liar, you have produced nothing, for you have neither hands nor feet to produce with. Secondly, you are a thief, because you have appropriated and hold sacred possession of our natural rights, but, as we know no

means by which we may forcibly dispossess you and recover these our rights, and as we greatly desire possession of them, we will agree to your blackmailing claim, by granting you a patent right upon the device."

But, if the inventor cannot produce without limbs, how can he steal without them, and what thing economically has he stolen from society?

If all the claims of society gathered into the possession of a Paton or a Bully, how can monopoly result from such concentration the wheat or cotton being a labor product and therefore property? How can more than temporary inconvenience result provided the land from which the wheat or cotton was produced is still accessible to society for the production of a further supply of the desired product?

Thought applied to language produces word combinations or literary designs for the expression of opinions or ideas. Unless titles to language is conferred upon an individual, so that he alone may produce literary designs how can monopoly result from any individual possession of copyrights on these literary designs, which rights concern a labor product?

Thought, applied to the laws of mechanics, produces mechanical designs, which expressed materially are valuable to society. Unless titles to the laws of mechanics be conferred upon an individual, so that he alone may produce mechanical designs, how can monopoly result from individual possession of patent rights on these mechanical designs, which rights concern a labor product?

A chemist burns the midnight oil in useful research for fifty years while his fellows enslave. Feeling his energy waken, he writes the results (in a few hours perhaps) of his years of study, copyright, and rests from labor upon the oil of his head. There are millions of people sufficiently hardy to die (that this writer is a producer, and to assert the equal right of the public to publish and will this man a book without payment to him).

The inventor, whose is undoubtedly the most exhaustively consuming and poorly paid of labor, he being well-nigh universally a low physically and financially produces his mechanical design by years of conscientious, grinding, mental toil and financial expenditures, while the public idly await his product, whereupon these latter, too lazy to produce their own designs, or too grudgingly dishonest to acquire them by purchase, proceed to slanderously declare him a grafter and to actually demand copyright on the results of his own production.

I must deny that the inventor is a grafter, and that a patent monopoly is or is possible of existence with the basic laws of mechanics as maintained freely accessible to society for the production of mechanical designs.

If Congress, therefore, in well-intentioned ignorance, or at the behest of selfish interests legislates away from the inventor his property rights into the hands of non-producers Congress will be guilty not alone of confiscation, but of the very worst sort, because confined to a particular class.

It will discourage unto death the inventive art the most useful of arts, and when all too late, society will realize that in this snatching the product of the inventor a toll great has at last burnt the back.

Newark, N. J.

J. H. RUMBY

### "Snow-rollers"

To the Editor of the SCIENTIFIC AMERICAN

The little article "Wind-rolled Snowballs" in your issue of March 1st is an interesting contribution to a subject with which meteorologists are tolerably familiar, but apparently the editor of the SCIENTIFIC AMERICAN has no knowledge of the character described as known technically as "snow-rollers." (See the Supplement to the "Century Dictionary.") It is likely that some of your readers will be glad to be referred to further literature on the subject.

The most extensive account of snow-rollers in the English language is that given in the *Quarterly Journal of the Royal Meteorological Society* of 31 1908, pages 87 to 98. This is mainly a compilation of accounts of the phenomenon previously published in scientific books and journals, and is illustrated. None of these accounts appeared in the *Monthly Weather Review* (published by the U. S. Weather Bureau).

Probably the most important contribution to the subject of snow-rollers is the article, *Schneewalzen* by Rudolf Meyer in *Korrespondenzblatt des Naturforscherversus zu Basel* vol. 52, 1897. This gives a list and analysis of all known to the writer between the years 1826 and 1906, and is accompanied by a bibliography which lists 25 previous papers on the subject, in a verbal language.

Snow-rollers were observed in Morris County, N. J., in January 1890 by Rev. D. A. Clark, when it is stated that "the whole landscape was covered with snowballs, differing in size from a lady's muff to the diameter of 2 1/2 or 3 feet, hollow at each end to almost the very center, and 4 1/2 as true as so many logs shaped in a lathe."

Washington, D. C.

U. S. Weather Bureau.

## "Uncle Sam's" Appraisers of Merchandise

### How Imported Goods Are Examined by Experts to Determine the Duties They Should Pay

PERSONAL liberty in the United States is so complete that we scarcely realize there is a power central government to watch over our destinies and make us comport ourselves with proper regard for the rights of citizens in our neighborly States. Frequently an American's first real contact with Federal power comes on the return from a trip abroad, when he is advised that he must pay duty on goods that he has brought with him. He may have looked with contempt on the poor foreigner who must submit to the petty rigidity of an officious government, and he may be returning with a smug better than thou attitude only to receive a rude shock to his complacency as the customs officials board his vessel and make him swear out a statement of his dutiable personal effects. Then no matter if he does consider it an invasion of his rights as a freeborn American citizen, he must submit to having his trunk opened, and searched more or less perfunctorily, to make sure that he has not perjured him self. He may even be called aside for a hasty searching questions about a certain piece of jewelry. Now, how did Uncle Sam know that he had that trinket? For the first time he is aware of a spy system, not unlike that of Russia, which reaches out beyond our shores to foreign lands and keeps track of the purchases of the American tourists. Despite the humiliation of being treated as a smuggler he cannot help but feel a great respect for the constabulary of a government whose existence he barely realized up to that moment.

Although examination of travelers' baggage is the most troublesome work that the Customs House has to deal with it is a paltry business compared with the collection of duties on general merchandise. The total amount of duties collected for the year ending June 30th, 1914, on articles entered for consumption was \$34,903,000. Just how much of this came from the traveler is not reported, but obviously it was a small percentage.

It is equally obvious that the cost of collecting this duty must have been very great as compared with that on general merchandise. And yet, despite the far greater attention to personal baggage, smuggling still continues among tourists, especially those of the gentler sex who display remarkable ingenuity in concealing their dutiable goods. One customs official hopefully admitted that women are born smugglers, and we cannot hope ever to suppress them.

As for general merchandise the opportunities for smuggling are so remote the co-operation between the Government and the importers themselves is so complete and the penalty for smuggling is so severe as compared with the reward it offers, that practically no goods enter the country without paying duty. Take diamonds for instance, which one would suppose could very readily be introduced into the country because their value per ounce is so enormous. Not only does the Government keep track of purchasers of diamonds abroad but the dealers do as well and they are constantly on the lookout for "washed stones," realizing that it is to their own interest to report any stones introduced without paying the required tariff. Furthermore, to make it unprofitable to smuggle the stones into the country, the tariff on them was reduced several years ago from 25 per cent to 10 per cent.

Some idea of the enormous amount of work involved in keeping track of the goods that enter this country may be obtained by a visit to the Appraisers' Store on the lower west side of New York. The building is ten stories high and takes up an entire block, while across the street is an annex of no mean size. In these buildings at least 10 per cent of everything that comes

Testing the color and strength of tea.

All Cuban leaf tobacco must be minutely examined.

Stamping imported cigars after they have been thoroughly inspected.

into New York from foreign ports must be examined. During the year 1911 close to 700,000 cases of merchandise, representing merchandise worth a billion dollars, passed through the Appraisers' Store, and the goods varied all the way from a toothpick to an automobile, and from a rare tapestry to a dead Chinaman's queue. A sample of literally everything under the sun finds its way at one time or another into the Store, and no matter what its character may be, whether a fifty-cent diamond or a penny doll, it must be gravely considered and its value accurately and scientifically

determined, so that the proper custom duty may be levied thereon. To handle this enormous quantity of material requires the attention of 4500 men, of whom 120 are examiners. The duties of the examiner are exceedingly difficult. Each man has a certain classification assigned to him, and he must be prepared to determine the wholesale value of any of the various articles that might turn up under that classification. He must be able to tell of just what material or materials the article was made, how much the materials were worth in the market from which they came, and just what was the value of the labor which was expended upon it. Not only that, but he must know the market value of the materials and labor at the time of shipment. This must be determined on his own knowledge and not on the word of the shipper. He cannot depend on anyone else, but must stand on his own statement, which he must be ready to back up with incontestable evidence in case the importer carries an appeal to a higher court. He must be able to detect all the tricks with which unscrupulous manufacturers delude the ignorant public. For instance, in the tax law department the examiner must be able to tell whether a piece of goods contains cotton, linen or silk, and in what proportion. Having determined this, he must know the quality of the material used in making it up. If it is of silk, he must determine whether the silk is artificial or natural. If natural, what kind of silk, and where it came from. If he is in doubt about the matter, he refers a sample to the laboratory, where the fabric is subjected to a chemical analysis in order to determine accurately what its composition may be. Naturally an examiner acquires before long such an experience as to qualify him as an expert, an experience that it is impossible to obtain anywhere else.

Recently, curiosities, works of art, and antiques, over a hundred years old, have been admitted free of duty. When the tariff was removed on such objects, this country was immediately flooded with all sorts of curios from every known part of the world, and the poor examiner had to determine whether these objects were at least a hundred years old. When we consider that the articles came from the most remote regions, we can readily understand how difficult was the work. Possibly the most interesting work in this connection is that of determining the age of old furniture. Professionals as well as amateur collectors are duped by clever imitation, and frequently it is not until the examiner in the Appraisers' Store determines the period to which the article belongs that the purchaser discovers that he has been swindled. Usually the examiner can tell at a glance to what period an article belongs. He is not fooled by artificial weathering or by bird-shot fired into the wood in order to give it a worn, antique appearance, but he is puzzled sometimes when he finds that around a small portion that really is antique, parts of a more recent date have been applied, or modern wood and varnish have been used to restore a wrecked piece of old furniture.

The examiner who has to appraise the work of artists has an exceedingly difficult task. In many cases it is not at all easy to distinguish between genuine and genuine old masters. The work these examiners is of undeniable value to the country in preventing the importation of counterfeits.

Similar protection against fraud is found in the case of tea. No duty is levied on tea, but all tea must be examined for purity before being admitted into the country. In the tea room of the New York Appraisers' Store a hundred thousand samples of tea must be tested per year, which represents an import of about

Assaying an alloy in the metallurgical laboratory

Testing sugar solutions with the polariscope to determine percentage of cane sugar

Decolorizing and filtering sugar solutions for polariscope test

forty-five million pounds. One of the photographs shows the manner of testing. Each cup contains a different sample of tea identified by a number marked on the bottom of the cup, and one of the cups contains a standard sample. Which one it is the examiner does not know, for the identification of this sample also is marked on the bottom of the cup. The examiner then proceeds to arrange the cups according to the color and taste of the tea. After the grading is done the samples are thrown away and the cups turned upside down to show the identifying numbers. All the samples on one side of the standard are passed as good tea, while those on the other side are rejected. To make sure that no error has been made the test is repeated with a second set of samples. In order to detect any pigment used in the tea the leaves are mashed on a piece of white paper, and then the paper is examined with a microscope for faint spots of colored matter. The tests are very rigid and thorough and the United States may pride itself on having nothing but pure tea to drink.

Perhaps the most tedious work at the Stores is the testing of sugar. The tariff on sugar depends upon the proportion of cane sugar the samples contain. This is determined accurately by means of a polariscope which analyzes the light that passes through samples of the sugar syrup. When a beam of light is passed through a Nicol's prism the transmitted light vibrates only in one plane. When this polarized light passes through the syrup its plane of vibration is distorted to a certain extent depending upon the quality or nature of the syrup and on the length of syrup it must pass through. By comparing this distortion with a certain standard it is possible to tell just what proportion of cane sugar is contained in the syrup. To prepare the samples for the polariscope fixed quantities of sugar must be carefully weighed, dissolved in a measured quantity of water, filtered and decolorized. The work is very wearisome and trying, with no variation to relieve the monotony. In the case of sugar only samples are brought to the Stores, and as a check upon the examiner, two samples out of each barrel are given him. Each sample bears its own number but the examiners have no means of determining which two came out of the same barrel. Nevertheless, his work must be so accurate that when like samples are paired again the readings will be practically identical.

The laboratories of the Stores are also kept busy with quantitative analyses of various chemical products, particularly in the search for alcohols in medicines, etc. There is also a section devoted to metallurgical analyses.

Obviously it would be impossible to examine every article imported into the country, and so it is the practice to bring at least one per cent of a shipment to the

Analyzing drugs and medicines for acids, alkalies, oils, etc.

Smuggler's vest, thirty-six pockets for watches and jewelry

How the smuggler conceals dutiable goods in books.

Examining cases of dry goods.

Stores. If the shipment consists of but one or two cases of goods at least one case must be examined. The cases that go to the Stores are picked out at random by the examiner. He compares the contents of the case with the invoice and then investigates one of the articles under the invoice minutely in order to determine its quality. If this tallies with the specifications the case is passed. In certain classes of goods, however, the entire shipment must be minutely scrutinized and appraised. In the case of leaf tobacco for Indians, every package must be opened in order to determine whether the leaves are good enough to be used for wrappers which must carry a duty of one dollar and eighty-five cents per pound, or whether they are fit only for pipes, which pay thirty-five cents duty. Certain classes of tobacco which are obviously inferior do not come in for such careful examination but in the case of Cuban tobacco, a hundred per cent must be brought to the Stores. In the appraising of cigars, a very careful count and estimate of weight and value must be obtained, for not only must the tariff be collected but the boxes or bundles must pay a tobacco tax.

We cannot go into all the details of the work at the Appraisers' Stores but we have mentioned enough to show that it is of a most exacting nature. We must also pay a tribute to the high character of the men employed in this work. It is hard to understand how the Government can afford to hire so many experts as a matter of fact the salaries are not at all proportionate to the experience and quality of work. Frequently an examiner steps out of the Stores into a position with some manufacturer at a salary many times greater than that he has been receiving from the Government. However, as a rule the men are content to stay in the Appraisers' Stores because they become devoted to the work and find it full of never-ending interest.

#### Artificial Marble

THE following are directions for making artificial marble. 1. Burnt gypsum is saturated with a solution of lime in alum water burnt ash or ground flint or rather pulverized adding 1/12 by weight of the gypsum of alum and cast in the mold. These harden very slowly, but attain the hardness and transparency of marble. Different pigments may be added to obtain different colored marbles. 2. Pieces of burnt gypsum the size of a flat are put for 1 hour in a 12 per cent solution of alum in water of a temperature of 55 to 104 deg. Fahr. burnt ash or pulverized adding 1/10 powdered alum and loosely worked into molds with water containing 1/16 mol ammonium for each part of gypsum. Castings made of this combination possess great hardness and brilliancy and it may, therefore be used for the statues—Vase, etc. *Erfindungen und Erfindungen.*

# Power from Kerosene

## A System Whereby Oil, Kerosene, and Distillates are Used in the Ordinary Type of Gas Engine

By L. W. Ellis and W. R. Dray

THE intelligent public has been slow to adopt the oil engine. It has been educated by use to internal combustion engines which make an explosive gas out of cold gasoline. Through its familiarity with the oil in the tank, it has come to demand an oil engine that will be established as a gas engine practice. Probably the greatest single factor in such disposition is John A. Seccor has earned in his early formulation of the doctrine that the oil engine need not and must not vary in principle from the gas engine. Second only to that however ranks the discovery of the means for using oil without sacrificing a single desirable feature of the best gas engine. The work which is just beginning to have world-wide recognition offers an answer to the general demand. The following article abstracted from a longer article appearing in the February 15 issue of the SCIENTIFIC AMERICAN SUPPLEMENT explains the principle of the invention.

The Seccor patents 1) a unit apply to engines which differ from the familiar gas engine type, such as the Diesel and the oil engine type, not to the type using the hit and miss governor. They are applicable to the the hit and miss engine only.

Stated briefly the Seccor system covers (1) an automatic variation in the quantity of fuel mixture, in accordance with the slightest variation in speed and load (2) a degree of compression dependent upon the quantity of the mixture inhaled (3) a correct proportioning of the mixture under all conditions involving relatively wetter mixtures for the lighter compression and increasingly stronger mixtures for the lower compression (4) a temperature of combustion exactly adapted to the quality of fuel used and the compression (5) automatic control of the internal temperature through the adjustment of water as a part of the fuel mixture (6) thorough and uniform mixture of the fuel water and air charge by mechanical means and without the application of additional heat (7) automatic variation in the time of firing in response to variations in the speed and power (8) means for changing the limits of a definite speed within which all factors are simultaneously controlled (9) and means for starting on a limited supply of volatile fuel all of which factors are vital to the control of internal heat, the transformation of heat into power and power production. These features are now embodied in commercially successful engines which have been adapted to a great variety of stationary and traction work.

One great factor in the success of the system is that through the mechanism of the Higgins carburetor, the proportion of fuel, air and water are simultaneously varied in relation to each other as the compression changes. By this means the conditions within the cylinder whether the engine be run at heavy and or light are constant so far as they affect the completeness of combustion. Complete combustion eliminates the deposit of carbon which has been regarded as an insurmountable objection to the use of heavy fuels and the unified automatic control results in the securing of sparkless ignition.

Crank shaft cam shaft governor mounted control valves and siphon act as a positive control unit in engines equipped with the Seccor system hence no mechanical factor deserves to be set apart from the others in importance. However the Higgins carburetor which makes possible the application of the Seccor system is of sufficient value to warrant special attention. Fig. 1 shows the top view of a two-

cylinder tractor motor equipped with the Seccor Higgins system. The cam shaft is gear driven and in turn drives both governor and magneto timing lever gears the fly ball governor, through a first class lever and a link coupling operates a sliding brass plate which is clearly shown in Fig. 2. The carburetor sits above the cylinders with the short inlet manifold presenting the opportunity for the mixture to stratify before it is

Fig. 1—Top view of two cylinder motor equipped with the Seccor Higgins system

Fig. 2—Higgins carburetor, showing air intake and manifold

completely exposed. It contains constant level chambers for kerosene and water an overflow being provided for each. It has also for starting purposes a chamber for gasoline which is filled by hand pump. This chamber which holds about a pint is connected by a siphon with the mixing chamber. Turning the engine over creates suction enough to draw upon the contents of this chamber, but a vent is provided so that

if a start is not made immediately the siphon will not continue to act and drain the chamber.

Fig. 3 shows the position of the valve plate at light load. Two air inlets are then open, providing a large ratio of admission to outlet area and thus greatly reducing the relative vacuum in the mixing chamber. As the load increases, the governor thwarts the sliding valve forward increasing the area of the outlet to the cylinders increasing the air inlet in the middle, and decreasing or entirely closing the air opening at the right. Thus the ratio of admission to outlet area decreases the relative vacuum becomes greater, and more fuel in quantity though not in proportion, is picked up by the incoming air and carried to the cylinder.

A sectional view from the side (Fig. 4) shows the arrangement of the kerosene and water needle valves the overflow etc. It will be noted that the water level is lower than the kerosene level. The suction, therefore, is not great enough, until the engine reaches about half load, to lift the water to the point (H) where it can flow down the tube surrounding the needle valve. From half to full load the ratio of water to fuel increases rapidly until the amounts of fuel and water used are practically equal.

The carburetor is so designed that the fuel needle valve A should be adjusted at the full load position when the plate is farthest to the right. This order of procedure is important since at this position the adjustable plate has no effect upon the area of the air inlet openings. The adjustment of the air should be made at the full load position and after once made need never be changed unless the engine enters a very different altitude. This adjustable plate allows each carburetor to be adjusted to the engine it is to serve hence the slight variations in manufacturing are fully taken care of. The sliding valve is the only moving part in the carburetor and that is positively controlled there are no springs, floats or check valves. Wear cannot affect the size of the air openings which control the relative vacuum in the mixing chamber, therefore the accuracy of the carburetor will never be interfered with by any ordinary cause.

Ignition is necessarily electric and in large engines where the speed variation is great means have been devised for automatically advancing the spark as the speed increases. In ordinary engines however only such manual adjustments are needed as provided as will take care of the starting and normal speeds.

One of the most noted gas engine builders in the country has adapted this system to a line of station air kerosene and distillate engines which will operate in size from 50 to 170 horse power. His factory tests show an efficiency of over 15 brake horsepower per gallon of kerosene on 80 horse power single cylinder engines at all loads from about one third to about below the maximum. The manufacturer's literature gives a guarantee of within 2 per cent on speed regulation. One other large licensee making stationary engines in size from 1 to 15 horse power is achieving considerable success through a series of electric lighting and power outfits suitable for the country house or small business. The generators are direct connected yet give steadier power than the average public service in the smaller towns. The 18 Government is using a number of engines fitted with this system to drive air compressors for foghorns in life-saving stations on the Great Lakes.

A six cylinder marine engine using the Seccor Higgins

Fig. 3—Position of sliding valve at light load.

Fig. 4—Longitudinal section of carburetor.

system develops a brake horse-power hour from 0.6 pint of kerosene. A large number of Recor engines are being used by the Japanese government for operating electric lighting and wireless telegraph stations, and these engines have been adapted to a great variety of uses in this country, where safety and close speed regulation are essential. Naturally, insurance rates are much lower where a non-volatile fuel is used.

The widest use of this system however, has been made in connection with farm tractors. One factory built more than 50 tractors a week as an average for the year 1912. These engines are meeting with universal success, operating on the kerosene and distillates of the United States, on gasoline in South America, and on the lighter grades of crude oil found in the United States and Southern Russia. A two-cylinder tractor, 10-horse-hp by 12-horse-hp stroke, running at 875 revolutions per minute, recently developed in an official contest at Winnipeg, Manitoba, 51 brake horse-power in an economy test with a consumption of 0.71 pound of fuel per horse-power hour, and 76.5 horse-power in a maximum test on 0.85 pound of fuel. This is a grade of fuel which sells at \$16 to 7 cents in barrel lots in country towns throughout the Central States, and weighs nearly 7 pounds to the United States gallon.

In the Winnipeg Motor Contest of 1911 a single-cylinder engine of the same type averaged 0.85 of a pint of fuel per brake horse-power hour on kerosene and 0.93 of a pint per brake horse-power hour on gas oil. The kerosene contained 16 to 20 per cent more heat units than gasoline, hence the engine running on kerosene, while a trifle more economical in regard to volume of fuel used, was a trifle less efficient thermally. In the last three such competitions, the fuel cost of the tractors operated under these patents has been constantly lowered and has remained at or near the lowest point recorded, while the speed regulation has been secured perfect in nearly every instance. The recent winning of a gold medal and sweepstakes over more than twenty other tractors, including four steam and fourteen gasoline, indicates that the desirable oil burning feature has been achieved without sacrificing any points of efficiency. These tractors are being used by ordinary farm hands in every condition of climate and altitude without further adjustment than is provided for in the simple carburetor.

# **Military Automobile Gun** By the Paris Correspondent of the Scientific American

Ever since the employment of aeroplanes and airships has become one of the recognized elements of modern war, attention has been called to the question of cannon for firing upon objects of this kind, and naturally a combination of an automobile with a suitable gun for use in firing at high elevation is sought for. In France where military aeroplane questions are more keenly taken up at present, designers have been working upon an automobile cannon of this sort, and we here present the most recent and successful type which comes from the De Dion automobile works, this construction having been carried out according to plans furnished by Capt. Houton and other army officers belonging to the engineering corps. The automobile is made as light as may be compatible with the load which it is designed to carry, as the car is required to run at a good speed, and to carry this out a good sized 4-cylinder motor is used. On the rear end of the chassis is mounted the cannon with all the proper devices for the firing at a high angle. A turntable base which can be rapidly rotated so as to secure a rapid aiming of the gun is here employed, and another device allows the gun to turn upon its transverse, the height being controlled by a toothed sector and gearing operated by a hand wheel. All the movements are rapidly carried out, as is required for directing the gun upon objects in the air. When running on the road and on, of use, the gun is let down so as to come into the horizontal position, and lies close to the base. During the firing, it can take all inclinations up to 70 degrees, and in this way it fires almost vertically, as our engraving shows. The new automobile gun is meeting with favor in the army, and it has already shown a very good performance in the military maneuvers.

## **Recent Improvements in the Storage Battery**

THERE are about fourteen hundred patents in the storage battery art, as granted by the United States Patent Office. A still larger number is found in the foreign patents. The casual observer might assume

Fig. 1—Morrison's zinc lead-dioxide cell, showing screens A of copper wire

Fig. 2—Structure of cell used in Baas's electrical battery

The automobile gun on the road and out-of-use, comes into horizontal position and lies close to the base.

The automobile gun during firing can take all inclinations up to 70 degrees.

from this that there was nothing left to be desired in the battery; or that there was no room for further large improvements. On the contrary, the perfect storage cell has yet to be discovered. However, the present day form of cell is steadily, although not spectacularly approaching perfection limited of course, by certain inherent qualities that cannot be overcome.

**The Lead Storage Cell.** In the lead storage cell alternate plates of sponge lead and lead dioxide are separated by insulators, series respectively as negative and positive pole electrodes in an electrolyte of sulphuric acid. Upon discharge the lead is oxidized and the dioxide reduced, the resulting products uniting with the acid to form lead sulphate. Upon recharge, the reverse reaction occurs. Due to these molecular changes the active materials expand and contract. Heretofore the main difficulty in making a battery that will stand up under the stress of use, the oxides being poor electrical conductors and being adherent to a metallic support is essential. The vast majority of patents deal with the structures of such supports. Either a lead oxide paste is applied upon a metallic grid or is held in a perforated container according to the Baum method, or the active material is electrolytically formed *in situ* upon a plate, finally comprising, this closely spaced rows of lead by the Planté process of alternately oxidizing and reducing the plate.

**Expansion.** Active material where exposed on the exterior of a plate tends to flake off or disintegrate, or the various expedients to obviate these difficulties, the use of a so-called expander is most common. That is the active material is impregnated with a finely divided inert insoluble substance, often an electrical conductor, or example, Rodman soaks the dried plate in barium nitrate solution and the dip it in sulphuric acid thus precipitating insoluble barium sulphate within the pores of the electrode. He also subjects a plate of barium lead alloy to anodic oxidation in sulphuric acid which thereby forming lead dioxide and setting free the barium in the bath, then transformed in a sulphate. Ford soaks his plate in a tannin solution containing, dissolved calcium sulphate in suspension. Morrison uses oxygen compounds of chromium, titanium, niobium or tungsten. For example he describes the ordinary lead dioxide as an anode in a sodium tungstate solution thereby forming a tungsten oxygen compound within the pores of the electrode. Morrison also describes the use of such agents as nitrocellulose, especially celluloid or rubber vulcanized in the plate.

**Initially Formed Active Material.** Salom works on the problem from another viewpoint. He first electrolytically forms or as it were charges the sponge lead or lead dioxide so that it is initially fully expanded and then applies it to the grid under hydraulic pressure. The sponge lead is heated in allowing, water to evaporate from the powdered lead crystals thus oxidizing it, especially throughout.

**Quick Discharge.** An essential for a quick discharge is that the pores in the active material be so large that the acid does not become impoverished at the working surface. This has been accomplished by mixing the lead oxide paste with various compounds which are or as it were charge the sponge lead or lead dioxide so that it is initially fully expanded and then applies it to the grid under hydraulic pressure. The sponge lead is heated in allowing, water to evaporate from the powdered lead crystals thus oxidizing it, especially throughout.

**Hammer in Denmark** makes a plate from a mixture of a metal and alloy, a lot of lead and antimony applies heat until the cathode alloy becomes fluid while the remainder is solid and then squeezes out the fluid particles leaving a sponge plate. It then subsequently precipitates metal of a higher melting point within the pores heats and melts out the original material.

Tate accomplishes the same end in a bifunctional electrode made up of lead-based strips, alternately positive and negative and suitably separated by porous carbonaceous plates, which carry a supply of acid. Each strip is about one-half inch wide and the active material is but one thirty-second inch deep thus expending substantially the whole mass to the electrolyte.

## Ice-boating

A FEW weeks ago we described the exhilarating sport of motor ice-boating and showed some of the more substantial types of motor-driven sleds. One might be tempted to think that the motor ice-boat would eventually render the wind-driven ice-boat obsolete. Such, however, is hardly likely to be the case when we consider the rare sport that can be obtained with the wind-propelled vehicle. The accompanying photograph shows an exciting moment in an ice-boat race. The ice-boat is lifting to an alarming angle and it seems as if it must surely topple over but it will right itself and continue on its course. Surely a sport affording such exciting moments is not liable to die, for ice-boating is purely sport, and there is no utilitarian reason for introducing motors as has been the case in sailboats. The only reason for the motor ice-boat is that it affords a different kind of sport. The two types of ice vehicles will surely be continued and developed side by side.

An ice boat "lifting" to an alarming angle

Apparatus for keeping a tuning fork in constant vibration.

Transporting a bridge girder in Southern India.

Protected by shields in a network of high-tension wires. Standing on the shields while fixing an arc lamp.

How the Indians in California store their acorns for winter use.

## The Micro-monophone

THE micro-monophone is a tuning fork kept in permanent vibration by means of a microphone contact. This is an improvement over the familiar tuning fork interrupters for the reason that its sound is much clearer while the current curve approaches much more closely to a sinusoidal form. Two views of the apparatus are shown herewith. The tuning fork is actuated upon a resonance box. The prongs of the fork are situated in the field of an electro-magnet on which is superposed the field of a permanent magnet. The coils of the electro-magnet are arranged in series with a microphone mounted at the closed end of the resonance box. The support for the microphone is such that it may be moved to bring the lower carbon electrode into contact with the resonance box. When current from a battery is passed through the microphone and the electro-magnet and the tuning fork is set vibrating by means of one or two slight knocks, vibrations will be transmitted through the resonance box to the microphone producing variations in the magnetic field of the electro-magnet which in turn acts upon the tuning fork and keeps it vibrating. Thus we have a complete cycle of operation, the tuning fork keeping the microphone in operation and the latter by means of the magnet keeping the tuning fork vibrating. The tuning fork will then operate as long as the battery current is complete or unbroken. By reducing the current intensity the purity of the sound is increased.

## Acorns and Their Uses

VERY little attention has been given in this country to the utilization of acorns. It is well known that they are used as food for cattle, horses, swine, turkeys, and those of several species of white mice also form the food of man. The acorns of white oaks are mostly large and the trees in general produce fruit very abundantly. The Indians in California always gathered the acorns of the California live oak (*Quercus agrifolia*) and *Yucca* of great secrecy often caused much misery. Even the early white settlers of California relied on the crop of acorns as a part of their food supply. The acorns were gathered in the autumn, when preserved them in putting them in wicker baskets which were usually stored in hollow oak trees or in caches as shown in the illustration. They were prepared for eating by grinding and boiling them with water into a thick paste which was baked into bread. The oven consisted of a hole in the ground about 18 inches deep. Red hot stones were placed in the bottom of it and a fire of dry sand or bark placed over them. Next a layer of dry leaves was spread over this and the dough or paste poured into the hole until it was two or three inches deep. A layer of leaves, more sand, red hot stones, and finally earth

was placed on top. At the end of 5 or 6 hours the stones had cooled and the bread, which was an irregular mass nearly black in color, was taken out.

In parts of the South acorns of the cow oak (*Quercus emoryi*) have been used when roasted as a coffee substitute, and there are a good many other uses to which they might be put. Alcohol can be extracted from them, as from all starchy substances. Starch is at present made principally from rice, corn, and potatoes, but if the starch from acorns is sufficient by refined it may be employed as an article of diet as well as for laundry purposes. Acorns contain much sugar and gum, and it is probable that these substances can be profitably separated and successfully used for domestic purposes. Even the residue could be sold very profitably for fattening hogs.

## Engineering in Southern India

AT first sight there appears to be nothing very remarkable in the accompanying photograph which shows the floating into position of a large girder. The girder is a hundred and fifty feet long and it is supported in the well known manner upon two floats to permit of transporting it down the river. The weight of the girder is 200 tons, certainly not remarkably heavy. But closer inspection of the photograph shows a small boat on the river with a lantern sail, and in the foreground a dugout canoe which gives us the hint at once, that the girder is being transported on some oriental stream. It seems rather incongruous, does this introduction of a bit of western engineering in the picturesque Oriental stream. The girder is being floated down the Netravati River at Mangalore, Southern India, over which waterway a bridge is being built. Although the transporting and placing on its pier of such a girder is a simple matter in our land it is no inconsiderable feat where ignorant natives workers must be relied upon.

## Rubber Shields for Linemen

OF the millions of people employed daily about exceedingly dangerous tasks, few are subjected to greater danger than the linemen employed in the thousand upon thousands of electric lighting and power companies. These men daily place themselves in the most hazardous positions among high tension wires. For the protection of this class of employees a rubber shield has been invented.

The shield has the form of a rubber trough. It is used in all possible positions where the body of the operator may be exposed and is also used as a means of protection in trimming arc lamps and repelling broken wires from the ground in the latter case. If the weather is dry the shield is simply stretched upon the ground for the workman to stand upon, but in case of wet weather when this insulation is not sufficient the shield is closed at the flaps.

The appliance is manufactured of pure gum rubber, three layers of the rubber being used in two layers of canvas, the latter alternating with the rubber sheets. The second layer of canvas used is laid crosswise to the first layer, and in this way adds greater strength to the shield. The thickness of the rubber varies from  $\frac{1}{8}$  inch in locations where it is liable to be subjected to pressure to  $\frac{3}{16}$  inch along the closing flaps. The contrivance is fastened to the wire by two hard rubber rings. These are slotted with an aperture sufficiently large for the wire to enter and then clamped by this means firmly to the wire from which the linemen must be protected.

Each shield is subjected to a test of 20,000 volts unimpregnated, but it is recommended that the protector be used only with voltages not exceeding 10,000.

It will also be noticed that this new life-saver fits over the insulators, and in fastening it to the wire the linemen grasp the rubber handles attached to the outside ends of the shield in such a manner that it is between his hands and the wire.

## A New Gear Engine

Two small spur gears cutting through a steam chamber at their intermesh point—this is practically all there is to an engine, which has recently been tested at the laboratory of Columbia University, at the power house of the New York Central Railroad, and at the Chicago and Northwestern power house where it developed thirty-five horse-power with better economy than the average multi-stage turbine or piston engine of equal power.

The construction of the engine is shown in the accompanying drawing, in which the two gears *A* are mounted in a suitable casing *B*. At their intermeshing point there is a centerpiece *C* containing two steam chambers, for this is a reversing engine. The dotted lines *D* and *D'* outline the chambers, and the communal case with the pipes *E* and *E'*, respectively. When steam is admitted through the pipe *E*, it fills the chamber *D* and can escape therefrom only by propelling the teeth of the gear wheels in the direction of the arrows. The escaping steam fills the casing *B*, and most of it escapes through the exhaust *F*. Some of the steam is carried by the teeth into the chamber *D'*, and escapes through the pipe *E'*, which is connected with the exhaust. When it is desired to reverse the engine, the pipe *E* is connected with the exhaust and steam is admitted to chamber *D'* through pipe *E'*. Such is the construction of the single stage type of engine. Very evidently the parts may be duplicated to produce a multi-stage gear engine.

The following is a report on the engine tested at Columbia University Mechanical Laboratory and the New York Central Power Station:

"The results show a very good water rate for this size of unit. The engine has the following salient points of design: Speed may be varied over a wide range. Weight per horse-power and floor space per horse-power are very low. No foundation is required for this size unit, the machine tested was operated without vibration under load up to 4000 revolutions per minute standing on a wooden bench. There are no gears, no dead centers and no reciprocating parts.

The external gears establish the running clearance of the working gears, so that there is no contact and no lubrication in the engine required. It has a high starting torque, as the full steam pressure can be utilized at the outlet. The engine is symmetrical with respect to steam and exhaust, so that it can be reversed without difficulty and operates equally well in either direction. The engine is entirely enclosed, and slugs of water have no effect except a temporary slowing down. As the engine can be equipped with two pulleys requiring in opposite directions,

belts can be operated if necessary on very short centers, as one pulley can act as an idler in securing additional wrap on the other pulley. It obtains its good water rate by eliminating most of the other losses which occur in small engines and turbines, such as cylinder condensation

have brought to light an entirely new method of expanding steam, heretofore unknown to authorities on thermodynamic principles. The expansive power is obtained in this new cycle while the steam is working at a continuous flow against a series of platons, having what is termed an in-

and leakage in a reciprocating engine, and windage and steam friction in turbines."

This engine easily delivered 50 horse-power on the brake and the above figures were obtained from that load. Various tests have been made in the past on the single-stage unit to determine the increased economy of the multi-stage gear engine. The results of these tests

finite meet between them, which consists of merely steam passages between successive and closely adjacent stages, the number of stages determining the amount of expansion obtainable. The following is quoted from a report by Prof. Farr based upon tests made by Prof. Elgood (both of Columbia University):

## Machines for Printing Railroad Tickets

In a large railroad system the cost of supplying tickets, and testing tickets to passengers is no small item. In the western generally followed in this country each station agent is required to keep on hand a stock of complete tickets for each principal station on the road, and think tickets for the less important ones in which the name of the destination is written or printed with a rubber stamp. This latter class of tickets is always a source of trouble, as that they are subject to forgery and the liability to error in accounting. Furthermore, cumbersome ticket cases are required to hold these tickets and in large stations such cases take up much valuable space.

In view of the foregoing facts it would appear that a comparatively simple and practicable machine by which it would be possible for the ticket agent to print each ticket as it is called for would receive careful consideration in the railroad companies. Many line companies have been invented for doing this work. Practically all of them have a fixed plate for printing the body of the ticket, such as the name of the road, the conditions under which the ticket is sold, etc., and movable or removable type plates for the place of destination and date. These also are so arranged that at the destination of each ticket printed is also printed on an auditing strip which is of great assistance to the agent in nullifying his accounts, and may be turned in with his reports.

In Fig. 1 is shown the first complete machine of this kind patented in this country in 1872. A roll of paper in ribbon form having printed thereon the main body of the tickets is placed in the machine, the end of this ribbon passes up over a feed roller in the upper cylindrical part *b* and thence out over the platen at the top. A curved arm *c* is pivoted at the back of the machine, and at its front is recessed for removably holding the type plates *d* for the destination and the date. At each complete revolution of the crank shaft the paper strip is fed forward the space of one ticket and in means of a carrier *e* an ink line *f* is passed over the type plates and the arm is brought down on the platen thus completing the ticket. The ticket thus printed is then cut off. The auditing strip *h* is drawn into the machine, the ink strip and is fed forward at a slower rate and the identifying matter is printed thereon at the same time the ticket is printed.

The next view (Fig. 2) shows one of the most recent forms of this type of machine. In the upper part of the engine is a horizontal shaft turned by a crank and carrying a mutilated bevel

# THE MULTIGRAPH SYSTEM *EFFICIENCY METHODS:*

## Advertising and Printing - Folding and Sealing

### That's the Family

THE Multigraph System embraces many means and methods of aiding business. It would probably help *your* business in one or more of the following ways:

Producing your own direct-mail advertising, including perfect typewritten form-letters and real printing;

Printing your own office and factory stationery and system-forms;

Save 25% to 75% of the price you are now paying your printer;

Saving time, space, waste;

Contributing a free advisory service in connection with advertising, selling and other business problems;

Preparing your advertising and correspondence for the mails.

It would seem that these benefits would help your business; but whether they would help enough to pay for the investment can be determined only by investigation. If you wish further information or desire one of our representatives to call, you have only to ask.

The Basic Multigraph. For form letter typewriting and general form printing. Adapted with all-in-one type set semi-automatic feeding.

Multigraph Letter Holder. Makes set-up printing letter fields, electrically driven. Also makes set-up. Universal folding. Marking for larger work.

Mail graph (complete Unit). For printing advertising, business and other electric drive stationery and mail printing with attachments.

Multigraph Printer. The printing and of the Multigraph system. The typewriting and mail where printing directly records typewriting.

Multigraph 4. Complete. The typewriting and of the Mail graph without the proofing and set. Set type with set-up printing.

Multigraph 4. Complete. The typewriting and of the Mail graph without the proofing and set. Set type with set-up printing.

### You Can't Buy a Multigraph Unless You Need It

You need have no fear that a show of interest will lead to importunity upon our part. We will not sell you a Multigraph until we are satisfied it will stay sold. We must be sure that you can use it to your own profit.

Your business must furnish the facts, but we will gladly send a representative to help you ascertain them.

Begin your investigation today. Get in touch with our nearest branch office; or write us direct, on your business stationery, for interesting information. Use the coupon.

#### What Uses Are You Most Interested In?

Check the box or boxes which interest you most. Write in the space provided your name, address, and telephone number. We will send you a representative to help you.

## The Industrial Need of Technically Trained Men—I.

Scientific Manufacturing and the Opportunities It Offers

By Waldemar Knappert, Managing Editor of the Scientific American

IT is the intention of the SCIENTIFIC AMERICAN to publish a series of monthly articles on the professional opportunities that await the technically trained engineer, physicist, chemist, bacteriologist and technologist in modern life. Last year, it will be remembered, a series of articles was published written for the most part by well known educators connected with our leading technical institutions. They showed how institutions of technology were endeavoring to meet the requirements of great manufacturing railway and municipal corporations. This year's series, written by the heads of great corporations—companies which are capitalized at millions of dollars, which employ thousands of men, and which are scientifically organized and managed—all show how great is the need of technically trained men and engineers. An introduction to the series is published the following review by our Managing Editor, the purpose of which is to give a glimpse, as it were, of the rich prizes that can be won by the trained technologist.—[EDITOR.]

The modern manufacturing corporation, which requires acres of floor space to carry out its processes, which uses countless hours' train loads of wheat, leather or iron ore into four shoes, or steel rails, needs more men than horses. So vast are its operations that it pays to save a few cents in the production of a ton of pig iron, to devise a steam shovel which will scoop up five tons more at a time with a slight increase in the consumption of energy than was possible before to annihilate the wastes of manufacture and to devise means of utilizing them. Still more important, it is forced to ignore the technologist. Competition is no longer confined to the selling market. There is a rivalry in improving manufacturing methods as well as in mechanical efficiency. Men are sent to business men on scientific and engineering investigations that would have been regarded as purely menial twenty years ago but the ultimate commercial value of which is incalculable, equivalent to the broad-minded merchant of today. Even the manufacturer who employs only a dozen men must engage in this intellectual rivalry. He cannot always afford to employ the most talented men, but he must at least obtain the advice of a consulting chemist or engineer if he is not to be utterly crushed.

Despite the utilitarian and commercial character of much of the scientific investigation undertaken by the great modern manufacturing corporation has a fascination all its own. Indeed, the results thereof often affect not simply one particular industry, but a whole science. In the city of Cleveland for example one of our great electrical companies maintains a number of laboratories, the sole purpose of which is to improve our methods of utilizing electricity. It gives us a light which is more efficient than anything now produced. The studies there conducted involve chemical and physical research of a high order, physiological and psychological studies of the effect of various illuminants on the human eye, engineering researches that will necessarily bring us nearer to the "cold light," of which the lighting engineers have lately written so much. In a word, the subject of light is studied with a thoroughness never before attempted and with a total disregard of money. Who can doubt that research thus conducted will not shortly enrich the world with illuminants better and cheaper than anything we have now, but that the whole science of optics will assume a new importance?

Because of the huge capital which commands the modern manufacturing company can experiment on a stupendous scale to realize an idea current in theory. The development of the fourth steam turbine, for example, involved the expenditure of millions. That vast sum was not spent in empirical experimenting, but in practically testing the thermo-dynamic views of engineers whose one task in life was the perfection of the steam turbine. Work such as this is comparable with the finest research conducted in any university. What is more, it is richly paid for, for your great manufacturing corporation, unlike your street university, is not averse to rewarding the trained man to whom the development of its processes is due.

It has been supposed that the all-devouring trust crushes its weaker rival by the sheer weight of its money. The truth is that trained minds easily triumph over mere money. In twenty-six public hearings recently held in Washington by the House Committee on Patents, to consider the views of inventors and manufacturers on the advisability of introducing compulsory licenses into our patent system, it was abundantly demonstrated that the trained technologist could make a match for the trained capitalist. The counsel for the greatest sewing machine manufacturing company in this country testified that were it not for the experimental laboratory conducted by three or four smaller sewing machine manufacturers, the company that he represented would undoubtedly monopolize the market. In other words, a handful of highly paid and thoroughly trained technical men were able by their ingenuity to cope with the dominating company.

Before the same Congressional committee Mr. Spencer D. Miller, a well known inventor, drew a vivid picture of the manner in which a modern manufacturing company utilizes trained engineers. Mr. Miller has made a life study of conveying machinery. To him we owe the system of conveying material which has been adopted by the United States Navy. He revealed the manner in which his company had deliberately studied market conditions and devised machinery to meet special needs. The result, for example, had long been hailed out of Louisiana swamps at an enormous cost. Mr. Miller was engaged to devise the best mechanical system possible for taking out the logs. He did so with such success that not only were the logs now eventually sold far below their old price but that swamp land which had once brought only \$1 an acre, commanded \$15 per acre. Experts like Mr. Miller have trained technologists who are needed here and more.

The American telephone system a marvel of efficiency, is the creation of a dozen engineers whose work is confined entirely to the improvement of a telephone communication. They are engaged at princely salaries to meet the needs not only of tomorrow but of the day after tomorrow to devise systems for which there is no immediate use, which will become of permanent importance when a city of two million inhabitants has increased in population by one hundred per cent.

Thus we have seen the addresses of the recipients of the Verkin medal, awarded for distinguished achievements in chemical engineering, must have been struck with the opportunities that await the trained man in that one field alone. Hermann Frasch told how the application of chemical principles enabled him to rid Canadian oils of their sulphur, and thus to make them more generally salable, how he had improved the methods of mining and above all, how he had successfully solved the problem of raising to the surface the sulphur buried beneath Louisiana quicksands, after a dozen men before him had failed to do so. James W. Gayley, an academically trained metallurgist and a former vice-president of the United States Steel Corporation, showed how, with his dry blast process, he had used the waste of one method of producing iron to the advantage of another.

At the International Congress of Hygiene, Chemistry and Textile Materials, held last year in this country, paper after paper was delivered bearing ample testi-

mony to the fact that the trained technologist could make a match for the trained capitalist. The counsel for the greatest sewing machine manufacturing company in this country testified that were it not for the experimental laboratory conducted by three or four smaller sewing machine manufacturers, the company that he represented would undoubtedly monopolize the market. In other words, a handful of highly paid and thoroughly trained technical men were able by their ingenuity to cope with the dominating company.

## PATENT ATTORNEYS

## PATENTS

If you have an invention which you wish to have your own writer fully and freely to make for you, or for advice in regard to the best way of obtaining protection. Please send sketches or a model of your invention and a description of the device, explaining its operation.

All communications are strictly confidential. Our vast practice, extending over a period of more than sixty years, enables us to advise in regard to patentability without any expense to the inventor. Our charges are in fact free on request. This explains our methods, terms, etc., on request on PATENTS, TRADE MARKS, FOREIGN PATENTS, etc.

All patents secured through us are described without cost to the patentee in the SCIENTIFIC AMERICAN.

## MUNN &amp; COMPANY

36-37 BROADWAY, NEW YORK  
Branch Offices, 425 F Street, Washington, D. C.

## PATENTS

For more than 60 years, Munn & Co. have been the leading authority on all matters relating to the securing of patents, trademarks, and copyrights. Our extensive experience and large staff of expert writers and attorneys enable us to secure for our clients the best possible results in the shortest time and at the lowest cost.

Send for our free book, "How to Obtain a Patent," which contains full and complete information regarding the securing of patents, trademarks, and copyrights.

## One of the unique things about the Cadillac is its freedom from rivalry

And this carries with it an astonishing immunity from criticism.

You can confirm this in your own community—wherever it may be.

Cadillac dealers seldom discuss other cars—they do not find it necessary.

Dealers in other cars do not find it prudent to attempt to disparage the Cadillac.

And its most ardent competitors pay it tribute.

This condition is so unusual in any field of industrial endeavor that it will be well worth your while to study the reasons.

You will find those reasons in the features which characterize the car itself;

An engine of 40-50 horse-power which those who know motor car engines recognize as unsurpassed in fineness of construction and in capabilities commensurate with its proportions.

A cooling system so adequate that overheating is ; ractically unknown.

A lubricating system so competent, so simple, so free from annoyance that you scarce realize its existence.

A carburetor so efficient, so flexible that it needs acknowledge no superior.

A clutch so smooth, so velvety in its action, so simple and so dependable that it leaves nothing to be desired.

A system of electrical cranking, lighting and ignition (now in its second successful year on the Cadillac) so nearly 100 per cent efficient that it would be difficult to more nearly approach perfection

A steering mechanism so steady, so safe, and so sure, possessing none of the attributes which might make it otherwise, that you always feel secure.

Axles so strong, so substantial that they are equal to any reasonable demands.

A spring suspension so soft, so flexible, so yielding that it abundantly justifies the popular saying:—  
"The Cadillac carries its own good road with it."

A car, in all, designed with such consummate skill and executed with such painstaking care that it will uphold the name of "Cadillac" and all that the name implies,

a name which stands for sturdiness and dependability,  
a name which stands for enduring service,  
a name which stands for comfort and luxury in motoring,  
a name which stands for economy of operation and maintenance,  
a name which stands for real and substantial value,  
a name which is honored in untinted measure wherever motor cars are known.

CADILLAC MOTOR CAR CO., DETROIT, MICH.

**M**ANY Marmon cars have passed the 100,000 mark in mileage and are still operating quietly, smoothly and efficiently. With reasonable care and attention there seems to be no limit to the service an intelligently designed and thoroughly well-built automobile can give.

Equipped with every modern convenience and luxury, the quality of Marmon service is as satisfactory as its great durability.

*Detailed information on request*

**Nordyke & Marmon Co.**

(Incorporated 1911)

Indianapolis, Ind.

More Than 25 Years of Successful Manufacturing

#### The Marmon "32"

Four cylinders, 32-hp. & 14-hp. wheel base shorter than starting and lighting system. Full-hand steering, semi-coupled axial steering, with control both types in most cases optional. — 2, 3, 4, 5 & 21.55.

#### The Marmon "48"

Five cylinders, 48-hp. & 14-hp. wheel base shorter than starting and lighting system. Full-hand steering, semi-coupled axial steering, with control both types in most cases optional. — 2, 3, 4, 5 & 21.55.

money to the achievements of trained men in modern industry, and therefore indirectly proved the opportunity that awaited the technical graduate. Thus, in discussing the production of synthetic rubber by Harrier and Hofmann, Prof. Dulsberg showed how all the resources, both technical and financial, of a great German chemical company are being used in endeavoring to produce rubber by artificial means so cheaply that the chemical plant can some day compete with the plantation—a work on which dozens of trained chemists have been unwittingly engaged for years. Prof. Berthoulet showed how important has been the aid of the trained chemists employed by the company of which he is the head, in reducing nitrogen from the air, so that the exhaustion of the Chilean nitrate beds, so frequently prophesied, is no longer a cause for alarm. Nearly every one of the papers read before the audience mentioned was prepared by men who are employed by European and American manufacturing companies. They revealed how refined are the scientific methods which are now necessary in carrying out manufacturing processes on a large scale, how hopeless it would be to attain the same result with the aid of men who have not had the benefit of listening to a great teacher in a great technical institution and how increasingly necessary is the employment of the technical graduate in modern industry.

#### Recent Improvements in the Storage Battery

(Continued from page 247.)

cell consists of electrodes of spongy iron and nickel hydroxide in a caustic soda solution. The caustic soda serves merely as a carrier of ionic oxygen and hydrogen and does not become exhausted, so that improvement of the electrolyte is not a serious difficulty, as in the lead cell.

In order to increase the conductivity of the active masses, Edison impregnates both the iron and the nickel electrodes with a benzoin compound. The benzoin reduces to the metallic state in the iron electrode upon charging, thus forming a ducting vessel throughout the mass. He fills, in Sweden, prefer to add cadmium to the active masses. Others have shown the application of the Planté process of electro-chemical formation to these electrodes.

**zinc Lead-Acid Cells.** The migration of zinc for the spongy lead plate can invade itself because of the material in crease in voltage. A difficulty lies, however, in the fact that zinc dissolves during discharge, and in being electroplated out upon charge, it tends to deposit in a porous, loosely adherent mass, and so becomes dislodged from its support. This condition necessitates the use of horizontal electrodes, the zinc preferably being at the bottom of the cell. Numerous modifications of this type are found, in which zinc is combined with various elements.

Morrison shows a number of screens of woven copper wire A (Fig. 1). These screens being silver or copper plated and amalgamated by dipping with mercury. Zinc is electroplated upon this support during charge. The upper electrode B, separated from the lower one by an insulating plate H, may be made of aluminum, copper, silver or nickel. Morrison so proportions the relative quantities of the zinc and the caustic soda electrolyte that only a part of the zinc dissolves, the rest remaining on the support and merely oxidized. Morrison also has found that the zinc is held insoluble by the addition of cadmium.

**Other Battery Combinations.** Perry has a positive plate electrode of nickel and silver oxide, an electrolyte of potassium nitrate and a negative plate of zinc. A combination of zinc, chromium and mercury for the negative plate and mercury and silver oxide for the positive is used by Morrison. He prefers an electrolyte of caustic soda containing chromium hydroxide as a cathodic.

**Representation.** The next exhibits formed in the normal discharge of the lead cell.

**Esterbrook's Falcon No. 648**  
A new fountain pen for the world. The smallest pen for most correspondence, available in 14 sizes. A smooth, reliable pen with large ink-holding capacity.  
Write for illustrated booklet.  
Esterbrook Pen Mfg. Co., New York, N. Y. Canadian, N. A.

The last considerable improvement in these ticket printing machines was the addition of the cash register feature. Such a machine is shown in Fig. 4. In this machine the date is first printed on the back of the paper strip, and this strip then passes between an impressing roll and a printing cylinder. On the periphery of this cylinder are fixed type for printing the general reading matter such as the name of the railroad, station where sold, conditions of sale etc., and also a groove for holding the type bar for printing the destination. These type bars are normally carried by spring pins on two endless bands mounted on two drums. Mounted alongside the type bar carrier are two sprocket belts, one of which, passing around a fixed sprocket wheel on the axle of one of the drums, and the other over an idler on such axle. To the first belt is secured a carriage which slides on a rod mounted parallel to such belts. At the front of the machine are arranged several banks of keys similar to a cash register, these being one key for each station, and such keys being arranged in the same sequence as the type bars on the carrier. When one of these keys is depressed, the carriage is made to clamp the second or power driven sprocket belt at the proper place so as to bring the proper type bar opposite the slot in the printing cylinder. At this point the carrier stops and a device opens the type bar and inserts it in the cylinder while the rotator to print the ticket. When the cylinder has completed its rotation the type bar is removed to the carrier and the carrier is then made to assume its original position.

The end of each type bar is notched in accordance with the price of the ticket to the station and unnotched keys or slides are placed in the notches. The rotator and every time the type bar is used. These racks or slides set in motion the mechanism for use in recording the amount of miles to the station. The recording mechanism, the auditing sheet is made to travel, and each time the printing cylinder revolves, the total of miles is printed on the sheet, and a hole is also punched in the sheet opposite the station to which the ticket is sold.

This machine is operated by a weight motor, and when the weight is wound up and the desired run, the motor is released and motion is transmitted internally to the various parts of the machine for performing the following operations: The proper type bar is brought opposite the slot in the printing cylinder and transferred thereto, the printing cylinder revolves once, printing the ticket on the upwardly moving strip, the type bar is returned to the carrier and the carrier moves back until the type bars are in their proper positions. While this movement is taking place, the registering disks are advanced in accordance with the price of the ticket and the total amount is printed on the auditing strip. Likewise, the auditing strip is punched to the proper place and the printed ticket is cut off.

A new railroad ticket printing machine which is expected to facilitate the sale of tickets has been introduced on the Prussian Government Railroad. The machine prints tickets to all stations, and the ticket seller has nothing to do but to put a blank ticket form into a slot and to set the machine by means of pushing a card carriage so that it will print a ticket as he wishes. The apparatus prints the ticket, also a control slip which has all the tickets that have been printed and sold. The control over the business the ticket seller has been doing is thereby complete. The printing of the tickets takes less time than the hunting for the ready made tickets in the different pigeon holes, for the ticket seller has nothing to do but to take a piece of cardboard from a box at his side, to insert it into the slot and to move two levers.

From the foregoing, it will be seen that such thought and study has been devoted to the development of this class of machines, and while the latest types are decidedly complex, they are not unduly so considering the results accomplished. The

## — Don't pay twenty hands to do the work that can be done by one with the Addressograph

PRINTS FROM TYPE

Your clerks are actually worth ten cents a day while writing and re-writing addresses by hand on envelopes, circulars, statements, payroll forms, etc. You pay them many times the amount to do brain work, so why let them do manual labor? You know that the best type or penman can write about 1,000 addresses a day, and that his work is subject to many errors and omissions.

With the Addressograph a boy or girl can print 1,000 addresses, on anything desired, in less than half an hour—twenty times faster than hand addressing, and, above all, absolutely accurate. Addresses printed on the Addressograph are a perfect facsimile of typewriting.

In addition to great time and labor saving possibilities, the Addressograph affords all the features of a Card Index. It is more than a mere machine for addressing—it is a perfect reference record of your mailing list—it classifies and arranges your address plates to suit the most exacting requirements.

The Addressograph is used in 244 distinct lines of business, so, no matter what the nature of your business may be, others in your line are using it, and we can prove to you in dollars and cents that it would prove profitable for you to use it.

Write today, telling us the size and nature of your lists and your line of business. Then we shall send to you one of our business books which will explain just how others in your line are making money with the ADDRESSOGRAPH.

## The Telescope of Speech

The astronomer, by the power of his telescope, becomes a reporter of the movements of a hundred worlds greater than ours, and the student of celestial activities millions of miles away.

He points his instrument at any spot in the heavens, and his sight goes rushing through space to discover and inspect a star hitherto unknown.

Up to the power of his lenses, his vision sweeps the universe.

As the telescope may be focused upon any star, so the telephone may be focused upon

any person within the range of its carrying power.

Your voice may be directed anywhere in the Bell System, and it will be carried across country at lightning speed, to be recognized and answered.

The telescope is for a very limited class, the astronomers. The telephone is for everyone.

At the telescope you may see, but cannot be seen. At the telephone you may speak and be spoken to, you may hear and be heard. By means of the Bell System this responsive service is extended to the whole nation

## You Can Make This Boat at 1/3 Regular Price

You need not wait a lot of money to buy the boat of your dreams. You can make it at 1/3 the regular price. The boat is made of the best materials and is built to last. It is a real boat, not a toy. It is a boat that you can make at home, and it is a boat that you can make at 1/3 the regular price.

## The Brooks System

You'll find exactly the model you like in the Brooks System. It is a system of building boats that is simple and easy to learn. It is a system of building boats that is simple and easy to learn. It is a system of building boats that is simple and easy to learn.

coupling consists of short spring rods arranged in a circle, something like a lantern gear. This flexible coupling permits the power shaft to find its own axis of rotation. In fact, the power shaft has practically no bearing other than that afforded by its engagement with the governor shaft. The tooth speeds afforded by this system of gearing are one sixth of that now employed in speed reduction gears, and about twice as much work is done the factor of safety being about twice as great at low speed. The gears do not travel over twenty feet per minute.

Another interesting development in connection with this engine is a governor invented by Mr. Clark. The governor can be adjusted so that the speed will either increase or decrease as the load is increased and there is a point of intermediate adjustment which gives constant speed under all conditions. The details of this governor are shown in Fig. 3. The balls of the governor are in the form of two sections, J, which engage a fork K, connected by suitable means to the throttle. The speed of the governor varies as the radius of the circular path of the ball or weight about the axis of rotation of the governor and as the size of the angular displacement of the center of gravity of the ball from the plane passing through the pivot of the ball perpendicularly to the axle. As both of these quantities are variable, Mr. Clark has no design for his governor that the variation will be equal through a considerable arc of travel of the weight. This he has succeeded in doing by placing the center of gravity of the weight at such a position that at any given speed the torque or tendency of the weight to swing out varies directly as the displacement of the center of gravity of the weight from the theoretical neutral position. In the Clark governor the fulcrum of the governor ball is 2.5 times farther from the axis of rotation than the distance of the center of gravity from the fulcrum.

## Be Insurance in Switzerland

THIS latest of the diversified forms of insurance applicable to rural life and industries is the insurance of bees against foul brood, now in successful operation in Switzerland. This dread disease, which is due to bacteria of extraordinary vitality is extremely infectious. A hive in which it occurs is a source of danger to the whole neighborhood, since it is sure to be plundered by bees from other colonies which carry the diseased honey and comb to their own hives. It is, therefore, a matter of great importance to the community that such hives should be promptly dealt with in the usual way, the combs removed and burned, new combs started and melted down after a few days, and the empty combs left disinfectant.

In order to minimize the loss in such cases, the Swiss Beekeepers' Association decided a few years ago to establish a system of foul brood insurance to be compulsory upon all the members, about 7,000 in number. The beekeepers pay a premium of 5 centimes (1 cent) a hive. In return for this they are guaranteed free treatment of infected or suspected hives, instruction and assistance in disinfecting, and compensation to the extent of 75 per cent of the value of hives and combs destroyed by the insecticide. As a further means of protecting members, persons who are not policy holders are also aided and were, until recently indemnified for 50 per cent of their losses.

In December, 1909, the Swiss government decided to take over the duty of inspecting and treating diseased hives and the association was thus relieved of much expense. Moreover, as all beekeepers are now obliged by law to notify their hives when infected the association has no longer a motive for indemnifying non-members and has ceased to do so.

In 1911 the number of hives insured was 108,170, most of foul brood, 114, and the expenses of the organization, including claims paid, exceeded the premiums by \$42 francs—a trifling loss for a mutual insurance society.

## Scissors That Stay Sharp

Keen Kutter scissors and shears are shaped and adjusted so that the points always meet true and cut clean. The patent nut and bolt absolutely prevent the joints from becoming loose. Stay sharp, right and accurate after years of service. Made in all shapes and sizes for all purposes.

## KEEN KUTTER

## Scissors and Shears

are scientifically designed and made of the finest crucible steel. Every article sold under this trade mark is a positive guarantee of satisfaction or money back from your dealer.

## The Control of the Mississippi River

THE volume of correspondence which has reached this office since the publication on February 15th of our editorial on the problem of the Mississippi River proves that the magnitude and pressing importance of this question is appreciated not only by residents of the Mississippi Valley but increasingly by the nation at large. We believe that before very long it will be understood that the regulation of a natural waterway that flows through the heart of the continent is surely of equal importance to the construction entirely outside of our borders, of an artificial waterway, such as we were built in Panama.

We draw attention to a letter from the general subject of Mississippi River control printed elsewhere in this issue which draws attention to the fact that those who are interested themselves in the problem are to be grouped broadly into two parties—the one believing that it is possible to regulate the Mississippi at properly selected levees, the other holding that the best results will be obtained by a combination of dams for the storage of floods at the head of the Mississippi and its tributaries with a system of levees in its lower reaches.

In the editorial referred to we stated that those who believe that it is possible to control the Mississippi by building vast reservoirs near its headwaters have failed to appreciate the magnitude of the work involved and the enormous sums of land that would have to be condemned for the purpose. It was shown that Government measurements, taken at the height of the recent flood proved that at our particular point the river was flowing at the rate of 2,000,000 cubic feet per second—a maximum flow which is equal to twelve times the amount of water that passes over Niagara Falls.

These figures of total quantities are sufficiently large to prove that the regulation of the river in reservoir construction alone would be impossible, even if the existing levee system were maintained at the present grade line. As between regulation by carrying the levees to a height that would absolutely control future floods, or building the levees to a lower height and constructing reservoirs to hold back surges of the flood waters, there is of course a difference in cost and time of construction which could only be determined as the result of accurate surveys and estimates. We do know that the army engineers, with their long experience and a vast amount of accurate data at command have made an estimate for complete control of the river by levees, of about \$70,000,000 for the levee work and about \$80,000,000 for the reservoir to hold the levees off, a total cost for the whole work of \$150,000,000. Whether it would be possible to make a serious reduction in this total by holding back a certain portion of the flood waters is a question upon which it is foolish to engage in any mere guesswork. There is at least a strong suggestion that any reduction in cost so achieved would be in the light of the statement of Col. Towson before the House Committee, that if it had been possible to destroy the whole State of Minnesota that it would not have been a difference of three tenths of a foot in the height of the last flood at St. Louis. Furthermore, a reduction of three or four feet in the height of the flood by conversion of the Mt. Pisgah Basin into a storage reservoir, would have called for the sacrifice of some seven thousand square

miles of country. Nevertheless, we believe it would be good policy to have estimates prepared as to the relative economies in time of completion, benefits conferred, and total cost, of a pure levee system as against a levee-and-reservoir system.

Referring to the statement of our correspondent that in the year 1737 a two-foot levee was ample to protect New Orleans from the floods, whereas in 1912 twenty-two feet were registered at the same city, we wish to point out that the difference may be regarded as being in a certain sense an equivalent tribute to the industry of the American people, in bringing into subjection the virgin lands of the Mississippi basin. Two centuries ago the melting snows and heavy rains were returned in their flow from the higher to the lower levels by vast forests and thickly interlaced undergrowth which have since been cut down and cleared away, and the flow of surface and subsoil water into the streams has been facilitated by the open ditch and the subsoil drain. It is quite possible that if two graphic curves were developed, one representing the rate of population in the Mississippi watershed, and the other the increase in height and volume of the Mississippi floods, there would be found to exist a surprisingly close relation between the two.

## What the Rich Man Might Do for the Scholar

LIBRARIAN libraries is a favorite pursuit of philanthropists. This proves that many benevolent persons prefer to minister to the mental needs rather than the material needs of humanity, a preference with which we are not disposed to quarrel. Just because, however, we heartily approve of libraries, we deplore the fact that the amount of money spent in creating them is out of all proportion to the amount spent in making them useful. A library is still a library, even though its contents are securely locked up from human sight, as in the case of the precious manuscripts said to be stored in the crypts of St. Sophia, at Constantinople. The admirable science of librarianship, which has been mainly evolved within the past half century, has for its main purpose the removal of the invisible bolts and bars that obstruct access to libraries. Modern printing and manuscript methods, the use of catalogues, indexes, bibliographies, and the like have immensely facilitated the use of the great collection of books of which our civilization is so proud, but there is still an almost unlimited amount of work to be done in this direction.

Here is a suggestion for the rich man who wishes to vary the programme of library building. A library is primarily beneficial only to a restricted community. The benefits of good work in the bibliography are universal. Why not endow a bibliographical institute?

## Gustav de Laval

IN his book *Great Men* Prof. Wilhelm Ostwald has made a scientific study of the life-history of the great men of science as a specific type of man. There is no doubt that such men do represent a specific type, or perhaps rather a number of specific types. Gustav de Laval, whose death was recently announced, was a striking example of the typical inventor, a mind ever busy on the solution of problems, a man who had no problems because he cannot help himself. Thus it came that not all of his inventions proved commercial successes, and those that did, enriched others perhaps more than their originator. It has been estimated that Laval early solved the problem of steam turbines, and his parents wisely directed his education toward an engineering career. He entered the technological department of the University of Uppsala in 1893, and three years later graduated with distinction. Then came a short period of practical experience in an iron mine and with a waterworks builder, followed by a post-graduate course at Uppsala, leading to the doctorate in 1897. Upon re-entering practical pursuits, he was sent to Germany to make a study of the manufacture of nitric acid, and upon his return to Sweden he built the first sulphur burners in his country. Later he became constructing engineer at an iron works, where he introduced various improvements in galvanizing, the production of steel, and the extraction of iron from iron ore.

The idea of the de Laval steam turbine came to him in the course of an experiment in sand blasting. The breaking force of a steam jet was the fortunate accident which started the train of thought. An engineer,

also, it was that led him to his other great invention—the artificial cream separator. There was a large dairy on the Iron works estate where de Laval was employed, and so, not unnaturally, the milk one day turned upon a new milk separator reported from Germany. It consisted essentially of a rotating bowl, in which the milk was placed. Centrifugal action hastened the separation of the cream, which was finally skimmed by hand as usual. This crude device formed the nucleus of de Laval's automatic centrifugal separator, in which the cream is directed into a continuous stream from the rotating vessel. Such was de Laval's sense of honor that he refused to sell his invention until he had first given an option to the inventor of its crude prototype. As the latter, however, did not avail himself of this offer, de Laval proceeded independently with his own device.

De Laval was a great inventor, but he was more—he was a man of great character. His patriotism took the practical shape of service rendered to the State as member of the Lower and of the Upper House of the Swedish Parliament. From these activities he retired in 1900, finding that, after all, his best qualifications lay in other directions.

Sweden is justly proud of a noble list of great men, the great, and this list not the least is the last great engineer and inventor, Carl Gustav Pehr de Laval.

## Germany's Aeronautical Weather Bureau

THE first storm warning service for aeroplanes on a national scale was that established by the German government at the beginning of the year 1911, as fully described in the article *An Airman's Weather Bureau* in the *Scientific American* of July 29th, 1911. Since that time the service has been in operation over two years, and has amply justified its existence. Its history up to date is given in the last annual report of the Lidenberg Observatory, at which the service has its headquarters.

Beginning with last year in addition to the center at Lidenberg, a second central station has been maintained at Frankfurt-on-the-Main. The principal pilot balloon stations are Aachen, Frankfurt, Hamburg, Magdeburg, Berlin, Breslau, Kasselberg and Bremen. These are provided with large balloons, each reaching an altitude of from 2½ to 5 miles (according to the size of the balloon) in about 40 minutes. Second air stations, equipped with smaller balloons, are located at Brumberg, Dresden, Jena, and Weimar. Balloon stations are also maintained at various other central stations at Strassburg, Friedrichshafen, and Munich.

The telegraphic reports of upper-air observations received at the two central stations are combined with the ordinary low level weather reports collected at the Deutsche Wetteramt, in Hamburg, and enable the authorities to issue twice-daily forecasts which state in very definite terms the conditions likely to be encountered by aeroplanes at various levels for a few hours in advance. The forecasts and warnings are telegraphed to all the co-operating stations, and warnings are also telegraphed or telephoned directly to individual aeroplanes and institutions that request them and are willing to pay a small fee for this service, in addition to the fee for the forecasts.

Probably the most important development of the aeronautical weather bureau since it was established is the system of reporting thunderstorms. At first the attempt was made to utilize the service of a number of the ordinary low level weather stations, but owing to the meteorological institutes. This plan was not successful, as a great many observers did not live near enough to the telegraph offices to send their reports promptly—and delays are fatal in an undertaking of this character. Accordingly, with the approval of the postal authorities, a new corps of thunderstorm observers was organized among the 32 and 34 class postmasters (who are also telegraphers) in 1912. The number of these observers, all of whom give their services gratuitously, was 100. In addition, 18 important offices in large towns, which are the centers of the main telegraph lines running in all directions, report disturbances on the lines indicating the occurrence of electrical storms. The fact that reports from postoffices are treated as "service messages" insures prompt transmission, which is further promoted by the fact that the Lidenberg Observatory has a private wire from Berlin. By these means German meteorologists appear to have solved the important problem of giving accurate timely warnings of all the independent sources of information, which is the most important of the meteorological institutes. In fact, these stations were in a general direction from west to east, and frequently assume the form of line-squalls, i. e., long areas of disturbances moving sideways across the country.

From all the stations of the service of the last two years in Germany, including the army observers, have made the fullest use of the new weather service, and it is now looked upon as an indispensable institution.

How the hood collapses into the frame of the body

The queer, rounded protuberance at the rear serves as a storage receptacle for spare tires.

The frame of the hood fits into the lines of the car.

### Frank French Automobile Bodies

IN THE SCIENTIFIC AMERICAN for March 1st, 1913 we published an illustrated article on some remarkable automobile bodies which have recently made their appearance in France. On this page we publish some additional views which will reveal the purpose of the curious bumps and ridges that have undoubtedly attracted the attention of our readers.

The accompanying engravings tell their stories so lucidly that it is almost unnecessary to add any text. Suffice it to say that the tendency is becoming increasingly manifest both in this country and abroad to produce automobile bodies which, like the hull of a ship shall be as free as possible from excrescences and protuberances. Tool chests, gas tanks, tire cases and all the other impediments of the running board will eventually be concealed. The running board itself will disappear in the Duret-Mory car, the Griffault body has manifestly been designed with this purpose in view. The old running board becomes the bottom of a casing in which luggage can be stored. Tires are concealed in the rounded protruding rear end of the car. The hood is made so completely collapsible that even its frame disappears, becoming or rather fitting nothing into the lines of the body. The head lights become part of the mud guards.

While we cannot altogether admire the car as it is revealed in our illustrations, it would be idle to deny that an important step has been taken in departing from the traditional type of automobile body—a type which as we still manufacture it bears unmistakable evidence of having descended from the old horse-drawn pleasure vehicle.

Six Wheeled Omnibus  
By Stanley Potman, M. E.  
WITHIN the past few weeks there has appeared on the streets of New York a motor omnibus mounted on six wheels. The vehicle is similar to those used in the streets of London, which were designed by Henry B. Moleworth, the first man to introduce the heavy truck construction in road vehicles. However, the New York omnibus differs from Moleworth's in several important respects.

Moleworth's principal object was to obtain side-slip which up to the time of his invention had been the bane of the manufacturer. It did this probably in lack of experience in the construction of heavy vehicles and also in part to the peculiar work for which the buses were intended. In this new vehicle the reduction of side-slip has been made a secondary object and follows as a natural result of the greater tire surface in con-

tact with the road. The prime consideration was to increase traction and reduce vibration.

In Moleworth's omnibuses there are three pairs of wheels, one pair being at the front as usual, and the other two pairs being at the rear, the arrangement was much the same as that depicted in the accompanying picture. There is this difference, however. Whereas Moleworth drove only the center pair of wheels and

in effect levers of the second class, when arms are of equal length and partake of the functions of these devices, which is to say, when one end of the lever is elevated, as is shown in the accompanying picture depicting the vehicle with one pair of the wheels on the road surface and the other pair on the curb, the total vertical movement transmitted to the main axle is only half that sustained by the end of the

lever. The net result of the arrangement, of course, is that a great amount of vibration due to irregularities in the road surface is eliminated.

The drive is transmitted from the engine through the intermediary of a master clutch and an orthodox gear set to a jack shaft and thence to the front pair of rear wheels through side chains. From the front pair, side chains transmit the drive to the rear pair. As both pairs are equipped with brakes, the brake capacity is double.

The inventor claims that as the pairs of wheels are smaller individually than would be the single pair, the added cost is purely nominal and need not exceed \$100. This, it is pointed out, would be more than offset by the saving in tires, because twice the surface is in contact with the road as would be with the ordinary vehicle.

The second objection is based on the difference in direction of the pairs of driving wheels when the vehicle is turned sharply. But as the distance between wheel centers is short—in practice it is 25 inches—the actual amount of difference in direction is small at best and is more than compensated for by dissipation of the rubbing stress.

The old mudguard becomes the bottom of a casing for the storage of luggage.

View showing chain connection of the two pairs of rear wheels.

Flexibility shown by backing the rear wheels upon the curb.

Six-wheeled motor omnibus recently introduced in New York.

### Stereoscopic Views of Lightning

By the Berlin Correspondent of the Scientific American  
In the year 1887 the Royal Meteorological Society of England addressed a circular to photographic societies and individual photographers throughout the world requesting them to furnish the society with photographs of lightning flashes. About sixty photographs were secured, and an examination of them made possible the first accurate classification of the forms of lightning.

In 1889 Mr. Mariotti, assistant secretary of the society, published a set of rules for photographing lightning. The same year Weber, in Germany, and Hoffer, in England, independently devised a method of analyzing a compound lightning flash, viz., by the use of a camera revolved slowly in a horizontal plane. This was an immense improvement upon the non-photographic methods—entailing the use of various forms of the revolving disk—which had led earlier investigators including Arago, Dove and O. N. Rood, to conclude that many lightning flashes are multiple and had enabled them to form a rough idea of the intervals between the successive discharges along an identical path which give such lightning a flickering appearance. Moreover in 1890, A. W. Clayton in England, cleared up the mystery of "black flashes" in lightning photographs by his discovery of the "Clayden effect."

Since 1890 the progress of lightning photography has been due chiefly to improvements in the technique of the moving camera. One of the pioneers in this field was A. Larsen whose work has been done under the auspices of the Smithsonian Institution. A full account of Larsen's researches was published in the SCIENTIFIC AMERICAN SUPPLEMENT No. 1635, May 4th, 1907. The most successful applications of this method, however are due to Dr. B. Walter of Hamburg, who has made comparative studies of lightning flashes and analogous electric discharges in the laboratory. The greatest improvement introduced by Walter in the photographic process was the addition of a stationary camera, installed alongside the moving camera. A comparison of the two pictures thus obtained enables the investigator to determine the exact relation in time of the various phenomena photographed. The first account in English of this double-camera method and its results is that given in Mr. C. F. Talman's article "New Ideas About Lightning" in the SCIENTIFIC AMERICAN of June 24th, 1912. (The reader should examine

especially Fig. 3 of the article just cited in connection with what is said below about the use of the moving camera.)

Walter's latest achievement involves the use of a third camera as stated below. The photogrammetric method in lightning photography is not altogether new. It has been applied by McAfee, in this country, among others. Its use in connection with the moving camera

Fig. 1—Stationary stereoscopic camera.

Fig. 2—Movable camera with clockwork.

however, represents an important advance. To complete this sketch of the history of lightning photography it may be added that the first, once deemed impossible, of photographing lightning flashes in the daytime was achieved with remarkable success last summer by A. Steadworth, of Ottawa. Moreover, the present writer has seen the negative of a still earlier photograph of daytime lightning, by L. Glaspé of Paris, made by color photography. Lastly, it should be stated that there is still a great deal of work to be done in lightning photography, and any competent person who takes this subject up is likely to be rewarded with some interesting discoveries. Several peculiar forms of lightning have not yet been photographed. (Continued on page 264.)

### "The Snow of the Penitents"

By C. F. Talman

THE traveler in the high Andes of Argentina and Chile is sometimes greeted with the startling sight of what appears to be an innumerable throng of kneeling white-robed figures upon the barren mountain side. The nearest known human habitation is scores of miles away, the region to which the traveler has penetrated

is one in which on account of altitude, a polar climate prevails, and mountain sickness afflicts even the hardy. In short, no more unlikely spot could be found for the existence of this fantastic company.

Closer inspection dispels the mystery—only to replace it with another. Each of the figures is found to be a block of snow or ice, brought into its form such as are here assumed by frozen water in any other part of the world. The resemblance of the figures to human beings engaged in some solemn religious ceremony has led the natives of South America to call these strange, hummocky snow drifts in *nieve de los penitentes*, the snow of the penitents—an expression that is often shortened to *nieve penitente*. The Germans, with their characteristic aversion to exotic terms have translated this name to *Bessenschnee*, but English writers have been contented with the Spanish form.

How does Nature fashion these grotesque figures? And why are they found only in a limited region of the Andes? These questions have not yet been satisfactorily answered.

The *penitentes* occur only in low latitudes, hence under a sun that is almost vertically overhead at least twice a year. Perhaps the first impulse to their formation is a sheet of new-fallen snow in of uneven density. The powerful solar rays will speedily form depressions around the denser spots. As the snow continues to melt, the water trickling down from the mounds helps to deepen the hollows, as it is prevented from accumulating in the latter by the slope of the mountain. The arrangement of the figures in regular rows is also explained by the slope, the water all draining in one direction.

Perhaps the first impulse to the formation of mounds and hollows is given by the wind, which, as everyone must have observed often blows the surface of a field of snow into waves and ripples.

There is another possible explanation. A well known expert of Benjamin Franklin was to his late days, cloth of various colors upon the snow on a sunny day,

Figs. 3 and 4.—Stereoscopic pictures of lightning flash taken by two stationary cameras.

Fig. 5.—The same flash taken by a movable camera.

Foot of Mount Fitz-Roy.

Fellera's Glacier

Rio Blanco Valley

"The Snow of the Penitents" (Nieve Penitente) of the Chilean-Argentine Andes.—(Photographed by Dr. F. Reichert.)

he observed that the cloth soon became heated and sank into the snow; the darker-colored pieces sinking more rapidly on account of their greater power of absorbing solar radiation. Patches of dust would have the same effect. Dust is found even on the highest mountain tops, most of it being carried from the atmosphere at the foot of the mountains which are constantly entering our atmosphere from outer space. The wind might easily blow a layer of this dust into a sort of checkered pattern and thus it would, when heated by the sun, resemble the unbroken snow. Plausible mistakes could arise from one or another of these processes and find not only in the Andes, but in the Alps and the Hinduayas and probably elsewhere. However, travelers who have seen the *periwinkle* claim that they are quite distinct in appearance from the snow, because seen on other mountains, in which case they must be conditioned by some local peculiarity that has not yet been explained.

The photographs accompanying this article were taken by a leading authority on alpine geology, Dr. P. Richert, of the University of Buenos Aires.

### Compressed Air as a Protection for Battleships

By R. G. Skerrett

**T**he serious consequences of a stumble upon a submarine mine, the chance, perhaps, of having one of our super-torpedoed battleships, or even a dreadnought, by a single submarine blow, led our naval authorities to undertake a novel experiment more than a year ago. That experiment constituted the equipping of the armored cruiser "North Carolina" with a self-contained salvaged outfit by which in case of emergency to serve as the medium by which the lurching sea water could be quickly driven outward again and the damaged compartments substantially drained a few moments after an accident.

The test equipping of the "North Carolina" has proved so satisfactory in a number of ways that this system is to be installed hereafter as a regular feature upon the mightiest ships of our battle line, and this is especially the case with the peerless "Pennsylvania."

Mr. W. W. Waterhouse is the engineer inventor of this system, and this application of it is really the outcome of his work in connection with the last effort to subvert the cruiser "Tanquer" in the case of the scheme to turn the water-tight compartments into a calson, as it were, and by the admission of compressed air first to pump the water out from the wound end chamber and then to keep it out by a sufficiency of compressed air. In other words, the water must become like an inverted tumbler in a bucket of water—the tumbler being tilted before inversion. Thus by forcing air in through a hole in the bottom of the glass the water is expelled. In the case of a ship, however, the water enters by a hole in the bottom, passing through one cause or another, and steps must be taken immediately to offset the stresses of this leakage before the gathering pressure ruptures the caulking bulkheads. By the ordinary procedure, the ship pumps try to hold the invading water in check, but infrequently, this is tantamount to trying to pump out the whole sea. Even so, the dividing walls of steel may slowly yield and the vessel is frequently doomed.

If Mr. Waterhouse's system, not only is the incoming water forestalled against the water-tight bulkheads are given immediate and temporary support, which effectually localizes the injury. He accomplishes this by putting his heaviest air pressure immediately in contact with the water to be expelled, and he surrounds the injured bulkhead with compressed air, and, finally, he takes the excess of pressure from these supporting compartments by admitting air of still lower pressure to other flanking and superposed compartments. Thus by a successive distribution and reduction of the air, none of the bulkheads or decks is overstrained. This idea of dividing the internal body into succeeding layers or strata of compressed air is one of the unique features of the system. For all ordinary contingencies, the highest pressure would not exceed 14 pounds in the water-tight bulkhead and the lowest pressure would be in the neighborhood of about 4 pounds to the square inch. We have shown in the small diagrams two strata of different pressures and have marked them 1 and 2.

At first blush it may be imagined that the installation of a system of this sort would involve a costly increase of weight and much additional apparatus. As a matter of fact, the whole equipment is remarkably simple and easily put in place. This is because Mr. Waterhouse has taken advantage of the fact that the ships are already a part of the modern fighting ship. Every compartment is provided with two lines of piping: one to force fresh air into the space and the other to provide an exhaust for the foul air or gases. These pipes may be so strong enough to stand a pressure of several times the limits, and these limits are considerably in excess of Mr. Waterhouse's requirements. He merely takes

such of these pipes as he may need and connects them to a supply of compressed air. Pretty nearly every man-of-war—certainly all of the big ones—have air compressors aboard for other purposes, and a reserve can very easily be stored in a suitable reservoir and at the service of the compressed air system. This reserve may be used in an emergency to connect the ventilating pipes of any of the compartments with the compressed air in reserve and then to start the compressors in order to maintain a further supply. The facility with which a flooded compartment can be drained and the reserve in the supporting spaces brought up to the proper degree has been convincingly demonstrated in actual service, both in cases where the flooding has been intentional and where a leaky sea valve has produced the trouble.

According to the building specifications, every watertight compartment of a fighting ship is supposed to be tested at some time during the course of its construction, but because of the complex get up of these craft and the very intricate of some of the mechanisms, it is practically out of the question to flood these compartments. Accordingly, those spaces which should be watertight are sometimes not so, and the fact is not revealed until accident perhaps reveals that disturbing fact. This is not all. The settings of watertight doors become imperfect by use, and the extent of this weakness is frequently overlooked, and leakage might be of grave moment should the continuous space be inundated. Mr. Waterhouse's salvage system provides a perfectly effective means of testing every compartment and every watertight door at any time, and makes it possible to do this without damage to the contents of any of these spaces. The practical value of this inspection agency has been amply demonstrated, and it is hoped that our builders to do this more intelligently and more thoroughly in a number of cases where flanking compartments become flooded, compressed air was turned into neighboring spaces filled with valuable stores, and the water held away effectively.

A logical development of this safeguard against the foundering of a wounded ship is that of suppressing or smothering fire. For such a contingency, Mr. Waterhouse again makes use of the ventilating piping, but instead of forcing compressed air into the water-tight division, he pumps down through the pipes a volume of non-inflammable gas. Carbon dioxide has been tried for this purpose before, and this has been drawn from the fire-tanks, but this is not desirable, and in fact is not sufficiently available in quantity for the purpose of extinguishing fire. Therefore Mr. Waterhouse will use another gas which can be quickly generated in large quantities. This gas will not damage stores or merchandise, the advantage of a check on fire of this nature must be fully apparent and can easily be seen. The lowest time avoided instead of using water. Apart from this, water is not always an effective extinguisher, whereas a suitable non-inflammable gas is when made effective against gases wherever there is a fire. The suppressing of fire upon a man-of-war is pretty nearly as vitally important as that of promptly arresting a leak, in fact, there are times when this may be a matter of desperate concern.

### Revelations of the Boston Automobile Show

**N**ot only is the door of the really big automobile show open, but the doors of the annual Boston exhibition have been closed this week, and manufacturers at length can draw breath free from the apprehension of show cars. It is most to take stock of the way by which of ascertaining if possible just where in the business of such exhibitions lies. Probably the true state of affairs never will come to light, though an extraordinarily clear vision scarcely is needed to see that the automobile show as a show has almost, if not quite, outlived its usefulness.

It long has been known that these annual functions cause unrest in the bosom of the manufacturer. Obvious symptoms in the bosom of the dealer are only rendered less acute by the hope of increased sales—some day. To the dealer, however, that same day does not come now as it did in the past. It does not come as shiny cars exhibited together under a common roof where the human spirit of restlessness and curiosity induces constant search for something newer to look at, to occupy a mind so readily cloyed with too much novelty and too much noise. Cars are not sold that way now.

It is a comparatively well known fact, to salesman at least, that satisfactory sales from his own point of view and from the point of view of the purchaser demand comparative quiet, freedom from hurry, haste and a more suitable atmosphere than that afforded by the automobile show. Hence, the dealer does not, as a rule, hold the show with delight. It disrupts his sales and interferes with his business. Just as it disrupts the sales and engineering forces of the manufacturer, so it disrupts the sales of the dealer, it is only after heated argument, and

as a measure to prevent indignant promoters stepping into the breach that would be left, that it was decided to hold the usual shows in 1914. Whether they will be repeated in 1915, which is quite a long way to look ahead, remains to be seen, but if present sentiment can be taken as an indication, the repetition is unlikely.

The public wants the shows, of course. They furnish excellent excuses for the display of the family jewels and permit practices in politeness up to the manner that go with a successful social display. But the car-buying public cars bought for such things in the majority of cases. Hence, the influence of the automobile show in increasing sales is questionable, to say the least.

Similarly, as exhibitions pure and simple, the shows which logically are for the exhibition of new cars fall far short of the average expectation. Cars which are shown already have been on the market for several months in case cases out of the proverbial ten and little—very little—actual novelty is revealed. At the Boston exhibition, for instance, there were just five brands of cars out of a total of some hundred makes on view that had not previously been shown either in New York or in Chicago. Two were gasoline propelled, two were electric and one was a steamer. It is almost impossible to say how many of the cars were new, but the fact is that the shows are of little or no use in increasing sales in these days of steadily increasing efficiency is all the more remarkable by reason of the fact that its engine consists of two simple cylinders and that no condenser is used.

In the realm of motorcars, the Boston show was no more productive of newness than it was in the realm of complete cars. Two engines appeared, heralded as being new, though in both there was apparent plain indication of well known principles. In use the valves are in the side of the cylinder and the connecting rods are in the side of the cylinder proper, and in the other the usual poppet valves are replaced by longitudinal rotating sleeves which alternately cover and uncover cylinder ports. In neither, however, has the designer given evidence of deep thinking with regard to the likely effect of an equal cylinder distortion due to the presence of irregularly shaped castings with comparatively large masses, almost directly at the spot where the greatest heat is generated.

The single really significant feature of the show was in the form of a magnetic gear shifting device with which one of the cars was equipped. Pressure on any one of a series of five buttons, corresponding with the four forward speeds and one reverse speed, permitted any of the five speeds to be shifted without attention on the part of the driver than the release of the clutch. In view of the widespread adoption of electric lighting and engine starting devices and the general tendency toward the elimination of manual work, the presence of this device may well be viewed as significant, particularly inasmuch as it now is pretty well established that at least one well known American car will be equipped with a device of the kind before the end of the present year.

### The Current Supplement

**T**HE new issue of our Supplement brings the concluding installment of Mr. Waterhouse's report to the Inventors' Guild—much time may be saved and efficiency gained, by employing judicious means in selecting machine designs preparatory to the execution of complete drawings. Mr. Ford Haring gives our readers some valuable hints in this matter—Dr. R. J. Russell of the Rothamsted Experiment Station gives us a survey of the present views regarding the effect of soil sterilization upon plant growth—Mr. F. I. Coleman tells us how the living line, the world's most treacherous, changed its course nine times in 2,000 years, has been reversed upon the railway bridge—Mr. A. & Neumann contributes an excellent article on Perceps and Persals—Mr. R. Obering, in a richly illustrated article, describes the process of development—Mr. Carnegie reports on a study of the vibrations of the lateral wall of the eye by the aid of instantaneous photography—Dr. R. C. Osburn gives us an interesting talk on the Crayfish. It is not generally realized that this crustacean has considerable food value. In yet the annual catch in the United States amounts to \$24,000.—An Extract from Lloyd's Official Report for 1912 will interest those of our readers who follow the development of the world's shipbuilding.—A comment on the Friedman treatment for tuberculosis should prove of timely interest.

**Old Trees Make Successful Spinebrakes.**—As the result of a series of experiments which recently were held in Peck, it is intended to use the trunks of the most successful devices employed were merely old trees cut up and fastened to the ends of the wheels. On the whole, the tests proved to be a failure, but the study was not without interest in showing that the

## The Buggy as a Destroyer of Roads

To the Editor of the SCIENTIFIC AMERICAN

Mr. Arthur C. Brady is in the right in his article in your issue of January 18th, 1913.

I have made the same observation during many years, being led to do so by my work as a teacher of surveying and engineering.

Horses do most damage to the roads, and narrow steel tires come next. Any gravel or stone road in Indiana bears evidence of the above. Unless the former is dragged in suitable weather, which may not occur during an entire season, it soon has three deep grooves, two for the wheels and one midway between, formed by the horses, driven single. The last is most difficult to control. It is due mostly to rapid driving. On hills, where the horses walk, it is not so common.

Our farmers complaint of automobiles ruining the roads, but the man in a buggy, with his fast-trotting horse, is a greater menace. There would be greater complaint if in taxing vehicles to raise a road fund, the horse-drawn buggy should be taxed as a motor car, and speed limited to four miles per hour, a rate that would do but little damage to the road. So far as I know, that has not been done in any State. The autolast is taxed because they think he is able to pay. Most men would like to avoid, greatly to his credit. While that is true, the facts as to road wear ought to be understood.

Danville, Ind.

## Spring Wheels

To the Editor of the SCIENTIFIC AMERICAN

Referring to article by Mr. Dennis which appeared in your correspondence column in the issue of March 1st, I wish to state that it was my intention in my previous communication to point out a principle which must necessarily be involved in any spring wheel, whatever may be its construction.

Mr. Dennis's statement that "the highest type of spring wheel requires all of the springs to assist equally at all times in carrying the load" is correct. But it is evident, if we consider any given spring, first in a position below the hub and second in a position over the hub, that the flexure of the spring in the two positions must necessarily be in opposite directions, and of amounts equal to the flexure produced by the load, thus giving a normal flexure in each direction at every turn of the wheel.

The normal load flexure and the shock-absorbing capacity of the wheel will each be inversely proportional to the strength of the springs. It therefore follows that if "when the wheel is operated over a perfectly level road the springs are not flexed in the least degree," then the shock-absorbing quality of the wheel has been reduced to a minimum by the great strength of the springs.

The question involves a mechanical principle on which I had hoped to obtain an unbiased opinion, more particularly as to whether the present high quality of spring steel was capable of withstanding such a great number of flexures.

Plainfield, N. J.

## Machining Granite Blocks

To the Editor of the SCIENTIFIC AMERICAN

In the correspondence column of the February 22nd issue there is a request that you call the attention of the inventors of the country to the need of a machine to make granite paving blocks, and in acknowledging it you state that "it should not be difficult to devise suitable machines for doing this work."

After years of experiment with different machines, the tried to do the work in competition with hand labor, we certainly would be glad to hear of any such machine and could use scores of them. Further than that, any plan presented that seems feasible we would consider and would finance the construction of such a machine and pay liberally for its use.

We would appreciate the name or names of any firm, inventor, or otherwise to whom this proposition might appeal, so that we would take the matter up with them direct.

## Shaping Granite Cubes

To the Editor of the SCIENTIFIC AMERICAN

In your correspondence column, February 22nd issue, page 176, headed "Required, a Machine for Shaping Granite Cubes," I read something like some shape.

In 1900, at Providence, R. I., I saw a planer similar to that used in the machine shop for planing metal, planing granite slabs with a tool also similar to that used on the same kind of planer in the machine shop. A pipe with water coming out of it moistened the tool, drop by drop, as the stone passed down beneath it. In each pass of the tool a granite slab was being turned in the lathe. I would suggest that the work could be done just as readily on cubes as on slabs, and that the job would depend upon the speed used only. I would also suggest that the job could be done in an economical manner on the ordinary machine-shop lathe or vertical planer, with a machine with a fly cutter. This would be faster than the planer, as no time is lost in the return motion. The fly cutter is made up of a disk having several inerted tools, which may be removed when necessary to grind. The disk turns in a horizontal plane. The cube could be held in the ordinary vice chuck, and a stream of water or oil used to keep the tools cool. The speed should be no faster than what the tools will stand, the depth of cut and feed would be determined by the breakage of the particles of stone. A faster method yet would be to use a vertical grinding machine or surface, as used in the machine shop, using a very coarse wheel. It would then be a simple problem in abrasives, which the Norton Emery Wheel Company of Worcester, Mass., could no doubt solve for you in a very few hours.

Pittsfield, Mass.

## Audible Railway Signals

To the Editor of the SCIENTIFIC AMERICAN

In regard to the matter of an "Ideal Automobile Train Control," on which a correspondent writes in your issue of February 15th, I would like to suggest that, as to avoiding passing a signal set at danger, the absolutely certain method of invariably providing this (so long as the block system is in order) is very simple indeed, namely, instead of visible signals have audible ones, for instance, instead of an arm being thrown into a certain position at the side of the track, arrange a trip in the track, which when set at danger, automatically would ring the bell of the engine, or a special one for the purpose, or blow the whistle in some peculiar way, say a half-minute long blast, so that the engineer, the fireman, but the conductor and the driver, as well as passengers, could plainly hear the danger signal, and if the train was not immediately slowed down to a "walk," or stopped by the engineman, the conductor or some one else on the train would be sure the train was soon due to hit the signal, or a obedience to the signal, for "self-preservation is the first law of nature."

Such an audible-signal system could probably be installed much cheaper than an automatic-stop system, and it would be much more complete and expensive and would therefore never be generally adopted, and which is open to various other objections, such as sometimes stopping a train with dangerous suddenness at a turn, causing excessive "wear and tear," getting out of order for no really, etc. Some objection to the present visible-signal system are, that they cannot be seen at all in a heavy fog, the engineman get tired of looking for them, and it has been proved that there are times when a person with ordinary good color sense is unable to distinguish red from green because of a severe cold, lack of sufficient light, etc. All of these, or other causes for the brain not acting clearly. None of these objections, however, apply to the audible-signal system, which must eventually be universally adopted, and it is strange indeed, that it has not been tried long ago. A simple, inexpensive system of it could be made that would ring a bell electrically (but preferably intermittently) in the cab of the engine, thus dispensing with the mechanism operating a block-signal arm or a trip at the track-side, and of course the low expense of a signaling system is the more generally will it be used. Every mile of railroad track should be provided with audible danger signals: the only efficient ones, and in this age of invention there is really no more need of having railroad collisions than for getting without railroad collisions. The present visible-signal systems could doubtless easily be changed to audible.

Livermore, Cal.

EMMA G. STYLL.

[Many of the existing automatic-stop devices are equipped with means for sounding an audible signal in the cab.—EDITOR.]

## Alternative Propositions for Control of the Mississippi

To the Editor of the SCIENTIFIC AMERICAN

Recently you printed an editorial in support of levees as a method of flood prevention and in opposition to any other plan. Through the show of a doubt that editorial created a wrong impression among some of your readers, and for that reason I ask that you print this statement of fact in order that the issue involved be made clear.

Two schools of thought and two sets of men are

now engaged in an effort to induce the Federal Government to solve the flood problem.

One set—the old-school thinkers—are domiciled at Memphis under an organization entitled "The Mississippi Valley Levee Association."

The other set—the new school thinkers—have been for more than a year domiciled at New Orleans under an organization entitled the "National Reclamation Association," which was formed as the "National Irrigation Association" in June, 1880—nearly fourteen years ago.

According to Mr. John Fox, secretary manager of the Mississippi Levee Association, he is advocating a continuation of the "Levee Only" policy, his organization has secured the enthusiastic support of all the railroads interested in flood protection.

The National Reclamation Association, which is advocating the institutionalizing of the river by the Federal Government, and the control of its floods by the Federal Government through the building of levees and reclamation of caving banks, supplemented by the control of the source streams in order that low-breaking floods will no longer be permitted to form, has enlisted in support of its campaign more than 1,000 business men, manufacturers and taxpayers, but no railroad or corporation affiliated with the power site promoters, is contributing to it, or in any way helping, the work of the National Reclamation Association.

In the Salt River Valley of Arizona, the Federal Government has constructed the great Roosevelt Dam, which anchors the freshet waters of the Salt River, conserves them and uses them to irrigate the arid lands of a large territory. Below the dam the Salt River is now peaceful and quiet. The Roosevelt Dam is an illustration of the character of source stream control provided for by the Newlands River Regulation Bill and advocated by the National Reclamation Association.

Down in the Lower Mississippi Valley near Vicksburg Mr. John M. Parker has named his great 15,000-acre estate the Roosevelt Plantation. In May 1912, through the breaking of the Saline levee, this estate was turned, by the river into a mighty reservoir, with enormous loss to the owner, and to much of the land in an area hundreds of square miles in extent.

The Roosevelt Dam Reservoir in the Salt River Valley is an illustration of a source stream reservoir, the Roosevelt Plantation Reservoir in the Mississippi Valley, is an illustration of a source stream reservoir with the river makes for itself when the floods are untrolled at their source.

In the terms of the Newlands River Regulation Bill, its appropriation and working machinery are supplemental to and substitutes for levee work provided for or to be provided for through the Rivers and Harbors Bill.

During the Congress just terminated six million dollars were secured for the Mississippi River between Cairo and the Gulf.

The lowest estimate yet made of the cost of leaving and resetting the banks of the Mississippi between Cairo and the Gulf under the standard of the Mississippi River Commission is \$140,000,000.

Should the "levees only" people succeed in getting the \$40,000,000 asked for by Senator Russell, \$100,000,000 additional would be required to meet the cost, to complete this one angle of the work, an angle which deals with effect and not at all with cause.

The Newlands Bill provides this additional \$100,000,000 and it also provides enough money to largely control the flow of the tributaries of the Mississippi and the Missouri by controlling the source streams of these tributaries. In this way conserving much of the now wasted freshet waters and turning them to use for industrial purposes, and at the same time aiding materially in checking the formation of great levee breaking floods.

In 1717 a two-foot levee was ample to protect New Orleans from floods.

In 1912 twenty two feet were registered on the river gauge at New Orleans.

During these two hundred years the valley has known no effective levee floods other than that supplied by levees which invariably broke in some places whenever the increasingly great floods were poured down on them by the tributaries above.

Nobody down here is opposed to levees, but many people down here have awakened to the fact that levees alone will not keep the river off the farms, and they are now asking that the Federal Government not only build good levees and properly reset the caving banks, but that it implement this protection by harnessing the source streams wherever possible, thereby in part at least, reducing the volume of floods by using some of the now wasted freshet waters for the creation of hydro-electric power, for the irrigation of dry lands and for the feeding of the streams in the dry season in order that there will be water on which to float boats.

WALTER PARKER.

# Measuring the Flow of a Stream

## How Water Powers Are Accurately Calculated

By Richard Hamilton Byrd

IT is one thing to own a waterfall or a power-site capable of producing sufficient hydro-electric power to run a big plant. It is another thing to develop this power and apply it to the wheels of industry or to find some one who wants it badly enough to pay the owner what he considers it worth. The conversion of falling water into cheap merchantable power is always a large and most expensive undertaking. It is true that certain large corporations have of late years been acquiring water-power properties of great extent but that the major portion of the water-power that can be generated in the United States is controlled by a few individuals or combinations, as has been freely stated, is not to be credited. The power which is at present running, to waste in the navigable rivers alone of the United States, which are of course controlled by the Government, must be much greater than all the power that has thus far been developed or projected, to say nothing of the millions of untouched horse-power in the rivers flowing through the public lands of the West which have been reserved by the Federal Government. The chief hydrographer of the United States Geological Survey estimates the developed water-power in the United States to-day in round numbers at 6,000,000 horse-power, but he believes the undeveloped water-power which might be realized from the normal flow is 60,000,000 horse-power. Further he estimates the possible ultimate development through the building of flood storage reservoirs at the tremendous total of 290,000,000 horse-power. It is thus seen that even with the enormous developments which have been going on in recent years we are but at the threshold of our water-power development, having so far utilized less than one thirtieth of this resource.

To obtain a mind picture of what this power means it may be reduced to terms of operating locomotive engines. There are in the United States about 51,000 locomotive engines, and the average engine has approximately 1,000 horse-power. The annual consumption of all the railroads is about 10,000,000 tons of coal. The maximum power from all the streams of the United States would, therefore operate four times the number of all the locomotives of the country if they were running day and night every day in the year, or would do the work about twelve times greater than that actually performed by all American locomotives or represent a consumption of over a million tons of coal a year—double our coal consumption of last year. While these are enormous figures compared with the actual power development to date, there is nevertheless intense interest throughout

work is devoted to all these matters—study of the volume of streams, in low water and in flood, current velocity, gradient, storage, power, irrigation and drainage possibilities—in fact, it makes river surveys, it is the Water Resources Branch of the United States Geological Survey. Since such work was systematically undertaken by the Survey in 1905 Congress has appropriated \$2,023,000 to carry it forward, and the result is that we have now a pretty fair working knowledge of most of our principal rivers and many tributaries. In some years over 1,000 stream gaging stations have been maintained in most sections of the United States. This season the Survey has approximately four hundred such stations in operation, and is doing co-operative stream measuring with States and individuals at as many more.

In the contemplated development of a stream for power irrigation, or any other industrial purpose the first question that arises is: What is the flow, the volume, of this stream? How much water will it deliver in a day in a month, in a year, in a period of years? To what extent can it be depended upon as a never failing servant of man? To answer these questions the Government hydrographic engineers are making their thousands of measurements annually and computing the results for the information of the public.

At each Survey gaging station the height of the river is recorded daily. Then at frequent intervals with the river at different heights, the hydrographer visits the station and makes soundings across the stream bed every few feet so as to get a cross-section of the river bottom. With this cross-section of the body of water and the speed of the flow, usually obtained with an electric current meter lowered into the water, he can readily compute the number of cubic feet of water passing a given point per second. This flow, of course, varies greatly at different seasons. Variation is of the greatest importance in considering the river's flow for both irrigation and power. The low water flow largely fixes the river's value in both cases. If for irrigation it must be known how much water can be depended on during the irrigation season, and if the water is to be stored in a reservoir the total annual flow must be determined. If for power the low water flow largely fixes the value. If a factory is to be run by the power twelve months in the year then the two or three months of lowest water will measure the capacity of the plant. The fact that an ordinary flow may be a hundred times greater, as is the case in many rivers will be of no importance, unless storage reservoirs are provided.

Because the Geological Survey has accumulated a

Gaging car and United States Geological Survey engineer on the Yakima River Washington

TABLE SHOWING IN SECOND FEET THE FLUCTUATIONS IN FLOW OF EIGHT REPRESENTATIVE WATER POWER RIVERS IN 1903—A TYPICAL NORMAL YEAR.

	Maximum	Minimum	Mean
Susquehanna	270,000	5,000	47,500
Potomac	60,000	2,000	12,400
Hopewell	25,700	500	3,000
Savannah	130,000	3,000	17,000
Chattahoochee	15,400	415	1,600
Grand (in Colorado)	17,900	400	2,700
Sacramento	141,000	4,000	19,000
Columbia	103,000	72,200	2,910,000

the entire United States at the present time in the value and the possibility of the country's waters and their utilization for power, for irrigation, for navigation, and for municipal purposes. What study is being made of the great resource in connection with any of these vital problems? What information if any is available to the owner of a water-power to enable him to determine the equity of the price offered?

There is a branch of the Government service whose

Long trolley line and car for measuring the volume of the Susquehanna River.

In rivers that are not too deep the gaging is done by wading in high rubber boots.

great amount of river data, the Government was able during the first year of the adoption of the present water power regulations for the public lands to make withdrawals along ninety-seven west ern rivers, including thousands of water power sites and involving millions of horse-power. To have acquired this information for these withdrawals specially for the purpose would have accumulated an enormous amount of field work, in fact, it could not have been accomplished in a single year with even an unlimited force and expenditure.

This stream measurement work of the Survey carried on throughout the West for many years prior to the passage of the Irrigation law enabled the Reclamation Service to begin its construction work at once and to push it with a rapidity that was the astonishment and envy of visiting British Irrigation engineers who had worked in India and Egypt. It is admitted that the integrity of these great irrigation works in the West, upon which over \$70,000,000 is being expended by the Government, rests upon the hydrographic work of the Geological Survey. The formula for arriving at the horse-power in any river is a simple one. Multiply the volume of the stream flow in second feet, i. e., the number of cubic feet of water passing a given point every second, by the fall of the river in feet and divide by 11. This will give the actual horse-power, which is 80 per cent of the theoretical horse-power. One second foot equals approximately 7.5 gallons thus

Instruments in house give continuous automatic record of the rise and fall of a river which, in connection with the measurements made from the gaging car, furnishes data for computing the daily flow of the stream for every day in the year, or for any hour of the day or night.

If a small stream has a flow of 100 second feet, or 750 gallons per second, and a fall of 50 feet it will develop 654 horse-power.

But how is it possible, without a current meter or the services of an engineer, to make a rough estimate of the flow of a stream? First, make soundings across the stream, say, every 10 feet, and from this compute the number of square feet in the cross-section. Then

to find the speed of the current, stake off a straight reach of 100 feet and drop a line of corks in the stream near the right bank. Note the time it takes to float the 100 feet between stakes. Repeat the operation from the opposite bank and again for the middle of the stream. From these three find the average flow of the river per second. Multiply this by the square feet in the cross-section and the result will be an approximation of the volume of the stream in second feet.

Thus, for example a creek 50 feet wide has an average depth of 6 feet the soundings showing 4, 8, 9 and 7 feet of water at the four 10-foot intervals, and of course 0 at either shore thus. Adding these 30 and dividing by 5 we get 6 feet of average depth which, multiplied by the 50 feet of stream width gives 300 square feet for the cross-section. Now the two corks dropped in near the banks each measure 100 seconds in float time the 100 feet, while the center clip floats the distance in 50 seconds. The flow of the stream is thus 1 foot per second—an average for the stream of 1 1/3 feet per second.

This multiplied by the 300 feet cross-section gives a stream flow of 400 second feet. If this creek should be found to have a fall of 40 feet in a certain distance, say, a mile it would be capable of developing 1405 theoretical horse-power at 80 per cent efficiency.

Beautiful waterfalls by no means afford all the power possibilities of rivers. As much power can be extracted

(Continued on page 277)

Every possible railroad bridge is utilized for measuring streams at five- or ten-foot intervals.

Rock Creek, Washington, showing stream bed survey and method of gaging velocity every five feet, by electric current meter.

# Plastic Art of Prehistoric Man

## Clay Figures Modeled by an Artist of Twenty Thousand Years Ago

GRADUALLY our knowledge of our remote art ancestor prehistoric man is increasing. And with our expanding knowledge, so our opinions are changing and again to materially change our point of view. There is a current tendency to credit some of the early inhabitants of our globe with much more advanced faculties than had formerly been supposed. And recent finds seem to indicate that in the physical development, too, our type at least of very ancient man comes much nearer to his modern descendant than was hitherto believed.

Public attention has recently been drawn to a discovery in the cavern at Tuc d'Audoubert, Department of Ariège, France, which throws into the limelight the remarkable work of the prehistoric artist. The carvings, often very clever of prehistoric man have long been known and only recently we had occasion to describe the wonderful mural paintings of Altamira in the Spanish Province. But more remarkable perhaps than any of these are the clay modeled figures of humans discovered by Count Begouen in the cave of Tuc d'Audoubert.

Some time ago the Count had found in the cavern prehistoric, natural paintings of animals. In his further explorations, last October he broke a way through a mass of stalactites, and at the end of a gallery over two thousand feet back from the entrance he came upon clay figures representing a male and a female human in wonderful state of preservation as our illustrations show. The two figures were both against a ledge of rock which has fallen from the vault to the floor of the cavern. The foremost figure, a female, is thirty-two inches long and measures eleven inches across the widest part of its body. The corresponding measurements in the male figure are each about one inch greater. The side of the body lying against the ledge has been left in the rough, unmodeled. While the cavern is fairly dry, and the clay is traversed by numerous cracks, by great good fortune the figures have been left either wholly or almost intact. The only damage is that one horn and the tail of the female are broken off; the latter having been found in the floor of the cave. The surface of the figure has evidently been smoothed by the artist's hand, whose marks can still be distinguished. The eye of the female is made out of a clay ball with the pupil marked by a pit giving it a very lifelike appearance. The male has more or less a round, somewhat lifelike eye. The beard is drawn in with lines evidently with a sharp stick or bone while for the woolly mane the artist used his thumb, whose imprint can still be clearly distinguished.

Around the statues were found imprints of human feet and of bears paws. The discovery indicates to move the figures from their original site, for fear of damage to them.

### Logwood of Commerce

THE imports of logwood into the United States during 1910 amounted to 2,968 tons, valued at \$499,418. The largest amount more than one-half of the total tons came from Hayti, 11,187 from the British West Indies, and 1,035 tons from British Honduras. The remainder is derived from Mexico, Santo Domingo and from the northern part of South America. Logwood was first shipped to England during the reign of Queen Elizabeth but the unskilled divers of her time found that it yielded a fugitive color, and so in the twenty-third year of her reign logwood was prohibited from being used under severe penalties. After a hundred years of prohibition from the English markets it was again allowed to be imported and used. It came into use in the United States during the middle of the eighteenth century, and at one time formed a much more extensive trade than it does at the present time.

The tree which produces logwood (*Campeche wood* or *palo de campeche*) is botanically known as *Hem-*

*teopsis campechensis*. It often reaches fifty feet in height and sometimes from twelve to twenty four inches in diameter. The wood is very hard, of a fine compact grain, a specific gravity greater than water, and is almost indomitable in contact with the soil and air. The pinnate leaves are handsome and of a fine dark glossy green color resembling those of the white birch; the flowers are rose shaped in fine yellow racemes.

The trunk is cut into large logs, the bark and the

taille aride unites with it, forming blue compounds. Gelatine throws down reddish flocculi. Stannous chloride renders it black.

Logwood shavings yield their color to water and alcohol; the latter extracts it more readily than water. The color of its dye is red, inclining to violet or purple. Its aqueous decoction, left to itself, becomes yellowish; and at length black. Added to yellow, it becomes deeper its color and give it a purple hue. The proper shades and colors are obtained by the use of aluminum mordants. A blue color may be obtained from it by the addition of verdigris, but the great consumption of logwood is for blacks, which are obtained by alum and iron bases, and of any requisite degree of intensity. Alcohol extracts most of the active principles of the wood and forms a deep colored tincture.

The cutting, bark, and transport of logwood constitutes an industry in nearly all parts of tropical America. The tree is indigenous to the forests of Tabasco in Mexico, to the lowlands, islands, and banks of rivers and lagoons, and gives employment to thousands. It forms one of the principal articles of export from that State. The Honduras logwood trade has been epidemic of late years, although the dye it yields is superior to that obtained from the wood cut in Jamaica and St. Domingo. The Honduras and Mexican wood sells for about \$200 per ton, and the St. Domingo wood for about \$100 per ton. This is a very different price from that which was paid in the earlier days when it was sometimes sold for \$600 per ton. The Jamaica and St. Domingo wood is used in the dyeing of carpets and other coarse cloths, while the Central American is employed for dyeing all kinds of woolen, cotton, and silk fabrics.

### Teaching Children Safety Principles

THE Brooklyn Rapid Transit Company has entered into an arrangement with the American Museum of Natural History for a six month campaign in the public schools of Brooklyn on the subject of safety in the streets of the borough. The American Museum of Natural History has been working along similar lines in the borough of Manhattan for some time, and has in this matter the hearty co-operation of the Board of Education.

The Brooklyn campaign has been in process of planning for several weeks. As rapidly as the time of the two lecturers who are employed will allow, the system of instruction will be extended from school to school, until the entire borough is covered. It is estimated that in the four months which remain before the closing of the schools for the summer vacation most of the territory can be gone over. But the work will not stop with the summer vacation. It is intended to continue it in the vacation schools during the summer months.

The basis of the campaign is furnished by the daily talks to the school children, followed up by the distribution of pamphlets, which the children are encouraged to take home and discuss with their parents. The talks themselves are illustrated by models which enable the lecturers to point out in a graphic way the correct and incorrect methods of boarding and alighting from street cars, and the handling of live wires and similar dangerous objects which may, through accident, be encountered in the public streets.

**Cleaning Gully Heads.**—Automobilists who act as their own chauffeurs and mechanicians will be glad to hear of a practical process for quickly cleaning the heads of sewers and tunnels, and removing of grime accumulated about the openings of the conduits. This process, as recommended in San Antonio, consists in a preliminary treating (pre-purification) with gasoline, followed by ammonia, and finally with great oil of turpentine. The hands are washed thoroughly with soap and water, and the operator is protected with a suit of heavy, and a mask.

Where Count Begouen, breaking through a mass of stalactites, found the figures.

Prepared by the prehistoric modeler, or modelers, but not used: Worked clay found on the floor of the cave.

These figures are said to be the first prehistoric clay figures discovered. The illustration on the left shows one of the blooms in side view. On the right is seen the splendidly modeled head, in front view.

Possibly made twenty thousand years ago. The clay figures of two blooms found in the cave called Tuc d'Audoubert, France.

while unwooded is chopped off because the dark red heartwood is the only valuable portion. After it has been chipped a little while it turns black, and if it lies in the water it dyes it like ink. Its value is in proportion to the size of the logs, the largest being the choicest kind. It is imported chiefly in short lengths, after which it is chipped or ground, and packed in casks and bags ready for the dyers, hatters and calico printers, who esteem it very much because it affords the most durable deep red and black dyes.

Logwood contains a peculiar coloring principle called hematein ( $C_{12}H_8O_5$ ), which forms an orange red solution with boiling water, becoming yellow as it cools, but recovering its former hue when heated. Alkali converts it first to purple, then to violet, and finally to brown, in which case it seems to be decomposed. Ma-

# A New Type of Water Rheostat

By J. N. Clark

THE ordinary form of water rheostat, having one electrode at the bottom of a wooden barrel, or similar non-conducting container, and the other electrode suspended in such a manner that it can be made to approach the bottom electrode, thus diminishing the distance between them and the resistance of the conducting electrolyte, has many disadvantages. In the first place, it is usually necessary to salt the electrolyte (water) to make it conducting enough for most purposes, and this gives rise to unpleasant products of electrolysis, making the rheostat odorous and dirty and often an unsanitary nuisance. Further, the resistance of this salted electrolyte is constantly changing as the electrodes are dissolved in the hydrochloric acid resulting from the passage of the current, so that a constant switch has to be kept of the adjustment of the upper electrode in case a constant current is wanted. And finally, but not least of all, such a rheostat does not give a constant gradation of current with the degree of immersion of the upper electrode, but gives a curve as that shown for "Common Water Rheostat" in Fig. 8. There is a considerable initial increase of current—the minimum resistance of the electrolyte—and after that, there is no considerable additional in-

crease in resistance until the upper electrode is almost in contact with the lower, when the current value rises rapidly, making fine adjustments with the apparatus very difficult.

To obviate these difficulties and also to secure an even increase of current for equal increments of immersion of the electrode over a long range, the following apparatus has been devised by the writer. It consists in the essence of a container 4 which need not be insulating, the preferred form being a long 6-inch iron pipe, capped at the lower end of two electrodes B, placed side by side and lowered together into the pipe 4 by means of some suitable gear, as for instance the pulleys D and the cord, which may be run to a winch for hand raising and lowering of the electrodes. The two electrodes B are of  $\frac{1}{4}$  inch iron rod (thrust through 3-inch rubber cork, as shown enlarged at Fig. 2, and each of these rods is connected to an opposite side of the line. It will thus be seen that the electrolyte between the rods is that which resists the passage of current, and further, that the amount of current passing is exactly proportional to the surface of the rods in the liquid, which varies with the amount they are lowered into the liquid. This gives the smooth curve shown in Fig. 8, marked "Double Electrode Rheostat." Referring again to Fig. 2, which shows the cork at the lower ends of the rods, it will be noticed that to prevent a short circuit should the rods rest on the bottom of the containing tube, a piece of rubber

tubing has been slipped over each one and tied with a piece of string.

The advantage of this form of rheostat are numerous. In addition to its giving a smooth gradation of resistance without stops, it can be held constant at any point, as on account of the large surface of the electrodes exposed to the liquid sufficient current can be forced through ordinary tap water without salting or acidifying it with the result that the resistance of the electrolyte does not sensibly vary, and there are no unpleasant compounds formed, which ordinarily are an unpleasant feature in such a rheostat. Should it be found however, that the water was not sufficiently conducting for the purpose in hand caustic potash may be added drop by drop until the conductivity is obtained. A caustic solution is preferable to salt in that it will not attack and form unpleasant compounds with the iron.

This form of rheostat will be found very useful in many kinds of experimental work, and it is hoped that it will be of service to many experimenters who like the writer, have long sought a reliable rheostat giving a smooth gradation of resistance over a long range.

## The Effect of Static Electricity on Water

A NOVEL static experiment is illustrated in the accompanying sketch. The writer saw it at a popular science lecture but it can easily be duplicated by the home experimenter.

A thin jet of water is arranged so that it shoots about ten feet up. The stream will be made up of fine drops at the farthest end. If now a hard rubber rod (the kind found in static experiment sets) is rubbed and brought near to the stream, the drops will immediately come together to form larger ones. The rubber rod should be held near the stream, and a few feet from the nozzle. The experiment illustrates how static electricity may account for large rain drops.

The apparatus comprises a rubber tube connecting to a water supply having some pressure a jet which

to coincide with the center of the field. The eye-piece is now assembled and the instrument is ready for use.

This piece of apparatus used in connection with the polariscope attachment described in the SCIENTIFIC AMERICAN of June 26th, 1910, page 524 will give the student of mineralogy or chemistry much satisfaction in the purposes of petrographical research. It will be noted that this form of goniometer in operation does not disturb the optical center of the objective as regards the axis of the microscope. The relative dimensions of small objects which are at the same distance from the center of the field may be estimated by turning the goniometer so that a certain circle radii coincides, first with one edge and then the opposite, and noting the angular magnitude. The dimension to be measured should be perpendicular to the hair which passes through its center. This being the case, the tangent of the angle involved is the measure of the dimension. Since for angles less than fifteen degrees, the tangent varies approximately as the angle

Goniometer for microscopes.

themselves the angles which these small objects subtend are measures of their relative dimensions. Thus used the goniometer becomes a unit of microns.

## A Direct Current Motor from a Telephone Ringer

By Guy Hubbard

A VERY good experimental electric motor which is available and has a speed reducing gear may be easily made from an old magneto telephone ringer. The ringer is a self-excited current dynamo having brushes, which rub on the ends of the armature shaft. This shaft is in two sections and is insulated from the armature by a core. The ends of the armature coil are soldered to these sections.

In order to change the machine into a direct current motor a commutator must be put on. The conditions are different from those in a common motor. The commutator is made from a small spool. The sections are of thin brass and should be each a little less than half the circumference of the spool. Short lengths of wire should be soldered to the ends of these, and after fitting them to the sides of the spool they are fastened with a rubber band snugged around them.

The brush on the gear end of the armature is loosened and turned around. A small hole is punched in it and adjusted so that it is on a line with the center of the armature shaft. There is a tapered hole in this end of the shaft. The commutator is fastened on by a wood-screw which fits the spool and is somewhat longer. The threads are filed from the end of it so that it fits the hole which is put on the end of the shaft with its open space exactly opposite the centers of the channels of the armature. The wire from one of the sections is bent over the end of the spool and is twisted around the head of the screw. The commutator is then fastened by a few turns of a hairpin.

The brushes are narrow strips of thin brass fastened to small wooden blocks. Each of them should be fitted with a binding screw. These are fastened on each side of the commutator and adjusted to rub on the commutator or on points exactly opposite. The wire from the other section is bent around the end of the spool and placed in the hole in the contact spring, so as to run smoothly when the armature is turned. The contact spring which rubs on the shaft and the one with the hole in it are connected by a wire. The machine will now run at top speed when a strong battery is connected to the brushes. The armature will have to be started unless in a certain position, as it is a two-pole machine.

Motor constructed out of a telephone ringer.

current of current until the upper electrode is almost in contact with the lower, when the current value rises rapidly, making fine adjustments with the apparatus very difficult.

To obviate these difficulties and also to secure an even increase of current for equal increments of immersion of the electrode over a long range, the following apparatus has been devised by the writer. It consists in the essence of a container 4 which need not be insulating, the preferred form being a long 6-inch iron pipe, capped at the lower end of two electrodes B, placed side by side and lowered together into the pipe 4 by means of some suitable gear, as for instance the pulleys D and the cord, which may be run to a winch for hand raising and lowering of the electrodes. The two electrodes B are of  $\frac{1}{4}$  inch iron rod (thrust through 3-inch rubber cork, as shown enlarged at Fig. 2, and each of these rods is connected to an opposite side of the line. It will thus be seen that the electrolyte between the rods is that which resists the passage of current, and further, that the amount of current passing is exactly proportional to the surface of the rods in the liquid, which varies with the amount they are lowered into the liquid. This gives the smooth curve shown in Fig. 8, marked "Double Electrode Rheostat." Referring again to Fig. 2, which shows the cork at the lower ends of the rods, it will be noticed that to prevent a short circuit should the rods rest on the bottom of the containing tube, a piece of rubber

Graph of the common and improved rheostats.

may be made from glass tubing and which should have a small opening so that the stream of water will be fine, and a rod which may be charged.

At first, the use of a glass rod or a stream of oil is suggested. On a smaller scale the effect of the charged rod on a thin stream of water from an ordinary faucet may also be tried.

## Goniometer for Microscopes

By C. C. Kiplinger, Instructor of Science, Lincoln (Ill.) High School

THE manufacturers of microscopes rarely list low priced instruments with rotating scales. Hence the possessor of one of these otherwise efficient instruments is ordinarily unable to measure crystal and extinction angles.

The goniometer here described is simple in construction and efficient in action. A ring, or flange, of cork one quarter inch square in cross-section should be cut of such internal diameter as to fit the eye-piece fitting. This ring should be blackened with a mixture of lamp-black and vasoline oil. When dry, it is slipped over the eye-piece and brought to the position shown at A in the drawing.

Another cork ring C cut so as to have a cross-section one quarter by one half inch, and tightly fitting the draw tube, is placed on it at C. This flange forms the support for a scale graduated in degrees. The scale is best made as follows: A large circle at least a foot in diameter, is drawn on white card board and the degrees marked as accurately as possible. This scale is then reduced by photography to the required size, and a print is made on a "gas light" poster. The print should be cut so as to fit the draw tube, and fastened to its cork support with a little shellac varnish, as indicated at R. A short piece of a pin or needle is pressed into the cork ring at A to serve as a pointer.

The eye-piece must be fitted with cross hairs. A bit of silk thread is frayed out and several individual fibers obtained. The lenses having been removed, a bit of machine oil is put on the glass plate at two diametrically opposite points. One of the fibers is stretched across the field at these points, using a splitter of wood to assist in the operation. Another fiber is fixed at right angles to the first, and their intersection made

## The Marino System of Color Telephotography

IN a recent number of *Lumière Eclair*, M. Marino explains his system of telephotography in black and white and in colors. Selenium is of course used, as in most telephotographic systems. It will be recalled that in the Kora process, the transmitting element is a selenium cell, selenium being a metal the electrical resistance of which is a function of the luminous intensity to which it is subjected at any given moment. Marino employs not one cell, but a battery of seven cells, each responsive to a single color—red, orange, yellow, green, etc. In transmitting tint pictures in black and white each cell responds to the particular radiation to which it is sensitive. In transmitting pictures in colors they transmit the fundamental hues of the original, decompose them at the transmitting station, and recombine them at the receiving station.

At the transmitting station the photographic plate *P* of the colored picture on which is to be transmitted in black and white, is illuminated by an electric arc *E*. Each ray of light after passing through the plate falls upon a convex lens *L*, by which it is refracted to the concave lens *L'*, where in turn it is thrown on a prism. The prism analyzes the ray into its fundamental spectrum colors and the various colored rays in turn fall upon the corresponding selenium cells *A*, *B*, *C*, *D*, *E*, *F*, *G*. The cells are so mounted that rays of a particular color will always fall upon the proper cell. The cells are included in the circuit leading to the receiving station. Their total conductivity is equal to that of a single cell receiving compound light. The effect produced at the receiving station, because of the variable conductivity of the entire battery of transmitting cells is proportional to the amount of light received from any point of the original image at a given moment.

The original photograph is decomposed point by point by regularly displacing across the photographic plate an opaque ribbon perforated with very fine holes, arranged in step-like series so that the upper edge of the second line at the level of the lower edge of the first, etc. as shown. Each perforation as it passes across the plate permits the passage of a horizontal band of light from the hole behind the plate. The horizontal distance between two consecutive holes or perforations is such that one perforation at a time passes across the plate, and that an appreciable interval is allowed between the exposure of the plate by the two ribbons. During this interval the selenium cells are at rest and are thus enabled to lose their residual conductivity, which they tend to preserve as the result of a well-known effect of inertia or hysteresis. Because the intensity of the light is distributed among all the selenium cells, each receives but a part of the light resolved by the prism, the hysteresis is considerably diminished.

At the receiving station a short length of wire *W* is to be found, to which a very weak direct current is supplied. The arc is connected with the line circuit and once with the selenium cells. The variation in resistance of this circuit have a very marked effect on the luminous intensity of the arc, although that effect is not noticeable to the eye. These variations in light fall on a photographic plate *P'*, in front of which an opaque ribbon pierced with holes or openings identical with those of the transmitting ribbon is displaced synchronously with that of the transmitting station. The sensitive plate is affected in such a manner as to reproduce the original together with all the gradations in color and tone.

The Marino system of telegraphing pictures in colors.

It is of course practicable to transmit not only a colored photographic transparent, but also the image of any fixed object reflected by a mirror. The perforated ribbon passes over the reduction exactly as in the case of the telephotographic plate.

In transmitting photographs in colors the seven cells of selenium instead of being mounted in parallel on a common circuit, are divided into three groups, each of which form part of a circuit of a Poulsen arc, generating waves of varying length. At the receiving station three

wave detectors included in three resonant circuits (each of which has a frequency corresponding with that of one of the sets of waves emitted by one of the Poulsen arcs) influence three resonant areas, in front of which colored filters are mounted corresponding with the three groups of selenium cells. The three sets of colored rays emanating from the three arcs are concentrated by lenses on a sensitive autochrome plate, explored in the manner already explained, by an opaque perforated ribbon, so that each point is allowed to exert its influence, while at the same time the corresponding point of the original is illuminated by an opening in the perforated ribbon of the transmitter.

By superposing the impressions made by three sets of colored rays, the shades and intensities of the original are exactly reproduced in their proportionate intensities. When the original has been completely explored by the perforated ribbon the receiving plate has completely responded. Developing is the next step.

## The Lundin Decked Lifeboat

IT is now almost a year since the urgent necessity for realising an equivalent referring to life-saving appliances at sea was brought home with terrible force to the public mind through the sinking of the "Titanic." Since that cruelly unnecessary loss of life, in England and abroad, there have been active in devising boat construction which would meet all the new requirements made by the Board of Supervising Inspectors and make it possible to carry three times as many boats as formerly constituted the equipment of an ocean liner, without encroaching unduly on the deck promenade space.

Before the general adoption of wireless stations on ships, those who were forced to betake themselves to the boats in case of disaster, might expect to sail about for days before reaching land or being picked up but now, with many more ships plying back and forth in the prescribed lines of convenient navigation help can reasonably be expected to arrive within a few hours, and it is, therefore, merely a question of having means to keep every body afloat under fairly comfortable and safe conditions until the rescuing vessel appears on the scene. If this means of keeping afloat can also be propelled and maneuvered as readily as the standard type of life-boat it is of course an added advantage, and if it is practically impossible to overturn it or dent and damage it by smashing against the side of the ship, we may say. The Lundin life-boat is found.

The Lundin decked life-boat seems to answer to this description perfectly, as was demonstrated recently in exhaustive tests made at Newport News and San Francisco by the United States Army Transport Service, and only a few weeks ago by the Board of Steamship Inspectors, when they visited New York for the purpose of looking into the merits of various marine life-saving appliances.

The boat consists of a decked hull with the sides extending above the deck some 18 inches. Folding weather boards of a substantial construction are hinged to the top edge of the sides and may be raised in a second, automatically locking themselves in the upright position. Similar boards are then raised at the ends, and the boat is ready for lowering.

The boat is divided into eight watertight compartments by transverse bulkheads, which carry the deck above the load waterline, thereby making the boat self-bailing by means of scuppers through the bottom in each compartment. A scuppers hole is also provided in each compartment to allow the scuppers and pump-

How the Lundin lifeboat is constructed.

Detachable fenders prevent staving of the hull.

Lundin boat undergoing a Government test.

On each side a large tandem is balanced of a very buoyant material (Balsa wood), which is so treated that the buoyancy is permanent.

These boats carry the regular control going equipment, including rudder, sail, and rigging, and can be rowed or sailed as readily as the ordinary type of life boat. Furthermore, they are well adapted to being towed, which is a feature of some importance, since it is the intention to carry some motor-equipped life boats on large passenger carriers.

This lifeboat is rated with a co-efficiency of 0.6 as compared with a co-efficiency of 0.6 for ordinary life boats, and has 25 per cent more carrying capacity for a given length.

Two of these boats may be stowed on each other, or towed, without risk of damage under one pair of davits, and it is easy to compute what a saving in deck space this represents.

## The Decision in the Wright Aeroplane Patent Case

ON February 27th, 1913, Judge Hessel, in the District Court of the United States for the Western District of New York, handed down a decision upholding the Wright patent in the case of the Wright company v. Herring-Curtiss (company and Green H. Curtiss). All the elements in the Wright machine were found to be old, but the question was whether the Wright was the first to discover that the vertical rudder of a flying machine must be used in conjunction with wing warping devices or ailerons in order to prevent the machine from spinning to a vertical axis? The Court held that they were, and that Curtiss had infringed the patent in which that discovery is described and claimed. The decision is a blow for republicanism in its entirety, but the following abstract will give the average reader all that he can know.

There are eighteen claims in the Wright patent, but only claims 1, 3, 4 and 5 were held to be infringed. They read as follows:

3. In a flying machine, a normally stationary having lateral movement, capable of movement to different positions above or below the normal plane of the body of the aeroplane, such movement being in a line transverse to the line of flight where by said lateral movement is caused to move to different angles relatively to the normal plane of the body of the aeroplane and to different angles relatively to each other, so as to present to the atmosphere different angles of incidence, and means for simultaneously imparting such movement to said lateral marginal portions, substantially as described.

7. In the flying machine, the combination with an aeroplane, and means for simultaneously moving the lateral portions thereof into different angular relations to the normal plane of the body of the aeroplane and to each other, so as to present to the atmosphere different angles of incidence of a vertical rudder, and means whereby said rudder is caused to present to the wind said angle of incidence, the side of the aeroplane having the smaller angle of incidence and the other side being at an angle to the atmosphere, substantially as described.

14. A flying machine comprising spaced curved aeroplane, means for moving the opposite lateral portions of said aeroplane to different angles to the normal plane thereof, a vertical rudder means for moving said vertical rudder toward that side of the machine presenting the smaller angle of incidence, and a horizontal rudder, operable with means for preventing its upper or under surface from the resistance of the atmosphere, substantially as described.

15. A flying machine comprising spaced curved aeroplane, means for moving the opposite lateral portions of said aeroplane to different angles to the normal plane thereof, a vertical rudder means for moving said vertical rudder toward that side of the machine presenting the smaller angle of incidence, the lower resistance to the atmosphere, and a horizontal rudder provided with means for preventing its upper or under surface from the resistance of the atmosphere, said rudder being located at the rear of the machine and said horizontal rudder at the front of the machine, substantially as described.

It was contended for the defendant that the Wrights merely improved the known gliding machine, and that the wing tip horizontal rudder and vertical rudder were old separately and in combination.

But the Court could find no similarity between the constructions of Lilienthal, Piller and Chanute on the one hand and the Wrights on the other.

Curtiss analyzed the prior patents cited as antecedent art against the Wrights, but failed to find that they revealed the Wright principle.

The Henson British patent of 1862, the Adams American patent of 1880, the Lanchester British patent, the patents to Cresset and Johnson the Herte British patent of 1870, the famous Mouillard patent (No. 565,797), and the Rouillon British patent of 1868 were all rejected as containing no indications of the Wright invention. None of these patents had in mind the principle that the steering or control of the machine depended upon the tilt of the wings in connection with the use of the vertical rudder.

Importance was attached to the revived Maitland application for a patent, dated January 4th, 1909, but the Court thought there was "an after failure to find that the catamaran like structure of 180 feet over all and revolving disk 40 feet in diameter, with its decks, compartments and machinery, which was not that it was even recently proposed to reduce it to practice and without such showing it is devoid of material significance." Even assuming that it belongs to the prior art, the machine is not provided with movable side ailerons simultaneously adjustable, or a movable rudder, but has a fixed rudder which has no connection with the ailerons.

One additional publication, the Ader article, published in France in 1888, was dwelt upon. Ader's apparatus somewhat resembles the wings of birds, but it is not clear whether it could be moved forward and backward. As our readers know, the machine was of the monoplane type and carried a motor "but" said the Court, "the machine was not connected between the winging surfaces and the rudder by which the lateral balance of the machine was secured, the publication is not entitled to be considered in this connection, as it fails to embody such elements."

Continuing, the Court states: "A summary of what had gone before in aerial machinery, unimpeachable disclosure first, publications which did not contain descriptions of apparatus of such clearness and definiteness as to enable the skilled in the art to construct therefrom an operative device, or clearly suggesting ways or means to solve the problem of lateral balance."

I am, of opinion, after complete consideration of the testimony on both sides, that the patent given by their method of securing the equilibrium of the planes made an important advance in an embryonic art. They were not the first to conceive the idea of using monoplane or biplane surfaces for surfaces of resistance of the atmosphere at two planes at their margins one above the other, or to use vertical tails or rudders for steering, or to place horizontal rudders at the rear of the machine, or to use upward or downward in its flight. The prior separate use of such elements is freely admitted by the patentees, but they cannot, rightly, I think, that the patented combination was a new combination. They forming a new and novel result. The antecedent patents, the efforts to perfect the gliding machine and to provide means for restoring equilibrium, in short, the unsuccessful attempts to remedy or better imperfections in aerial machinery, all bear witness to the fact that the achievement of the patentees required the solution of the invention. Having attained success where others failed, they may rightly be considered pioneers in ventors in the aeroplane art. Their concept was practical, and their combination of old and new elements actually advanced the operativeness of aeroplane of this type from which astounding flights have resulted."

There was much discussion at the bar as to claim 5, which does not include the vertical rudder as an element. The im-

portant feature of the claim is that the lateral marginal portions of the plane must be capable of movement to different angles relatively to the normal plane of the aeroplane and about an axis transverse to the line of flight, the purpose of said movements being to present to the atmosphere different angles of incidence. It was argued that without the co-operation of the vertical rudder the claim was void. The Wrights contended that there is shown a sub-combination which is valid and which should be sustained. There is evidence that the marginal end of the supporting planes are capable of movement to different angular relations to the plane and to each other without the assistance of the vertical rudder, but the result was not satisfactory, as the machine in its flights added to the side, an imperfection which has been remedied by the use of the vertical rudder in connection with the ailerons. So the Court held that it is not essential to the validity of claim 5 that all parts of the machine or all parts specified in other claims, which are necessary to its operativeness should be included therein. The Court must be left to the specification for a disclosure of its parts necessary to insure the practical utility of a patented device. In the Wright structure a new and novel result was attained simply by having the ailerons at the ends of the planes without the supplemental feature of the vertical rudder. The winging feature is, in fact, the essential part of the machine while the vertical rudder insuring successful flying is a valuable adjunct without which lateral balance could not be restored. The employment, in a changed form, of the winging feature by another inventor, or, though better effects or results are obtained, does not avoid infringement.

In there is a "curtiss machine" tendency to spin or reverse which is checked or corrected by the operation of the vertical rudder?

The Court answered thus: "If I am correct in my interpretation of claim 3, a lay applicant, without knowledge of the art, the ailerons of defendant's construction and the manner of using them are within its scope. The witness, Curtiss, frankly testified that the purpose thereof is to preserve the lateral balance without the use of any other element or part. It making no difference whether the aeroplane is in a straight or curved flight such evidence supports the infringement of the claim under consideration."

The defendants are believed to have appropriated the substance of claim 7, and to have infringed claim 11, inasmuch as in addition to the essential elements of the Wright patent and the object with which such elements are used, they also employ in their aeroplane a horizontal rudder for presenting its upper and under surfaces to the atmosphere at different angles. Claim 15 contains the essential elements and specifies that location of a vertical rudder at the rear of the machine and a horizontal rudder at the front thereof.

"The defendants have embodied in their aeroplane the various elements of the claims in suit. While it is true, as pointed out by the defendants, that they have constructed their machine somewhat differently from complainant's and do not at all times and on all occasions operate the same on the Wright principle, yet the changes they have made in their construction relate to the form only. They have constructed their machine so that it is capable of restoring equilibrium in substantially the same manner as complainant's machine, and the evidence is that on occasions, depending upon aerial conditions or other disturbing causes, they use the vertical rudder not only to steer their machine, but to assist the ailerons in restoring balance."

The decision marks the first important victory for the Wrights in this country in their effort to uphold their patent. Both George and Orville Wright have handed down similar decisions.

## Notes for Inventors

**A Combined Snow Plow and Shovel.**—In patent No. 1,048,812 Frank Darling of Plano, Ill. prevents a combined snow plow and shovel, which has blades so connected with each other and with a handle that they may be shifted to form either a snow plow or shovel.

**Collapsible Drinking Cup.**—Henry W. Bowman of Harboursville Ky. has patented No. 1,040,109, a collapsible drinking cup in which a strip of material is bent to form a spiral spring along the wall of the cup and has a handle with a co-operation in holding the cup collapsed when not in use.

**A Matchbox Lantern Globe.**—Patent No. 1,048,981, to George A. Marchetti of Pittsburgh, Pa., has for its object a lantern globe of glass upon the edge of which a protective metal sheath is formed by a projecting metal upon the edge of sufficient thickness to protect the edge from chipping.

Another Spring Wound for Antennae.—Harper E. Strickland of Englewood, D. C. in patent No. 1,040,418, presents a vehicle wheel in which spring bow-shaped spokes extend in pairs between the hub and the rim, the spokes being curved inward toward the inner ends of the spokes and seated in recesses in the hub.

**A Number of Gas-burner Patents.**—Edwin O. Vanzandt of St. Louis assignor to the Gas-burner Manufacturing Company of the same place, has secured patents No. 1,045,564 and 1,044,465 for gas burners a patent No. 1,045,464, for a gas grate and patent No. 1,045,470 for a gas burner including for gas burners various improvements.

**Help for Swimmers.**—A swimming glove is shown in patent No. 1,049,438, to Hoy P. Chase of Boston (Cal) and includes in its construction a series of finger and hand and finger portions, a wrist strap which is secured to the tips of the gloving fingers and extends over the back of the glove and is stretched at a point near the wrist so that the hand and fingers are between the web and the back of the glove.

**Match Splints From Pulp.**—Co-operative Rylands of New York city as assignee of Wm. B. Hutchinson of Newark N. J., has secured a patent No. 1,049,477, in which pulp, which is formed from pulp, the pulp being parted into separate strips or splints and a series of grooved rollers being used to shape the splints, the splints being joined together leaving the rollers being cut off into suitable individual splint lengths.

**A Motor-controlling Mechanism.**—Charles H. Pratt of Union N. J. in patent No. 1,049,560 provides a motor-controlling mechanism in which there are a number of motors with means which maintain a predetermined relative speed of the motors, and means for controlling the means of operation by differential gearing between the motors for applying the brake the mechanism for operating the brake being driven by a variation in the relative speed of the motors.

**Assessing Fruit by Weight.** In patent No. 1,049,936, John B. Hart of Austin, Colo., presents a machine for grading fruit in which there is a series of scales for assessing fruit, and means for weighing the fruit are provided for confining the fruit to the scales so that in the operation of the scales the heaviest specimens of fruit will be dropped first and the lighter specimens will be dropped last, thus securing a grading of the fruit by the weight of the respective specimens.

**Notes to Berlin.**—Mr. Emil P. Berline of Philadelphia has been making use of many important inventions beginning with his telephone improvements and extending through the graphophone and numerous others. He has made many famous inventions and his life has been devoted much time and energy to philanthropic work, has received the Franklin Institute gold medal for his services to the world. He has been nominated, the medal being one of six given annually. Mr. Berline had already received, by the recommendation of the Franklin Institute, the Scott medal in honor from the city of Philadelphia.

# Travel In Comfort

When you travel, be comfortable

The tracks and trains of the **Pennsylvania Railroad** are built for comfort

The roadbed is rock-ballasted and evenly graded, and the rails are solid steel. The cars, both Pullmans and coaches, are all-steel, heavy and easy riding. The through express trains have parlor smoking or club cars with moveable easy chairs, and a la carte dining service that is unequalled. All sleeping cars are the latest word in appointments, the coaches are cheerful, commodious and restful.

Limited trains, like the **Broadway Limited** between New York and Chicago, the **24-Hour St. Louis**, the **Pennsylvania Limited**, **Congressional Limited**, and **Chicago Limited** have Pullman observation cars on the rear with moveable armchairs and large windows, as well as an open platform, for viewing the passing scenery. Up-to-date libraries, current periodicals, daily papers, and courteous attendants are features of the Limited train service.

**Pennsylvania Railroad** service enjoys the reputation of being distinctively high grade and comfortable.

## Soldering and Brazing

For nearly all metals, including such difficult ones as copper and aluminum, have been the subject of hundreds of paragraphs in the *Scientific American Supplement*.

We quote a few of the more important articles, as follows:

1757 Full Instructions for Moulding and Welding Cast Iron, give full welding tables and flow security.

1712 Brazing Cast Iron and Other Metals, give detailed instructions for the whole operation.

1800 Aluminum Soldering gives special hints as to when aluminum was about a new thing in the art.

1804 Soldering and Brazing, presents some brand new information, and contains a complete manual for practicing soldering and brazing.

1807—Some Soldering Appliances, describes the latest types of soldering.

1811—Soldering of Metals and Preparation of Solder, gives some hints for all the soldering.

1810 1822, 1823 contain a table of dry gravity as a guide for the fast reduction of all the soldering.

Each number of the Supplement costs 10 cents. A set of papers containing all the articles here mentioned will be mailed for 50c.

Send for a copy of the 1919 Supplement Catalogue, free for any address.

## Gasoline and Its Substitutes

A Great Problem and Its Solution

THE price of automobiles is going down but the price of gasoline is going up. The wholesale price in New York is now 17 cents a gallon. A year ago it was 9 and 10 cents, but rose to 16 cents by July, 1912. The relation of kerosene to gasoline has been strikingly reversed. In former years there was so little demand for gasoline that it was an almost valueless by-product in the mineral-oil industry, and therefore as much as possible was left in the kerosene. This, however, increased the unsatisfactoriness of the latter and the consequent danger of its use. States passed laws to safeguard the lives and property of their citizens by preventing the flash point and burning point of kerosene, and it was the duty of the State-oil inspectors to see that the kerosene offered for sale came up to the required standard.

At the present time gasoline is worth about twice as much as kerosene and now it is gasoline that is adulterated with kerosene.

The United States is fortunate in having great oil fields within its borders, being rivaled only by Russia in this respect. In other countries the situation is less acute. Gasoline in Germany sells for 40 cents a gallon. The International Association of Requiring Automobile Clubs has offered a prize of \$100,000 for a fuel which may be used as a substitute for gasoline, and a British Society one of \$10,000. Relief may be found in any one of three ways:

1 By increasing the gasoline supply  
2 By devising apparatus—carburetors—capable of utilizing other fuels such as kerosene, naphthalene, crude oil, vegetable oil, alcohol, etc.

3 By compounding or discovering a new fuel which can be used in the engine just as gasoline is now used, without any substantial modification of the engine or its carburetor. It is toward the solution of the last stated problem that the price above mentioned has been offered.

For a better understanding of the gasoline question it may be briefly stated that crude petroleum, by a process of fractional distillation, may be separated into a multitude of component oils differing from each other in several gradations. The aim is to produce the maximum yield of three principal products for which there is the greatest demand, these being kerosene of 43 to 47 degrees gravity, naphtha of about 42 degrees gravity, and automobile naphtha, or as it is now more commonly called, gasoline of about 58 degrees gravity. Kerosene, naphtha and gasoline constitute about 60, 4 and 10 per cent respectively of the crude petroleum. However, due to the unsettled state of the nomenclature of the mineral oils, these products sometimes go under modified names, particularly the "gasoline," which are to-day extensively sold under gradities considerably less than has been customary some years past. However these products may be named, the fact remains that they are ordinarily found in commerce, are really unseparated mixtures of higher and lower gravity oils, their components being so proportioned that the average gravity corresponds to the gravity of kerosene, gasoline, and the like.

Leaving out of consideration the opening up of new oil fields, other sources of gasoline have been searched for. An interesting source of gasoline and process of recovering it is as follows:

As well known, natural gas is found in enormous quantities in some of the oil regions. Now this natural gas contains a small quantity of naphtha vapors. Naphtha may be defined as including all hydrocarbons, and each of them, which are liquid at ordinary temperatures and atmospheric pressure, and which have lower boiling points than the normal hydrocarbons of burning oil (kerosene). The natural gas may be said to be carbureted with naphtha. Within this quantity of naphtha, as stated, is small, and the amount varies in the gas from different oil wells, yet in the aggregate a large quantity of naphtha is daily treated on large plants

with the other constituents of natural gas. In order to recover this naphtha the gas is first cooled and then passed through an absorbing tower where it comes in intimate contact with descending streams of a "menstruum." For the latter the following substances may be used, hydrocarbons whose boiling point is separated by a considerable temperature difference from that of the gas. These are naphtha, fatty oil, amyl alcohol and others. The naphtha thus absorbed is separated from the menstruum by fractional distillation. If the absorbed naphtha is to be separated otherwise than by distillation from the menstruum enriched thereby, a menstruum must be used capable of such separation. Such are ethyl alcohol sufficiently hydrophilic in nature, mixtures of acetone and methyl alcohol. These absorb naphtha and on dilution with water part with it. Therefore it is only necessary to add water to the menstruum saturated with naphtha, whereupon the naphtha will separate out as a supernatant layer which is decanted off.

Another method of producing gasoline is by converting kerosene into gasoline. The oils, it should be recalled, are hydrocarbons belonging to the paraffine series corresponding to the formula  $C_nH_{2n+2}$ . Kerosene is composed of a mixture of the higher members of the series, gasoline of the lower. Now if a reaction like the following  $(C_{12}H_{26} + CH_4 + C_2H_4 + C_3H_8)$  could be effected, which means that one molecule of a higher member is broken up into two molecules of lower members, splitting of some carbon as residue, the problem would be solved, provided the process could be carried out economically. Now this very process, called "cracking," is carried out in breaking down the members above the kerosene members, by superheating them in the distillation process. The yield of kerosene is thereby increased, unfortunately the breaking down of the lower members of the series into still lower ones appears to offer greater difficulties. However, a patent has recently been granted for a process of converting kerosene into naphtha or gasoline by subjecting the kerosene to the powerful influence of properly applied decomposing temperatures, ranging from a white cherry red to a full white heat. The heat is applied by means of a submerged electric heater. An electrode of heat-enduring material, submerged near the surface of the oil, maintains an incandescent temperature by a low-voltage, high-ampere electric current. The vapors evolved are withdrawn and condensed. The condensed distillate contains a mixture of light oils and heavier still, unconverted oils. They may be separated by fractional distillation, or the mixture may be subjected to successive distillations, the heavier oils being the process of "cracking" the heavier oils releases them of more or less carbon, which is deposited on the hot electrodes and partly goes into suspension and gravitating toward the bottom of the condenser.

The use of kerosene, crude oil, even vegetable oils as a substitute for gasoline, offers comparatively little difficulty in engines that operate on the hit or miss principle, that is where a uniform charge of air and oil is drawn into the explosion chamber of the engine. But in the automobile engine, where the charge is controlled by the throttle valve, the great difficulty arises made on the carburetor to furnish the most desirable mixture of oil vapor and air for varying conditions of speed and load. The problem of devising a well regulated carburetor is greatly complicated when it is proposed to use kerosene, crude oil, paraffine, naphthalene, etc. The latter two are sold at ordinary temperatures and must therefore be heated. Throat carburetors designed to use such fuels have been patented, but whether they will operate so successfully as their inventors claim, remains to be seen. It is well known that kerosene may be used after having been stored and warmed up the engine with gasoline. It will be found, however, that kerosene will not operate as well as gasoline, and that it will not operate as well as gasoline.

### From Nature's Laboratory

Nature has given us water—her one great solvent—and she has given us FLAKE GRAPHITE—her one great aid to better lubrication. The tiny oily FLAKES cling tightly to the bearing, making a veneer-like coating of marvelous smoothness and endurance.

### DIXON'S Graphite Greases

Have received most remarkable endorsements from the Speed Kings of Motordoms.

DIXON'S GRAPHITE GREASE NO. 877 makes better lubrication than any and lasts longer.

One ounce and a half of our No. 877 grease will lubricate one 100-horsepower motor for 100 hours. See page 100.

For more information, write to: DIXON'S GRAPHITE GREASE CO., 1100 Broadway, New York, N. Y.

### MAXIM SILENCER BOOK FREE

The "new" Maxim Silencer, the latest and most complete of its kind, is now being sold in the United States. It is the only one that will silence any rifle, and it is the only one that will not get hot. It is the only one that will not get hot. It is the only one that will not get hot.

Write for the Catalogue and Book Free. It will tell you all about the Maxim Silencer, and it will tell you all about the Maxim Silencer.

### A New Novel

By **SIR GILBERT PARKER**

### The Judgment House

It is a story of international interest—its sympathies as wide as the world. The destinies of nations are interwoven with the lives of the two heroes—one a millionaire, a pioneer of the Cecil Rhodes type, the other a diplomat, with finger on the pulse of the world. And the woman, like Cleopatra, influences the careers of empire-builders by her beauty and her cleverness.

All those qualities of devouring interest which charmed a million men and women in "The Right of Way" and "The Weavers," are even more fully disclosed in the new work of the Master's hand.

described in scientific articles contained in Scientific American Supplements 1403, 1405, 1466, 1510, 1511. Price 10 cents each. For sale by Messrs. C. & Co., Inc., and all newsdealers.

**Mobile Portable Parlor Lamp**

The new and most beautiful lamp, with a mobile and portable design. It is the only one that will not get hot. It is the only one that will not get hot.

Write for the Catalogue and Book Free. It will tell you all about the mobile portable parlor lamp, and it will tell you all about the mobile portable parlor lamp.

**NATIONAL STAMPING & ELECTRIC WORKS**  
412 S. Clinton Street, Chicago

Where storage of water for power purposes is effected, it is evident that the greater the fall the more valuable is the reservoir. A reservoir containing 2,562,000 cubic feet of water, or a little more than 3½ acres 16 feet deep, if it had no fall or series of falls of 3,640 feet will produce 10,000 horse-power the year through. On the other hand, if the fall is but 16.4 feet, the reservoir to produce 10,000 horse-power will need to hold 264,200,000 cubic feet of water, or in over 300 acres 10 feet deep, or 35 acres 100 deep.

Water is the country's greatest resource. Coal, oil and other power producers are exhausted, but the use of water, never. No long as rain and snow fall moisture is evaporated and clouds formed and their particles precipitated again, so long the endless chain will revolve and streams can be employed for power, irrigation and navigation in their travels from mountain heights to ocean level over and over, again and again. But we should know our rivers more thoroughly, and eventually we should control and utilize them with almost the certainty that it is attained in the handling of a city water supply. Where the Government has done one saving station, it should have a dozen.

### The Chemistry of a Soldering Flux

THIS action of a flux during the operation of soldering consists, briefly, in cleaning the surfaces to be soldered, keeping them clean, and letting the solder make contact with them.

The impurities generally occurring on metallic surfaces are grease or other organic matter and oxides. An effective flux must have the power of dissolving all these and flooding them out of the way.

Zinc chloride is the flux most commonly used. It fuses upon the surface at a low temperature, and dissolves organic matter with great readiness. It removes oxides by converting them to chlorides of less melting points, which flow out of the way either alone or in solution with the fused zinc chloride. The chloride of iron even dissolves to a considerable extent. Zinc chloride is usually applied in water solution. But its flowing power and its cleaning action are increased when it is used in solution in some alcohol, fatty acid, or oil such as oleic acid or castor oil. With all these solvents it combines in large proportion to form thick, syrupy liquids with high boiling points. The cleaning action is improved by the solvent, which dissolves metallic oxides and chlorides.

Ammonium chloride in solution in glycerine is frequently used as a flux, and is especially suitable where a very clean job of soldering is necessary, since these materials are driven off by heat and leave very little residue. The action upon organic impurities is not so strong as that of zinc chloride, but the glycerine flows very readily, and readily dissolves the chlorides formed by decomposition of the ammonium chloride, so that this mixture is a very effective flux.

If the organic flux, resin is perhaps the one most commonly used. It is most effective for soldering tin and lead surfaces. It owes its efficacy in cleaning to its ability to form soluble resins with tin and lead oxides. Similarly, various oils and fatty acids, such as palm and castor oils, oleic and stearic acids, have value as cleaning agents and make good fluxes.

The physical properties of a material also determine its usefulness as a flux. Its viscosity should be light enough at the melting temperature of the solder to permit of a free flow on the surface. Its surface tension in contact with the heated surfaces and molten solder should be quite high. This is a vital characteristic. That is, these surfaces should not be easily "wetted" by the flux. The importance of this may be seen by comparing the flowing power of a petroleum oil with that of rosin. It will be seen that the mineral oil wets a globe of molten solder completely, while the rosin shows a negative tendency. The oil forms a film which separates the solder from even a clean metal surface, while the rosin film breaks, lets the solder touch the metal, and even flows the two together.

## Valuable Books

### Scientific American Reference Book

EDITION OF 1913

This drawing shows the general method by which the four-track tunnel of the new Lexington Avenue subway of New York will be constructed beneath the Harlem River.

TRENCH-AND-TUBE METHOD OF CONSTRUCTING SUBAQUEOUS TUNNELS.—[See page 286.]

FOR many years the public has seen in life insurance merely a means for providing against the hardships which may come to the individual and his family in the event of his untimely death. Now, however, the public is beginning to realize, looking at the matter from their own standpoint, have used mortality tables and vital statistics as a means of gauging the health of their cities and nations, and have reached to a given point in the life of the individual. The public has seen, even with this restricted horizon, that the life insurance companies have derived great advantage from the existing system. But the world moves forward. To-day the companies are beginning to realize that the public has a right to know the value of the valuable services, benefiting the public and themselves alike, for in this the interests of both run clearly parallel that both gain by the prosecution of human life insurance. The public has seen that the insurance companies have been the cause of the Equitable Life Assurance Society, discusses in our current SUPPLEMENT the alarming increase observed in middle age mortality in American communities. The public has seen that the common, hardly novel, phrase of the middle-aged group, "I value my life," is the basis of the community. What may be the cause of this increased mortality? The operator is ready with the reply that the increase is merely apparent, or at least that it is not as serious as it seems. He points to the beneficial effects more than outweigh the observed losses. For, it may be argued, if we protect our infants from the attack of the diseases, which until a few years ago were the cause of the high infant mortality, we have a comparatively few strong individuals (for most of these would have survived even under the old order of things), but a greater proportion of weaklings, who are liable to attack at a later date, and who are more likely to die at a later date, which has been weakened out. The result will be that our older "population" will be a less highly resistant stock, which therefore exhibits a higher death rate. While there may be some justification for this view, unfortunately evidence is altogether against it. The public has seen that the insurance companies place the great improvement in the conditions of infant mortality is a matter of comparatively recent growth, so that its effect upon our middle-aged population can be gauged by the statistics of the last few years. In comparison with English statistics, which shows that there is increase observed has been at most very slight, while in this country the increase in middle-aged mortality, which is the age group that has been attacked at no less than 20 per cent. The increase cannot be ascribed, then, for as the more result of the better preservation of human life in infancy, but must be ascribed, it seems, to the increased struggle of modern life, and to other

## Engineering

**Asphalted Highway.**—The State of Washington will spend \$9,000,000 during the next year on road construction, and in this connection it is interesting to note that an exhibition stretch of roadway is being built at Olympia, Washington, by various paving companies, each of which is laying a sample of roadway 66 feet wide and 100 feet long according to its own place and specifications which are filed with the State Highway Department. This stretch of roadway forms a part of the main highway north and south through the State.

**Ice on the Bath Atlantic.**—In addition to the work which will be done this spring and summer by one of our scout cruisers in patrolling the North Atlantic steamship route and reporting the appearance of ice, the Board of Trade has announced that the "Booth," formerly employed in the Scottish Antarctic Expedition, has been placed on the same service. The "Booth" carries a long-range Marconi wireless plant, which will enable her to keep in touch with the stations at Newfoundland and Labrador. The cost of this scout service is shared jointly by the principal Atlantic lines and the British government.

**An Automatic Stop Failure.**—The report of Sir Arthur V. Lee on a recent failure of an automatic stop on one of the tube railways of London makes it clear that the general principles of the automatic stop were not at fault. As compared with practice in this country, both the design and the upkeep were faulty. It was found that one of the three shafts of the winding shaft on which the stop arm is mounted was loose. Furthermore, the principle of control was wrong. In American practice, both the stop and the signal arm go to the danger position by gravity, should the service mechanism or short-circuit. In the case of the London tube installation, the mechanism was carried to the danger position by a spring.

**The Scottish Firth and Clyde Ship Canal.**—When the British Admiralty established a naval dockyard at Rosyth, just above the big cantilever bridge across the Firth of Clyde, it was urged that if a hostile fleet attacked the dockyard, the big light of the cantilever bridge would obstruct the channel and shut any warships that were at the dockyard away from the North Sea. The advantage of a canal in affording two exits to the sea has given new life to the agitation for the construction of a canal from the Firth to the Clyde. The government has decided however that while such a canal would have a certain strategic value, this would not be sufficient to warrant any large expenditure by the government upon such a proposition.

**The World's Largest Power Project.**—The State Engineer of the State of Oregon, the Hon. J. W. Lewis, has submitted a project for developing 30,000 continuous electric horse-power at Big Eddy, a point three miles above the Dallas on the Columbia River. At this location the river runs through a narrow gorge which could be closed by a dam only 300 feet long, and 180 feet above its foundations, and the construction of a canal 300 feet wide, 30 feet deep and a mile and a half in length. The head of water is 73 feet at low water and 42 feet at high water and the mean flow of the river throughout the year is 234,000 cubic feet per second. The hydro-electric units would be each of 32,000 horse-power. The total cost of the scheme would be about \$25,000,000.

**Electric Traction on British Railroads.**—The electrification of the Brighton Company's suburban railways, London, has given excellent results in the economy and the number of passengers carried. Comparing steam and electric traction, the number of trains in and out of Victoria Station in one day has risen from 408 to 790. At London Bridge the number has risen from 683 per day to 901. The number of passengers carried on the South London line since electrification has increased over four and one half millions each year over that carried during the last year of steam operation. The cost of maintenance of the overhead equipment has worked out at about \$107 per mile per annum, and the other conditions of maintenance are stated to be equally satisfactory.

**Engineering Activity in Argentina.**—Attention is directed to the many large engineering schemes which are about to be put through in Argentina and the opportunities which are open for competition by American engineering firms. Thus the municipality of Bahia Blanca is asking for estimates for a drainage scheme to cost \$1,500,000. A new water supply and sewerage scheme is to be undertaken in the capital which will cost over \$20,000,000. An important electric light and power plant will probably, according to the *Argentine Engineer*, be the outcome of the enterprise now being concluded between the governments of Argentina and Brazil for utilizing the Iguaçu waterfalls, which afford sufficient water-power to supply the two states and also the republic of Uruguay with light and fire "probably for a hundred years to come."

## Electricity

**Electric Power in Contracting Work.**—In contracting work in which power pumps, ventilating fans, wood and metal-working tools, air compressors, hoists, concrete mixers, etc., are used, the electric motor has been advantageously employed. The flexibility and versatility of this form of power have especially commended it for the temporary applications characteristic of contracting work. A Scotch contracting concern having a plan of reservoir work on hand recently made use of electric power by installing its own gas engine and suction-gas producer generating plant. During eighteen months' operation this isolated plant—comprising a 40-kilowatt generator, a 100-horsepower gas engine, and a 100-horsepower motor on the work and an installation of electric lights—consumed only 55 tons of anthracite coal.

**Metal-chrome.**—The electrolysis of lead melt produces peroxide of lead at the anode, and if deposited in films of varying thickness on polished plates beautiful color effects are obtained. (Gaston's process.) The electrolysis of lead acetate and an anode of a highly polished steel plate. This was laid on the bottom of a lead and covered with a cardboard perforated or not out in some design. On this was placed a copper cathode and a current from two or three cells run for ten or twenty minutes. The film of lead peroxide on the anode or steel plate displayed the most exquisite tints of the rainbow, due to the light reflected through the film from the polished steel beneath. The tints vary in color according to the light and the angle of vision at a window when a sheet of white paper is inclined over the plate.

**Sparkless Bell System for Mines.**—Telephone apparatus is likely to be dangerous in mines where fire damp occurs, not from any sparking in the microphone, as this appears to be harmless, but from the electric bells which are needed for the telephones. While it is true that some types of electric bell are brought out which are enclosed in gas-proof boxes so that the sparks cannot cause an explosion, it appears that in practice it is a very difficult matter to keep the sparks from emitting. An inventor, C. Pender, now designs an electric bell system so as to be entirely free from sparks, as he uses no moving contacts. For the current, he makes use of a special magnet, firing the armature and retaining it in position against the magnet. This magnet has no commutator or other moving contacts, but the wire comes directly off the coils. No sparks can therefore occur. For the electric bell he uses a polarized armature actuated by an alternating current magnet, so that the line current with the magnet stops, and no sparks are given.

**Wireless Telegraphy in Russian East Asia.**—At the end of December, 1911, the Russian Postal Department ordered three wireless stations for the northwestern district of Asia. Each station was to consist of two steel towers 250 feet high, with antennas and counterpoises, the towers and antenna sets of 24 horse-power capacity, a 15-kilowatt, 500-cycle, alternator-current generator, a transmitter of 75 kilowatts capacity and receiving an auxiliary apparatus. The three stations are now completed and have been taken over by the Postal Department, which has opened them up to public service. They are located respectively at Ochotsk, Nayan-shan, and Novomarinik. Ochotsk, situated about 1200 miles from Vladivostok, is a small town of three hundred inhabitants on the western coast of the Ochotsk Sea. Nayan-shan, which is about 1700 miles from Vladivostok, is an entirely uninhabited tract on the north coast of the same sea, while Novomarinik, at about 2,800 miles from Vladivostok, is a fishing hamlet on the north coast of the Behring Sea on the mouth of the Anadyr River. Nayan-shan and Novomarinik are touched twice a year by the mail steamers of the Voluntary Fleet.

**Horizontal Antennae.**—Kleblitz finds that wireless waves can be received with surprisingly good results by using antennas made up of wires stretched along a short distance from the ground, mounting the receiving devices at the center of the antenna. For instance, upon a large flat area near Berlin he stretched several wires between pairs of posts at about 3 feet from the ground. Having a combination of wires, he stretched one antenna from north to south, then a second from east to west so as to cross the first one at right angles in the middle. He also ran a third antenna across the middle point and directed NE and SW. He is at angles of 45 degrees. This latter antenna was about 1,000 feet long and lay in the direction of the Behning station (40 miles off), and also in the direction of the Eiffel tower, 500 miles away, and the German post of Brismensunde (180 miles). In this way he was able to pick up these two German posts, as well as the Netherland post, 250 miles distant. Signals could be heard very well from the Eiffel tower, and he concludes that an antenna of this length is equivalent to a vertical one of 40 feet height. Poldus was also able to pick up signals from the Eiffel tower from Bay by using a 4,000-foot wire 3 feet from the ground.

## Automobile

**Paris Forbids the Muffler Cut-out.**—Following the example of other foreign cities, Paris at length has made the light and bonnet the duty of muffler cut-outs in the Fair city will bring swift retribution in the form of the law. M. Leprieu, the Chief of Police, has just issued the edict making their use a misdemeanor punishable by fine or imprisonment.

**A Telescope Spring for Spring Wheels.**—In patent No. 1,050,197, also a form of Overhead-Frontal, Austria, Hungary, presents a wheel in which there is interposed between an outer rim and an inner rim coil springs which are housed within telescopic sections which slide upon each other as the spring yields in operation.

**A Spring-File Patent.**—Paul P. Wolst of Milwaukee, Wis. In patent No. 1,051,939 shows a resilient tire in which the tire casing includes spring bows arranged within the tire casing and fastened to rods which enclose the rim, suitable bars being employed in securing the several parts so that the casing distending spring bows will have their resiliency increased.

**Two Automobile-Tire Designs.**—Fred B. Carlisle of Malden, Mass., has secured two design patents, No. 43,453 and No. 43,454, for tires in which the first patent has variously resembling the links of a chain extending transversely across the tire and in increasing proportion while the second patent has rubber bands which extend around the circumference of the tire, the construction in both instances producing a non-skid surface.

**Where Germany Lags Behind.**—Despite the fact that Germany is proving ahead in the manufacture of motor cars, as evidenced by the fact that two of the largest companies recently have declared dividends of 25 and 27 per cent, respectively, she is still far behind in the number of cars per capita judging by England and France. In England, statistics reveal that there is one motor vehicle for every 249 persons, as against one for every 441 in France and only for every 627 in Germany. This state of affairs generally is reflected in the comparatively high taxation imposed on self-propelled vehicles in the Fatherland.

**A Policeman's Auto Lock.**—It is reported that a Washington city policeman profiting by his experience in connection with the motor automobile has invented a lock for automobiles for application in the ignition circuit in such manner as to form a part of such circuit. The improved device is said to comprise a rotary electrical switch which is controlled by a mechanical locking device which will not operate unless it does not interfere with the operation of the switch and which in addition to opening the switch lock may, by means of a suitable key form a part of the electrical circuit and the insertion of any key other than the proper one, will not permit the operation of the lock.

**Will Kerosene be Taxed in England?**—With the use of paraffin (kerosene) as a substitute for gasoline increasing, British users of heavy commercial vehicles view with alarm rumored threatened of a tax on paraffin, which up to the present time has been free. Already the authorities are "looking into" the matter with a view of suggesting the adoption of some such means. The paraffin question is a difficult one however for even if the users of motor vehicles did not find a small tax objection it would run hardily on the power plants, the depend upon it entirely for light. (Unquestionably it would never do to tax indiscriminately and there enters a most little problem in how best to diffit it.)

**Phenomenal Speed of Yesterday.**—In these days of phenomenal speed and the profit that goes with it in the perfection of motor vehicles, it is interesting to attempt to examine the records of the years gone by. As one example, for instance, it is recorded (officially) that as long ago as 1908 a speed of 121.04 miles an hour was attained in England in a match race between a Fiat and a Napier. This time the Fiat of the device, the Fiat on the Brooklands track and it never has been beaten to this day on the Brooklands track or on any other. The Brooklands track, he it added, is an oval approximately 2½ miles in circumference which makes plain that at times the Fiat was the winning Fiat must have been over 130 miles an hour.

**The Danger of Mechanical Policemen.**—An ultimate study of the ultimate effect of their own devices very probably would benefit those inventors who seek to alleviate traffic conditions by increasing the number of types of "mechanical policemen" designed automatically to slacken the speed of a vehicle or to create a great rumus immediately the legal rate of speed is exceeded. The inventors lose track of the fact that in a great many cases the "mechanical policemen" are not able to give quick acceleration. Often the time required to come to a stop to avoid collision is too short, whereas the catastrophe can be averted in nine cases out of ten by a short, quick burst of speed which for not more than a minute, may pass the limit of the speedometer will past the figure that marks the legal rate.

## Factory Methods of Testing Automobile Motors

### How the Testing Stand or Block is Used

By Stanley Petman, M. E.

**F**EW in these days of automobiloid know of the elaborate manner in which the engines that drive the cars are tested and tried before the purchaser ever buys of them. No engine is considered perfect until it has been run for hours and hours under the watchful eye of an expert mechanic, and now is turned out of the testing rooms until it has passed the final inspector's rigid examination, has had its horse-power 'piled' and has been duly tagged and recorded.

Naturally lengthy testing of the kind is expensive and there must be a very excellent reason for doing it. When an engine comes from the assembling rooms it is rough. Though its mechanical features may be well nigh perfect, the engine as a whole is 'rough,' it requires 'smoothing down' and those last final touches which transform it into a perfectly running machine.

Despite the advances in the perfection of automatic machinery, few and far between are two engines exactly alike. There are bound to be slight differences of adjustment, some bearings will be smoother than others, some pistons and cylinders fit a little better than others, one engine obviously is the best of the lot and it is in order to bring all the others up to that high standard, or to exceed it if possible, that careful and elaborate testing is necessary.

In factories where many cars are turned out every year, motors are tested on blocks arranged in rows. Generally the rows are scarcely more than a dozen feet apart, for space is always at a premium, where the reduction of overhead expense means much in the ultimate cost of the finished vehicle. The individual test blocks, too, are placed closely together with just enough room between them for the workmen to attend to their duties.

In all such large factories, efficiency engineering principles play an important part. Ignition apparatus, for instance, and gasoline and water connections, are fastened directly to the testing block. It is necessary merely to drop the motor into place, in small electric cranes is used for the purpose) and in a few seconds the gas and water leads and the ignition wires are attached. What are known in plumbers' parlance as quick detachable connections are generally used for the water and exhaust pipes.

All the motors have to be 'cranked,' of course. In order to perform this necessary operation some factory superintendents have hit upon a novel scheme which is the same in all cases except for slight modifications. As the motor testing blocks are placed in rows, with the motors all facing the same way, it is simple enough to fix tracks at the ends of the blocks and to mount a small car upon

A new method of ascertaining power delivered at the rear wheels of a car.

Motor test blocks in a western automobile works.

One of seventeen units in a motor testing department.

the tracks. On the car there may be an electric motor supplied either with suit able gearing and a short countershaft with a clutch device to grip the end of the motor crankshaft, or simply with a large pulley and a flat leather belt. Current for the electric motor is collected from overhead wires and two short trolley poles. Thus it is a simple matter to connect the electric motor with the gasoline engine in order to start it. The system has this advantage. The gasoline engine can be 'turned over' for an indefinite time while engine speed or ignition adjustments are made. Inasmuch as few new motors are more easily cranked than started, it must be conceded that such a system is extremely valuable.

Once the motors are on the blocks and running, it is the practice to permit them to run without load for periods which vary in length from four or five hours, where the factory output is large, and to 12 or 15 hours where the factory output is smaller and greater time can be devoted to the 'running in' process. Sometimes motors are driven for several hours by a belt placed over their flywheels before they are placed on the blocks to be run under their own power.

When motors are 'run in' under their own power 'light,' they are afterward placed on other blocks and a horse-power test taken by any one of several methods. In other cases, where the output is large and the time per motor for testing is more or less limited, it is the practice to couple them directly to electric dynamometers mounted at the back of the testing blocks. In this way the motors are run in under a load, while at the same time it is a comparatively easy matter to ascertain the horse-power they are developing at any moment merely by reference to a central switchboard to which all the dynamometers are connected. When such is the case, it is easy to obtain horse-power readings with the minimum of computation. Each test block is equipped with a revolution counter, and the figuring of the horse-power resolves itself into a simple problem in arithmetic, the voltage and amperage of the generators being known and 746 watts being recognized as the equivalent of one horse-power.

If the motors are not tested for horse-power directly on the first testing blocks, but are afterward placed on other blocks in order that the horse-power readings may be taken at different speeds, either an electric dynamometer or a fan dynamometer or a water brake or a Prony brake may be used for the purpose. Computations with either the water brake or the Prony brake are slightly more complicated than those necessary with an electric dynamometer, for which reason the latter is preferred. With a fan dynamometer, however, direct readings may

be taken from a dial, which method is the simplest of all—simplest because it is known that with the fan vane set at certain distances from the center of the carrying arms a certain amount of power will be required to drive the fan at certain speeds. Given fan speeds corresponding with given horse-powers, it is merely necessary to convert the fan speed into horse-power directly by means of a table.

For the taking of even more careful tests, there re-

the indicator with other diagrams known to be theoretically or practically correct. Similarly, incomplete combustion, which is a fault of carburetion or improper timing, and also incorrect timing or faulty ignition can be detected readily by means of an indicator diagram. The proper use of such apparatus, particularly on internal combustion motors, requires the greatest of care and considerable experience. Errors are so likely to creep into the results obtained even where the oper-

taken in conjunction with the horse-power tests.

In a number of factories, testing on the blocks, supplemented by horse-power tests, is considered insufficient, and motors are given a further test after they have been placed in the chassis. There are several ways in which this may be done. Either the motor may be fastened down on its bed in the chassis and coupled up to an electric dynamometer through the intermediate of the propeller shaft and the transmission gears,

Factory methods of testing automobile motors. Setting an engine on a stand in the testing room.

maine the indicator, an instrument which gives a graphic indication of the conditions within the cylinders during the operation of the engine. With such a device it is possible to ascertain just when the motor is operating at its best, when it could be made to operate at greater efficiency, just what the trouble is and how best to remedy any or all faults. Thus, for instance, sluggish opening or closing of the valves will be made apparent by comparing the diagram taken by

motor is thoroughly qualified to make the tests, that it is rarely used except to "set" a new motor of a new type. Older motors, of course, can be set from the other, reference being made to the timing of the valves and ignition. The indicator also is very valuable in ascertaining the performance of motors which are still in the experimental stage, such as motors in which the stroke to bore ratio is greater than any that has been attempted before. Generally, indicator diagrams are

or, with the rear wheels jacked up, belts may be placed around them leading to fan dynamometers. In this way not only is the motor tested, but all of the transmission elements are tried out at the same time. A test of this kind is nearly, though not quite, equivalent to a road test.

Still another method is to place the completed chassis, fitted on a platform constructed for the purpose, the rear wheels resting on rollers and the front wheels

rolling in chocks shaped to fit them. The rollers upon which the rear wheel rest are geared to an electric dynamometer by means of a chain. Under this method, which provides a rigorous and thorough test for the whole of the transmission mechanism as well as the motor, the operator remains seated in the driver's seat of the car with the voltmeter and ammeter on a stand set in front of him. Consequently he is enabled to tell at a glance exactly what setting of spark and throttle levers is productive of the best results and under what condition of carburetor adjustment the motor can be induced to generate its maximum power. The readings taken, of course, represent the actual horse power delivered at the rear wheels, and as it is in this figure which counts most for all it may be appreciated that the test is thorough. If it transmission inefficiencies may be ferreted out, clutch troubles detected and remedied the cooling and ignition systems given a careful test in the chassis and, what is even more important, the lubrication of all moving parts except the bearings in the front wheels tested. Finally, brake efficiency can be tested by the very simple electric motor drawing current for the purpose from the lighting mains.

In connection with the method of employing the electric dynamometer for measuring horse-power it is interesting to note that in several factories arrangements have been made to put the current generated to some useful purpose. In one large factory in the West where production activities are centered in the manufacture of heavy farm tractors, practically all of the current used in running the machinery of the plant is obtained from the dynamometers driven by engines on test. Frequently now are being made to enlarge the testing sheds. One of the principal reasons for the expansion is to permit the use of all current drawn from machines on test. In this way two thirds are killed with one stone, so to speak. The motors are thoroughly tested the current used is employed in reducing the running cost of the factory, and the net result of the lowered overhead charges is reflected in the lower production cost and the lower selling price of the vehicles.

But to get back to engine testing. All such shop testing of course is merely preliminary to the road test. Regardless of what a shop test may show, no man can tell how that machine is going to operate on the road, probably in the hands of an inexperienced driver. Consequently they are ultimately mounted in test chassis and sent out over the roads in the hands of a corps of road testers, whose instructions are to abuse them. It is their duty to seek out the weak spots (there is no such thing as a perfect car) and point them to the factors upon which they rest. Naturally, these road testers are experienced men perfectly able to cope with very nearly every kind of trouble that may arise short of actual breakdown.

### The Lexington Avenue Subway Four-track Tunnel Under the Harlem River

THE construction of the Lexington Avenue four-track subway calls for some important subaqueous tunneling below the Harlem River. At this crossing it was necessary to maintain a depth of water above the roof of the tunnel of thirty feet at mean high tide and the tunnel will be constructed to clear this level and will be built with a low crown on each approach. The method of construction will differ radically from that followed in building the various tunnels beneath the Hudson and the East Rivers, where the work was advanced by the use of compressed air and the crowd head shield. At the Harlem crossing the structure will consist of four separate steel tubes, embedded in a

monolithic mass of concrete and heavily lined with concrete on the inside. When it is completed, its cross section will present the appearance shown in the accompanying drawing, and it will have a total depth of 24 feet 6 inches, and a total width of 78 feet.

The first operation will be to dig a trench across the bed of the river, which will be 74 feet deep, that is to say, the bottom of the trench will be 34 feet below the original bed of the river, and the width of the trench will be 80 feet. The total length of the steel tubes when they are in place will be 1,960 feet. The tubes, four aligned, will be built in five sections, four of which will be 220 feet long and one, 200 feet. They will be constructed of 3/4 inch steel plates, the contiguous sides of the tubes being dished in order to reduce the total width of the four as thus assembled. To preserve the tubes in their relative positions and keep them true to form, transverse diaphragms of 3/4 inch steel will be riveted to them at every 15% feet of their length. Along each side of the structure, these diaphragms will be bolted to vertical side walls, formed of 4 inch by 12 inch planking, backed by 10-inch by 12-inch timber flumes, one such flume opposite each

lowered away until each end rests on a grillage prepared at the bottom of the trench to receive it.

The top of the grillage platforms upon which the steel structure rests, is about two feet above the bottom of the trench, and the first operation before the buoyancy cylinders are detached is to fill in this space with concrete. The buoyancy cylinders are then completely filled with water and are released from the main structure. It is then necessary only to blow out the central compartment of these cylinders and they come to the surface by their own buoyancy.

The next operation is to fill with concrete the pockets formed by the diaphragms and the side walls. This is done by means of a big scow of the same general type as that shown on our front illustration, which represents the plan adopted in building a two-track tunnel of the same general character beneath the Detroit River. It should be stated here that the method of constructing these tunnels was devised by Olaf Hoff, C.E., who first applied his method in the successful construction of the Detroit River tunnel above referred to. The scow for use in constructing the Harlem River tunnel will be 25 feet in width by 110 feet in length.

At its center will be a two-story structure containing the concrete mixers, and in front of these, erected along the side of the scow, will be five elevator towers of the type shown on our front page engraving. The towers will be so placed that each one, when the scow is in position, will stand immediately over one of the spaces between the adjacent tubes, or between the outside tubes and the side walls above described. Within each tower will be a bucket for holding the concrete, and on the outside of each tower will be attached a large pipe which will lead down into the particular pocket which is being so erected.

The concrete material, broken stone, sand and cement, will be brought to the scow in lighters, loaded into barges along the roof of the concrete mixing house, raised, and then loaded into the buckets in the respective towers.

When the buckets are raised to the proper level opposite the funnel-shaped top of the concreting tubes, they will be automatically tripped and will discharge their liquid contents into the tube. The bottom of each tube will descend somewhat to the surface of the liquid concrete that has already been deposited, and the concrete will be of such fluid consistency that it will readily flow and find its way into the whole pocket.

Means are provided for raising the tube as the level of the deposit in concrete rises, and the work goes on uninterruptedly until the whole mass has been completed flush with the top of the diaphragms.

One incidental advantage of this method of concreting is that the concrete sets under a heavy hydrostatic pressure, which in the present case ranges from 22 pounds to the square inch at the bottom of the tubes to 26 pounds at the top. This heavy pressure serves to thoroughly compact the concrete. When the specimen of the concrete laid by this method in the Detroit River tunnel, it is a core cut from the hard end deposit and polished. It is remarkably compact, and the constituents are well distributed.

The laying and concreting of the cylinders will come success from the center and will be carried toward the ends. When the whole job is completed, the water will be pumped out from the tubes and they will be ready for their interior lining of concrete, which is 18 inches thick on the sides and 16 inches thick on the roof.

The total cost of the tunnel will be \$1,000,000, and the contract time for completion, about three years from the present date. The contractors, however, are confident that it will be finished several months before that time.

steel diaphragms. The wooden sides will be fastened to the structure by bolts which will pass through the 10-inch by 12-inch flumes and through angles riveted to the outer edges of the diaphragms.

Each four tube section will be built on staging erected within one of the adjoining dock slips, the staging consisting of four longitudinal rows of piling finished off with longitudinal caps. When the steelwork of a section is completed, a series of scows, each measuring 14 feet by 80 feet, will be floated in between the piles, at low tide, and as the tide rises, the scows will have sufficient buoyancy to lift the tunnel sections clear of the staging. It should be mentioned that the ends of the tunnel tubes will be temporarily closed by wooden bulkheads, as shown in the illustrations. The section will then be towed out into the stream above the position in which it is to rest on the river bottom, the scows will be scuttled and withdrawn, and the structure will be left floating by its own buoyancy.

Before sinking a section, four buoyancy cylinders are strapped across the ends of the tunnel section, two at each end and water is admitted, first to the tunnel tubes themselves and then to the buoyancy cylinders, until the latter are just awash, at the surface of the water. Two floating derricks will then take hold of the structure, one at each end, the remaining buoyancy will be further reduced, and the whole structure will be

## The Control of the Mississippi

To the Editor of the SCIENTIFIC AMERICAN

Some features of the editorial, "The Problem of the Mississippi River," in the SCIENTIFIC AMERICAN of January 1918, should be important from all viewpoints, for of course the subject is as important that the fact that it is too much light or too much thrown upon it. In the editorial this statement appears:

"As a matter of fact, what takes place is this, when the floods come down, the deep pools are scoured out and the material is deposited on the shoals further down the river, causing a temporary raising of the bottom at those points. As the river falls, the action is reversed, the bars are scoured out and the sand is deposited in the next pool. Careful surveys for several decades show that not only has there been no raising of the river bed, but the cross section has slightly increased."

Please observe  
"Col. Butler considered it safe to assume that fully 400,000,000 cubic yards of material came out of the Missouri River in twelve years. This was the estimate of the Select Board of Engineers on Survey of the Mississippi River, Document No. 50, 61st Congress, 1st Session, H. R."

"Other observations indicate an outflow of sediment and rolling material of about 30,000,000 cubic yards per year from the Ohio River, about 5,000,000 cubic yards from the Arkansas River, and about 6,000,000 cubic yards per year from the Red River." (The same page.)

That is to say, our best authorities indicate 447,000,000 cubic yards of material projected into the lower Mississippi, taking no account of the discharge of material from such streams as the St. Francis, Yazoo, White, Hatchie, Osage, Kanabaska, upper Mississippi, and countless minor tributaries.

The Mississippi discharges into the Gulf of Mexico a possible 300,000,000 cubic yards, which leaves 150,000,000 cubic yards at least to dispose of between the Gulf annually. Light sediment is washed on into the Gulf, behind it follows the vast river of gravel and sand, and in between the levees as you may have observed, say at what is left of Island No. 10, just above New Madrid, and say at Wolf Island and Plum Point Reach and other points, with diminishing size of particles down the river, almost gruel and horridly red mud, and in the lower river. Of course, sand does find its way into the Gulf, say 30,000,000 cubic yards. (P. 70 "Leaves of the Mississippi," Government Printing Office, 1887.)

Compare this 300,000,000 cubic yards of heavy material flowing out the passage with the 210,000,000 cubic yards of sand and gravel coming out of the Missouri along p. 47, Doc. No. 50, also referred to) and it seems clear that the position of the SCIENTIFIC AMERICAN is not according to the facts with regard to the grave question of the cross section between the levees of this day and to come. Indeed, in view of the geological history of the Mississippi bottom, I am not a little surprised to see a position taken that is so clearly and easily demonstrated as untenable. Of course, in taking this position, the authorities consulted were most trustworthy before survey and divers committees, and not the original documents containing the figures, at least so it seems to me after carefully considering the deductions, without knowing from what data they were made. The Mississippi bottom is largely alluvial, and the levees and the deposits have not changed at the bottom of the levees and of those who demand the maintenance of the ordinary levee projects in the Mississippi bottoms.

Of course, the question of profit is one for mathematicians to answer. If the profit of a levee system, so solid and as a matter of fact, is sufficient to make up for the inevitable disasters due to toppling the levees at some source or farther date in the future, very well, but we should not enter upon a vast expenditure of money and with strict neglect of the fundamental and indisputable fact that the levees inevitably fill. Indeed, provision is already being made for this condition, the levees are being thrown up farther and farther apart, because of rising floods. I need not discuss the cause of these apparently increasing floods, nor the probable increase of the fine sediments due to wash of eroded lands, etc. Neither is it necessary to rumble the Mississippi valley students that between the levees now the most fertile of Mississippi bottom lands, while at the levees recede from the eroding banks and the eroding and eroding water they are even stronger on the better lands, eroding the cotton and other plants farther back into the swamps. That is to say, millions of acres of land between the levees is utterly washed under the present method of levees.

The proper consideration of the narrow chute between

the levees in the lower valley serves to emphasize the comparison to a spillway over a dam, the levees effectively damming the river and ponding the water in the swamps and up the tributaries and main river.

The editorial under discussion did not mention, of course, to say that 2,300,000,000 cubic feet per second is the river flow. The annual discharge varies from about 11,000,000,000 to 30,000,000,000. The per second discharge of 1900 reached 1,777,000 cubic feet. I am experiencing considerable difficulty in getting recent public documents on the subject, there being apparently no catalogue covering so important a matter as public documents relating to the river. I judge however, that it is stated that a second flow of 2,300,000 cubic feet has been observed. Now this is 523,000 cubic feet per second more than the previous record of 1,777,000. Before accepting these figures, it is essential that we know whether the observations were made on the date of the flow, or whether the old river section for the point of observation was used in estimating the flow. The passing of a wave of sand at the time of the measurement would very nearly account for the apparent tremendous increase in flow over the previous record. I observed in reports of the flood last spring that the sounding stages on the Ohio and Mississippi apparently did not indicate any such increase, and I tentatively ascribed the excessive discharges to the filling of the river bed and to the ponding of the increased length of levees preventing the usual outflow at the outlets of various sections.

I feel certain that the figure of 2,300,000 cubic feet is not accurate. Such a figure would, of course, indicate that the levee system is not to blame for the ominous work last spring, but the figures should not be accepted without a thorough and unbiased study of the conditions when they were made, the point at which they were made, the circumstances under which they were made, by whom, and, as heretofore remarked, whether or not the same section or cross sections had been greatly changed, due to local or general fill and scour conditions. It is interesting to observe that the river flow varies from 97,000 to 1,777,000 cubic feet per second at Warrenton, Miss. (Tabulated Results of Discharge Observations, 1906.)

I presume that the matter of a setting pond in the Missouri has been considered in connection with the reviving of the lower Mississippi. This would stop the river of gravel and sand which menaces the lower river levees, and reviving the river banks, on page 2478, Report of the Chief of Engineers, U. S. A., 1906, is as delicious a bit of humor as ever appeared in a solemn public document. Speaking of the works in Louisiana Bayou, 522 miles below Cairo, on the right bank, it says:

"The total length of the original work was 15,820 feet, of which about 4,000 at the lower end has been destroyed by about half the remaining work is protected by a large mass of land."

There is plenty of frankness and explicit detail in the report made by the Chief of Engineers, U. S. A., and a quaint humor is occasionally discernible, especially when the men who know find themselves thwarted by those who don't.

Certainly what I have said is not an argument against the proposition to turn the whole Mississippi River project over to the army engineers now digging the Panama Canal. Give them full charge and complete freedom, only let us have a thorough understanding of the situation of the matter, without compelling the men who know to reveal their personal feelings of humor as I have quoted in order to indicate the conditions under which they toil and the constant, if locally profitable, folly imposed upon the country by the present project of the levees. I need not add that I am open to discussion with regard to the levee system, a plan or project, only the plan should coincide with figures and facts already a matter of axiomatic record.

Little Falls, N. Y.

## The Co-operation of Capitalists and Inventors

To the Editor of the SCIENTIFIC AMERICAN

In order to have progress we must invent, and in order to invent experimenting is necessary, and to carry out experiments capital must be expended.

The greatest handicap of the young American inventor-to-day is the lack of capital. It is a well-known fact that there are few real inventors who have means of promoting their inventions, for the sons of the rich never think about designing or inventing any machine to save time and labor, as their minds are employed in seeking ways to spend what they have for pleasure, however, there are exceptions to this rule. A great many persons object to the idea of taking their inventions to men of means for promotion, as many inventors have lost not only their patent rights, but much time and money that was spent in perfecting some useful machine or device by taking it to some unscrupulous party with the object of getting financial aid. There are hundreds of useful and much-needed inventions that never got on the market on account of the inventor

not being financially able to place them in the channels of trade, so the patent and invention is dropped and the world never gets any benefit therefrom.

What I believe to be the most needed in the United States is co-operation between honest capitalists and competent, reliable, and progressive inventors, with thorough patent laws in a systematic way that will protect patentees and inventors to the extent that they will have a fair showing. This would do more for the advancement and progress of the country than all the technical schools combined.

## The Neglected Study of Muscular Energy

To the Editor of the SCIENTIFIC AMERICAN

Those of us who give much attention to the contents of newspapers and popular periodicals cannot fail to notice that as time goes on the space given over to popular presentations of scientific subjects tends steadily to increase. Not only are we made acquainted with the more easily understandable features of novel inventions and the results of original research, but in addition, general outlines of the probable future course of invention and discovery are common.

If inquiry were made, as to what special branch of science of most vital importance to the human race, probably would probably be given to the study of the human body.

Again if the question were put as to what generalization of modern science has influenced thought in the greatest degree, the law of conservation of energy must surely be mentioned.

Having regard to these considerations, it is not remarkable that comparatively little is to be found in print with relation to the conservation of energy and the phenomena of muscular action.

Reference to the expenditure of energy by the human body are abundant in the energy in question being supposed to be derived primarily from food. Consideration of the law of conservation of energy would suggest that the body may sometimes receive energy in the form of mechanical work, as when a weight is lowered gently, or a cleaved hand forcibly upon it. An elementary knowledge of mechanics must convince us, that muscular action may be divided into two classes, namely, the performance of mechanical work by the muscles, and the performance of mechanical work by some outside force against the action of the muscles. A little reflection will show that the number of muscular actions falling under the latter classification is not inconsiderable, as might be supposed by some.

Whether or no the human body is able to make use of the energy expended upon it, and in what form, would appear to be of vital importance, yet in popular modern literature little reference is to be found to this consideration. Usually the average person would dismiss the subject with a wave of the hand, remarking that the energy must be turned into heat. Personally I cannot believe that this conclusion would be well founded.

## The Prone Position for Aviators

To the Editor of the SCIENTIFIC AMERICAN

A few weeks since I was asked by an Aviator, "This idea was first put in by the Wright brothers, who soon gave it up as unsatisfactory. Lying in a prone position, one cannot exert as much force upon the control levers or direct the traverse tipping of the machine as well as when sitting upright." It would seem, therefore, that the prone position would be a disadvantage to the aviator lying in a prone position an unobstructed view. Flying down from a high altitude the position would be very uncomfortable, as the aviator would be literally standing on his head. But why the prone position, anyway? A well-designed stream line body can be made deep enough to permit the aviator to sit up with his head protruding and will not offer undue resistance to the wind.

DAVID JASCO

## Astronomical "Bulls" Again

To the Editor of the SCIENTIFIC AMERICAN

Your French Astronomer and his peasant recall a "bull" made by two still more famous men. In Art V. de la Colombe, I, Colombe, a French body that would "bull" this passage occurs.

"That single glimmering yonder  
Is from Camopola, and therein  
Is Jupiter."

Coleridge has a long footnote on the passage, but finds nothing amiss in it, and if there is any reference anywhere in literature to this particular "bull," it has escaped my eye.

Detail view of the power house of the Strawberry Valley Irrigation project, Utah.

## The Great Irrigation Project at Strawberry Valley

### A Remarkable Engineering Task

By Newton Forest

THE Strawberry Valley Irrigation project being carried out by the United States Reclamation Service is in many respects one of the most remarkable pieces of engineering in the world. Building a four mile tunnel through a range of mountains and picking a river from one valley and making it flow through this tunnel into another valley is an undertaking even greater than diverting the waters of the mighty river Ganges in the construction of the Panama Canal. But that is precisely what has been done.

The Mormons went into Utah Valley in the early fifties and laid out their farming the stream that flowed down from the mountains into Utah Lake. For a time their small ditches sufficed for their agricultural needs and they prospered. As the population grew the ditches were enlarged and extended, until a very small drop of water was required to meet the demands of the irrigators. In years of scanty precipitation there was short age in the crops, crop yields were diminished and the late comers frequently lost all. Under these conditions no further development of the valley was possible, yet there were thousands of acres of land just as fertile as any in the valley, which without water were useless. Beyond the Wasatch range of mountains, which rims the valley's eastern border, Strawberry River for centuries has run unobscured by its water flowing into the Colorado River. The rugged range of snow-capped mountains imposed a seemingly insuperable barrier and to divert the flow of the river into the thirsty valley was the gigantic problem solved by the construction of the tunnel a huge bore nine by ten and a half feet and approaching four miles in length. This tunnel has just been completed, and when the sparkling waters rush through it down the sloping valley a literal transformation in the physical geography of the State of Utah will have been accomplished.

With one exception this underground waterway tunnel is the largest in the world. Many hard engineering problems had to be overcome in planning it and great physical endurance was required of the men who carried out the work. The tunnel pierces the solid rock of one of the

Looking through the four-mile tunnel which will divert a river from one valley to another

Haying on ranch near Mapleton Bench. The alfalfa yield is four tons per acre. Three crops each season.

highest peaks of the Wasatch range and diverts the water from one drainage basin to another forty-five miles away. The country where the work is being done is of a sort to add to the difficulties. For five months a year the construction camp is cut off from the rest of the world on account of the heavy snowfall. However, notwithstanding all the difficulties, a remarkable record of economical as well as rapid construction was made on the tunnel. In a single year more than 5,000 feet were driven and lined with cement. Before construction on the project could begin thousands of square miles of valley and rough mountain country were surveyed and mapped and the tunnel and canal lines marked out. A telephone line some forty miles long, extending from Spanish Fork to both portals of the tunnel, was constructed, as was also a wagon road of the same distance. Down in the foothills a diversion dam was thrown across Spanish Fork River and the waters turned into a power canal three and a half miles long, which dropped them through huge pipes on the big turbines 100 feet below. Power thus generated was transmitted electrically to the tunnel site, where it was used to turn the diamond drills, light the camps and run the heavy machinery. The camps are located a mile and a half above the level of the sea, and the work is carried on day and night in three shifts.

Beyond the tunnel, in the shadow of the granite peaks, a great reservoir is being constructed. A retaining dam 71 feet high and 400 feet in length of rock, cement and steel is being built for the impounding of the waters of Strawberry River and for the purpose of discharging them through the tunnel into canal systems leading to the arid lands of the valley. The reservoir formed by this big dam will have a capacity of 200,000 acre-feet, or sufficient to cover that many acres a foot deep.

The progress of this work has been full of dramatic and thrilling incidents. The excavation of the tunnel required the constant vigilance of the engineers and the utmost precaution to prevent floods. Subterranean lakes and springs were opened by the dynamic blast, and the

burst of water frequently drove the workers precipitately from the tunnel. Cave-ins threatened injury or death, so that the concrete lining had to follow closely the drift. Notwithstanding all the difficulties confronting the Reclamation Service is completing its work in record time, and it remains now for the landowners in the valley to carry out their obligations, the first one of which will be the sub-division and sale of all individual hold-ings in excess of 160 acres of the lands irrigated.

The valley to be irrigated is especially interesting because it is the scene of the earliest irrigation by Anglo-Saxons in the West. Settled by Brigham Young and his followers after their march of more than a thousand miles into unknown territory peopled by savages, it is the oldest example of community farming by an English-speaking people in the great West. The attractions of this part of Utah are numerous. It is said to be one of the most beautiful valleys in the world, rivaling the best Switzerland can produce. It has a fine climate, a soil of known fertility and adapted to the growing of a large variety of profitable crops. It is the land of peaches and the big red apple, and promises to be a valley of small farms intensively cultivated, thus insuring a prosperous and prosperous community where conditions will be more suburban than rural and where people will delight to dwell.

### A Skyrocket Flying Machine

**F**ROTHMAN LAW, known for his foolhardy daring feats in the air, surpassed himself in recklessness on the ominous 13th inst.

Law attempted to ascend in a giant skyrocket to a height of several thousand feet, tumble out, and descend safely by means of a new safety parachute. This parachute, the invention of A. Leo Stevens, has been used by Law many times for making perilous jumps, such as from the Bankers' Trust Building and the Williamsburg Bridge in New York city and from a biplane at a height of a mile.

The parachute mentioned is made of Japanese silk, and is carried on the back of the aviator like a knapsack. It is claimed that a 5½ pound parachute will carry a 170-pound man safely. The mere act of tumbling out of an aeroplane causes the parachute to open automatically. Law has used it many times, and always without a hitch.

The skyrocket which was to elevate the reckless Law was some 3 feet in diameter and 10 feet in length. It was carried on a heavy trailer some 20 feet in length, forming the stick. A seat was provided in its upper end for Law, who sat inside the tube and was covered by the pointed top. The lower half of the skyrocket was constructed of sheet steel and was partially filled with fifty pounds of slow burning powder—enough, it was supposed, to send the rocket with its human load 3,000 feet skyward. Unlike ordinary skyrockets, this giant structure was loaded at the head, so that it was top-heavy. It was placed beside a framing of heavy timber, as shown in one of our pictures.

After Law had taken his seat and put the cap of the rocket in position, the fuse was lighted. It sputtered for some time. Then followed a terrific explosion. The

mass, instead of expanding downward as expected, burst the steel shell into many pieces. Law fell like a sack to the ground, a distance of approximately 15 feet. The parachute had no chance to open. Law was badly burned and was rushed to a hospital. He announced his intention of making another trial in

the near future. Needless to say, the performance was arranged for the purpose of making a sensational newspaper picture, and several cameras recorded it. In this respect it was similar to Law's ascent in a balloon above the Hudson River and blowing up of the balloon with dynamite while in midair, which he accomplished without mishap several months ago.

The explosion. The gases expanded in every direction, hurling fragments of the rocket many feet.

Law in place in rocket before putting on the cap.

Several men were needed to carry the heavy rocket. Carrying the rocket to be set up.

Note his aviator's helmet and the top of the rocket at his feet. Law lying unconscious at the foot of the frame.

### Wilhelm Kress, Aviation Pioneer

**W**ITH the death of Wilhelm Kress, nearly a month ago at Vienna, the oldest aeroplane pioneer passed away. Kress was born in St. Petersburg on July 20th, 1848. His father was a manufacturer and the son engaged in piano building. At the age of twenty-eight Kress became interested in the problem of dynamic flight. One day while flying a kite when there was very little breeze the exertion he was put to before the kite would soar caused the young inventor to figure out a way to make it go up of its own accord, wind or no wind. Already in 1864 he had made his first air propeller. The idea came to him to fit propellers to a kite, do away with the string entirely, and become independent of the breeze. His first model brought out in the early '70s, was propelled by a clock spring. Not till 1877 did he make a model which flew successfully. This was propelled by elastic bands

and consisted of an aeroplane surface with twin propellers and a rudder for stabilizing purposes. Three years later Kress made public flights with this model. In 1901 at the age of 52 he spent three years attending lectures in the technical high school in order to perfect himself in mechanics. He had made numerous models which had flown, and now he wanted to produce a practical man-carrying machine. With the backing of the Emperor Franz Joseph, he was enabled to order a lathe motor. It was supposed to weigh under 400 pounds, but when finally delivered it weighed 830 pounds. Nevertheless, Kress mounted this heavy gasoline engine in his aeroplane, and tried out his machine. Unlike Maxim, Kress experimented on the water. His machine rose in the air, but collapsed owing to improper balance. The inventor got a ducking but emerged unscathed. But he was never able to explain the reason for his upset so that people would believe in him and back him still further. He had spent \$25,000 most of it supplied by the Emperor. Without funds he could do nothing, and he was obliged to sit idly by and see others solve the problem of human flight when success was in his grasp.

During the last years of his life Kress was honored as a pioneer. He was an honorary member of the Aero Club of Vienna and of several technical organizations. Nevertheless, he died a poor and broken-hearted man, but not before he had witnessed the coming of the hydro-aeroplane—the machine of which he was in a sense the original inventor.

Such is the fate of many an inventor who's thought after in France, though he saw few Kress, was like him hopelessly "shelved."

The Presidency of the British Association for the meeting in Birmingham (September, 1911), made vacant by the death of Sir William White, has been filled by the appointment of Sir Oliver Lodge.

# The Heavens in April

## Do the Pleiades Shine Through a Haze of Star Dust?

By Henry Norris Russell, Ph D.

AN INTERESTING observation has recently been published in one of the *Bulletins of the Lowell Observatory* which relates to the nebula in the Pleiades. It has long been known that this conspicuous star cluster was surrounded by faint nebulae. Only a few of the brighter parts of this are visible to the eye, but photographs of a couple of hours' exposure show that extensive areas are covered by faintly luminous filaments and streaks, which are often very parallel and close together over a considerable region. Longer exposures bring out extensive nebulosities extending far beyond the visible limits of the cluster.

These nebulosities are considered about the brighter stars of the Pleiades, and some of the fainter ones—such as  $\gamma$  and  $\delta$ —it cannot be doubted that they are really connected with the group. But until the recent work of Mr. Milner at the Lowell Observatory nothing was known of the real nature of these faint clouds of light. Their general appearance on the photographs resembles that of the Great Nebula in Orion, which is known to be gaseous and also certain other filamentous nebulae in the Milky Way, whose spectra contain the characteristic bright lines of the gaseous nebulae. So it would be natural to suppose that, in the Pleiades also, the stars are accompanied by wisps of self-luminous gas.

But the actual fact shows another state of things. Very long exposures are necessary to obtain properly exposed photographs of the spectra of such faint objects. But Mr. Milner's technique was equal to the inherent task of exposing, on a plate in a suitable spectrograph attached to the 24-inch telescope for twenty or thirty hours, on three consecutive nights the slit of the apparatus being so arranged that only the light from one of the brightest parts of the nebula about three minutes of arc from the star *Merope*, centered the spectrograph while the light of the bright stars of the cluster was on the slit excluded.

On developing his plate Mr. Milner found a distinct spectrum quite different in character from that of any previously known nebula. The spectrum is in the main continuous but is crossed by dark lines which can be identified with certainty as those of hydrogen and helium—the hydrogen lines being much the stronger. As the discoverer puts it, this is a true copy of the spectrum of the brighter stars in the Pleiades—so much so in fact that careful tests had to be made to determine whether diffused light from the bright stars may not in some way have got into the spectrograph.

Such tests, made on Sirius, which has no nebulae now, showed that the diffused light was certainly not strong enough to produce any visible effect on the plate. From this it is concluded that the brighter parts of the nebulae of the Pleiades shine with light which is exactly similar in spectroscopic character to that of the brighter stars of the cluster.

Just a spectrum of this sort, with dark lines on a continuous background must arise originally from a hot body surrounded by an absorbing atmosphere—in other words from a star, or many stars.

Accepting this there is mainly two hypotheses to explain the fact. One is that the light behind the Pleiades, and probably very far behind the real star clusters of stars, just similar in spectrum to the Pleiades, but so numerous and so far off that they appear to form a continuous haze in the sky. This is exceedingly improbable and when it is considered that the observed nebulae extend strongly to group itself about certain stars of the Pleiades group the assumption that innumerable distant stars, far behind, are so arranged in the heavens that as seen from the perspective station in the universe they seem to group themselves around those individual stars becomes too absurd to entertain.

The other alternative is to suppose that the nebulae in the Pleiades consist of gaseous matter, perhaps of meteorites or fine dust, which accumulates the stars of the cluster and shines by their reflected light. This is free from the difficulties just mentioned, and makes it very natural that the nebulae should seem brighter out near some of the brightest stars. Other bright

stars are nearly clear of the nebula, which, on this hypothesis simply means that there is little of the reflecting material near them.

A strong confirmation of this theory is found in the fact (which has long been known) that there are much fewer very faint stars in the region of the Pleiades than, on the average, in equally large regions of the sky. Such stars are undoubtedly for the most part very remote from us, and far behind the Pleiades, and it has been suggested long ago that the nebula associated with the group were only partially transparent, and so dimmed the light of the stars behind them, and hid all but the brighter ones. In the light of present knowledge this seems very probable.

One question remains. Can the light which the nebulae material receives from the Pleiades be strong enough to produce an observable effect, after reflection from scattered particles of matter with wide spaces between them? The answer is in the affirmative for Mr. Milner shows that in the region of the nebula whose spectrum he photographed, the total amount of

visible light in the west) Orion, too, is almost gone, but Gemini and Auriga, with Canis Minor to the north ward, still make a fine showing in the western sky. Leo and Virgo are high in the south with the enormous moon length of Hydra below, and the small but conspicuous figure of Corvus on its back.

Still lower down we, in our northern latitude, may see a few stars of the Centaur, and observers south of the twenty fifth parallel of north latitude may see the Southern Cross directly below Corvus on a line drawn through  $\gamma$  Centauri (which last star is just within the limits of our map).

Below  $\gamma$  and  $\delta$  Centauri observers in these same latitudes may see two very bright stars,  $\alpha$  and  $\beta$  Centauri. The brighter of the two—and the one farthest away from the Cross—is well known as the nearest star in the heavens.

Serpens and Ophiuchus are rising in the southeast and east, and Cygnus and Lyra in the northeast. Hercules, Corona and Bootes occupy the eastern sky above these. Camelpota and Cepheus are low in the north. Ursa Minor and Draco to the right of the Pole, and Ursa Major almost overhead.

### The Planets.

Mercury is morning star all through April, but is south of the Sun and poorly placed for observation. He is at his greatest elongation on the 24th, and rises about 4 20 A. M.

Venus is evening star at the beginning of the month, setting a little after 9 P. M. She is however rapidly approaching conjunction and becomes less and less conspicuous every night. On the 24th she is in inferior conjunction, passing apparent by about 6 degrees north of the Sun, and after this time she appears as a morning star, though she will not be easily visible until next month.

Jupiter is morning star in Sagittarius. He is in quadrature with the Sun on the 6th, but being very far south, does not rise till 1 30 A. M.

Saturn is evening star in Taurus, setting about 9 30 P. M. in the middle of the month. Uranus is in Capricornus, and in quadrature with the Sun on the 24th but being in 10 degrees south declination is observable only for a short time before daybreak.

Neptune is in Gemini observable in the early evening. He is also in quadrature, on the opposite side of the Sun, on the 13th.

The Moon is now at 1 P. M. on the 6th, in her first quarter at 1 A. M. on the 14th, full at 5 P. M. on the 20th, and in her last quarter at 1 A. M. on the 28th. She is nearest us on the 18th and farthest away on the 2nd and 30th. As she sweeps around the sky she passes Mars on the 2d, Mercury on the 8th, Venus on the 16th, Saturn on the 18th, Neptune on the 19th, Jupiter on the 26th, and Uranus on the 27th.

On Sunday, April 6th, there is a partial eclipse of the Sun, visible at Washington, but observable as a small partial eclipse in northern California, Oregon, Idaho, and parts of the west and north as far as Alaska. On the coast the eclipse occurs in the morning about 10 A. M. by Pacific time.

Princeton University Observatory

### The New Port of Cayton

ADRIAN-AREA port has recently been laid out at Col. Ambo, Cayton, and it is to be ranked among the great ports of the world. The work started in 1860, and the area included in the proposed port is no less than 985 acres, which is somewhat more than for the port of Dover. A vast area had to be filled in so as to obtain ground for erecting the stonebreakers, quays, repair basins and coal docks. The jetty which protects the port is an almost continuous wall, representing a total of 5 miles length. Good provision for the future is seen in the great size of the repair basin, this having about 700 feet length. The port has a depth corresponding to that of the House Canal, but it is planned to deepen it to 36 feet upon three quarters of the area. As the work, it is counted that the work involved an expense of \$10,000,000, which is not high considering the scope of the enterprise. The present tonnage of the Colambo port is 10,000,000 tons.

NIGHT SKY APRIL AND MAY

light received from the stars of the cluster would be fairly comparable to our moonlight—at least to that of the half moon. Now the light even of a half moon illuminates our sky so brightly that it is quite impossible to photograph faint nebulae like those in the Pleiades. The moonlight simply drowns them out.

The hypothesis that the nebulae of the Pleiades shine by reflection demands therefore only that their reflecting power shall be considerably less than that of the clear air of the Earth's atmosphere. As these nebulae are probably hundreds or thousands of millions of miles in thickness, a very small quantity of material per cubic mile would account for all the phenomena.

The writer may add that still one more confirmation of this theory can be found in the observations of more than one astronomer, which show that the brighter stars of the Pleiades are distinctly yellower than the general run of stars of similar spectral type. Now a cloud of sufficiently fine particles exerts more absorption on blue light passing through it than it does on red light. This is the case, for example, with the color which has passed through our atmosphere, as the color of the setting sun bears ample witness. The light from the Pleiades has to pass through the nebulae lying between us and them, and, if this is fine-grained, it will tend to explain the relatively yellow color of the light which reaches us.

### The Haze.

Our map shows how the skies appear to an observer who looks up at them at the hour indicated below for, for example, 11 P. M. on April 7th. At this hour the Pleiades have set (though two hours earlier they are

# "Standardizing" Highway Construction

## A Plea for Rational Road Building

By Charles E. Foote

**D**URING the last half dozen years, in which highway building has progressed from the commonplace to the scientific stage, much has been achieved about establishing "standards" of construction. Leading civil engineers have written books and delivered scientific addresses before learned societies with a view to the education of those whose business it is to build roads, that they may be able to follow "standards" and to construct first-class highways.

On a six mile stretch of a New York State highway, now under construction, the specifications call for a six inch lower course of field stone, its stone to be more than eight inches in its largest dimension, and the stone to be broken with a sledge until it will roll evenly to a firm mass with a ten ton roller. This foundation course is placed on a thoroughly rolled subgrade. On top of the six inch course of field stone is placed three inches of surfacing material, consisting of broken stone with a bituminous binder.

For the most part of the stretch that type of road will, or ought to, last for years, permanently, if kept properly surfaced. The subgrade is sand and gravel and neither heaves with frost nor breaks in a thaw. The foundation course will settle into the gravelly sand and become as solid as the earth itself. And that kind of soil drains itself.

But at frequent intervals there jut out from the adjacent hills projections of different formations. One may be of hardpan, another of clay, still another of alluvial deposits, and some ledge of loose rock, probably sand disintegrated limestone. These jutting may be anywhere from fifty to five hundred feet wide where they cross the right of way. Sometimes on account of the narrowness of the valley or the position of the river close to the hill, it is necessary to excavate the hillside, possibly building a retaining wall to establish such a roadway as is required under the New York law, with fifteen feet of metalting and four and a half feet of shoulder and a three-foot ditch on each side.

While a New York road is taken as an illustration, because of the vast amount of construction under way at the present time, the same principle prevails in nearly every other State where road building is going on. New York has no monopoly of the idea of "standardization" in making roads.

Why does it not occur to the engineers who make the cross-sections and prepare the plans, to except from the general foundation plan those stretches which require different treatment? The veteran tyro in the road building business should know that the standard, as applied to the sand and gravel subgrade, will not be successful when applied to other soils. There must be carefully studied systems of underdrainage, to lower the level of the bench water to a point below the frost line, or such drainage, to prevent seepage of moisture into the road foundation, or such other treatment as the conditions may require, even if the stretch of road, be not more than two rods in length. Besides, under any such conditions the field stone foundation course should give place to a solid course of evenly broken stone, rolled down, sanded or filled with stone dust, crushed, and rolled some more, so as to make a foundation worthy a good road.

The one thing that may be standardized is the surface. Under present conditions of traffic the standards of to-day are likely to be obsolete to-morrow, even as the waterbound macadam road, standard for a century or more, has virtually passed out of consideration in new construction.

A road in Madison County, Tennessee. A two-horse team has difficulty in hauling one bale (500 pounds) of cotton. Before improvement

The same road in Madison County, Tennessee. Two horses easily draw twelve bales (6,000 pounds) of cotton. After improvement

Excavating for a side-hill road in New York. On this subgrade will be placed a foundation of six inches of field stone, with a three-inch surface of broken stone with bituminous binder

An Illinois road constructed with a surface of tar macadam.

About the only materials available for road surfacing under present conditions are vitrified brick broken stone with a binder of bitumen of some sort and Portland cement concrete. By reason of the limited deposits of clay which will make good road brick, and the expense of freights the use of vitrified brick is confined to limited areas. Wherever it can be used economically brick makes a most excellent road surface. It is durable, smooth and when properly laid durable. It costs, according to the figures prepared by the National Vitrified Brick Manufacturers Association, approximately one thousand dollars per mile per foot of width, where the expense of grading is normal and the freight not excessive. This cost includes the grade and a five-inch concrete foundation.

Different surfaces made of broken stone and bituminous material are as plentiful as are makers of surfacing specifications. Numerous preparations and variations to the collection. Most of them put out, and otherwise, make a wide range of roads within the limits of their available bits.

Concrete of Portland cement with sand and other broken stone or carefully selected gravel is a material preparation is attracting much attention. Wayne County, Michigan has put down a large mileage of concrete roads during the past four years, and the officials express the opinion as entirely pleased and satisfied with the results. Recently a plan of putting on the concrete a surfacing, or mat, of bituminous material mixed with coarse sand or fine gravel has been adopted. This method has become sufficiently recognized so that it has been adopted for a large portion of the California State Highway system.

But these are merely the surfacings. The roadbed itself is the road. The surface can be repaired and replaced when ever necessary as part of the upkeep. It can be standardized today and the standard readily changed to-morrow if found necessary.

In the same general ratio that the soil climate etc. must be standardized to enable a standard foundation to be made must the traffic be standardized to permit surfacing standards to be established. Otherwise all standards must fail.

Ten years ago there were approximately 50,000 automobiles in the United States. Today according to the estimates of the manufacturers there are about one million. Then there were no motor trucks to speak of. Now trucks carrying weights of six or eight or even ten tons are not uncommon.

Ten years ago the horse-drawn traffic on our main roads was almost practically, by what a two-horse team could pull over the worst places. A ton was considered a big load. Over the improved roads two or three tons are not uncommon. Besides the light or pleasure driving travel with horses has been multiplied many fold by reason of improvements in the roads.

Therefore while standards may be made for road surfacings which will meet present travel conditions, what certainty is there that the same standards will be available ten years, five years, or even one year hence? With the tremendous increase in the roadway at least twenty five times greater or than they were ten years ago what right have we to assume that ten years hence, other by changes and development in vehicular construction, or some in application of power, or the augmentation of traffic in some other direction the stresses placed on the highways will not be twenty five times greater than they are now?

## Inventions New and Interesting

Simple Patent Law. Patent Office News. Notes on Trademarks

### Quick-action Bench Vice

**PATENTED** in the accompanying engraving is a quick-action vice which differs from the ordinary in the fact that it contains no screw, teeth or springs. Instead the locking of the jaws is effected by means of tapering surfaces. An adjustment of the jaws is accomplished instantly by simply moving a collar forward which carries the riding jaw with it. The work is first held between the jaws with one hand and the collar is moved forward until the jaws close upon the object after which the jaws are tightened upon the work by a quarter of a turn of the screw. A quarter revolution is all that is necessary whether the jaws be open an half inch or ten inches. The screw consists of a stub threaded into the end of the bar on which the movable jaw is supported. The shoulder of the screw head extends into the revolving lip of the stationary jaw, so that when the screw is turned in the opposite direction it will bear against this lip and force the jaws open. The thumb screw shown in the engraving, on the side of the collar is simply a means to prevent the collar from changing its position until it is necessary to open or close the jaws further. The thumb screw is threaded through the side of the collar and extends into the recess in the side of the movable jaw. The supporting bar on which the movable jaw is carried is secured to the tail end of the fixed jaw, and is provided with sufficient hushwise movement to enable the screw to tighten the jaws upon the work.

### New Railway Mail Exchanging Apparatus

**THE** device here illustrated for the exchange of mail from moving trains was recently installed on the coast Division, California, of the Southern Pacific Company, for twenty stations north, commencing with Durkin. The apparatus is the invention of a former postmaster at Los, Idaho, who had his attention called years ago to the dangers of throwing out mailbags from freely moving trains. The problem was to absorb the shock of the blow which might reach 10 to 20 foot tons on the arm of the standard alongside the truck. This he has succeeded in doing with a horn like revolving arm curved to a diameter of about nine feet. The operation is as follows:

On the standard erected at the depot are two curved horns overlapping each other at the point nearest to the railroad track with a delivery arm extending from the standard toward the track, below the horns. On the delivery arm of the standard is hung a ring to which a mail bag is attached. On the car is a truck running along the roof with a delivery arm on wheels. The mail clerk in the car hangs the bag to a ring upon this delivery arm. The arm is attached by a chain to a catcher hook which is placed on the outside of the forward end of the door. The action of pushing out a delivery arm along the track places the catcher hook in position and the car in position over the top of the door spring. As the train approaches the standard, the hook on the car passes through the ring, which is hung on the delivery arm at the standard, and the horn which is pointed toward the direction from which the car is coming, passes through the ring which is suspended from the car outside the door of the car. The hook on the car detaches the ring from the standard. This ring, with the bag attached, passes along the hook and is deposited on the floor in the side of the car. The horn detaches the ring from the standard to the back where it stops. This action of the horn disengages a catch above the door of the car releasing the delivery arm which automatically returns into the car. As the bag swings around the horn, the horns themselves are

turned up and remain at an angle of about forty five degrees, thus making the required clearance along the track. The mailman at the depot then detaches his ring from the horn and takes away the bag.

This device was first tested at Belle Vernon, California on the San Pedro Division of the Northern Pacific Company, some two years ago, and experiments of

Quick-action bench vice.

an exhaustive nature were made. In the experiments exchanges were made with bags that were practically empty, as well as with a number of large at a time, weighing altogether from 100 to 250 pounds. These were delivered to the standard at speeds of from five miles an hour to between 55 and 60. At such exchange bags were taken from the standard into the car as well.

In order to demonstrate the efficiency of this mail exchanging apparatus a postboard crate of eggs was placed in a mailbag together with about fifteen pounds of other mail matter. The eggs were delivered from a train moving at the rate of 50 miles an hour, and on the return journey of the train an hour or two later,

Exchanging at forty miles per hour with a 34-inch car door

Hanging the mail bag on the crane.

Mail bag caught by the crane

the same bag was picked up again from the standard while the train was moving at 50 miles an hour. Whether any of the eggs were broken was not ascertained. However, we are assured that enough came through unharmed to provide a setting for a hen which hatched out a number of chickens.

### Inventors and Inventions

**PUBLICATIONS** of all kinds relating to improvements invariably recognize and praise the efforts of inventors. A government bulletin issued years ago is quoted as saying: "The discoverer of new products of value in the arts and the inventor of new processes or improved machines, aside to the public wealth, and his right to the product of his brain is now recognized by the laws of all civilized nations." This is the present day view of it, but it was the aim of England in colonial days, as said by McCulloch in his "Commercial Dictionary," to discourage all attempts to manufacture in the colonies such articles as could be provided for them by England. Of course the purpose of this was to increase the dependence of the colonies. Ben nice Platt of Connecticut, probably the best posted legislator as to inventions and patents this country has ever known, said on the floor of the Senate that the passage of the act of 1830 creating the Patent Office marked to him said the most important epoch in the history of our development. He also said it is only when the brain evolves and the cunning hand fashions labor-saving machinery that a nation begins to thrive with new energy and life and expands with a new growth. At one time a special commissioner was sent here by a foreign nation to gather data in regard to our patent system and in response to a question as to why his people desired a patent system he is related, said it was asked: "What is it that makes the United States such a great nation? And we investigated and we found it was patents, and we will have patents."

Senator Platt is for, referred to also said it is interesting in view of propositions from some quarters to increase the Patent Office fees, "A tax upon inventors which provides more than enough to pay the current expenses of the office is simply shameful. It is a tax upon knowledge, a tax on invention, a tax which in itself is an inglorious and abominable as a tax upon authors or scientists would be."

That distinguished South mer Hon John Goode, in a public address, said that inventors "had contributed more to the welfare of their fellows in that period (referring to the last fifty years) than Alexander, Caesar or Napoleon, and their names would survive when those of the great conquerors have passed into oblivion. In future years the names of great soldiers will shine but dimly beside the names of Fulton, Morse and Howe."

The late Senator Daniel of Virginia once said, "The inventor has redeemed us from the curse of poverty, dispelled the mysteries of humber and destroyed the monopoly of knowledge. This senator also said, "The benefits of old acquiesced."

### Guard for Overhead Trolley Wires

**IN** order to prevent the kind of a broken, live footwire of an overhead trolley system from falling to the ground or from dangling in dangerous proximity to persons or animals, an inventor has devised a guard, consisting of swinging lapped fingers that constitute an emergency supports for the feed wire. The fingers are suspended under the feed wire at suitable intervals, and the lapped fingers are held in position by springs so that they will move apart and permit the passage of the trolley pole. Patented No. 1,048,088 has been granted on this device.

Every motorist must

Every motorist must face the above question.

At the end of the season the value of your car will depend almost wholly upon the condition of your motor.

**That will depend mainly on the lubricating oil you have used.**

Motor-wear is not accidental. It results from friction.

*Excessive friction is bound to follow the use of an oil whose "body" is unsuited to your feed system, or whose lubricating qualities cannot properly withstand the demands of service.*

Common results are:

- (1) Undue loss of power
- (2) Unnecessary repair troubles
- (3) An excess consumption of fuel.
- (4) An excess consumption of lubricating oil

To avoid these losses, your motor must be supplied with

- (1) An oil that will retain

efficient lubricating qualities  
*under the heat of service*

- (3) Oil of a "body" that will properly feed to the various friction points.

## Motors differ

No short-cut method can determine the oil that best meets your feed requirements.

The construction of your motor *must* be analyzed and carefully considered

The piston clearance must be known, the fit of the piston-rings into their recesses, the length of the crank shaft and connecting-rod bearing, the feed-system, the length of the vacuum period while intake and exhaust valves are both closed.

We have undertaken this serious problem with the thoroughness that has established our standing in the general lubricating field.

To arrive at correct automobile lubrication we have done what *must* be done. Every year we carefully analyze the motor of each make of automobile.

Based on this motor-analysis, and on practical experience, we specify in a lubricating chart (printed in part on this page) the grade of Gargoyle Mobiloil best suited to your motor.

The superior efficiency of the oils specified has been thoroughly proven by practical tests. In sheer lubricating quality, we can safely say that they stand alone.

So far as correct lubrication can assure it, the grade of Gargoyle Mobiloil specified for your car assures

- (1) The greatest horsepower efficiency
- (2) The smoothest operation
- (3) The fewest repair troubles.
- (4) The lowest operating cost per mile
- (5) The longest life to your motor
- (6) The greatest second-hand value

Throughout the world you will find that the authoritative leadership of the Vacuum Oil Company in matters of lubrication is unquestioned.

The lubricating chart on this page represents our professional advice.

*If you use an oil of less correct "body" or of lower lubricating efficiency than that specified, your motor faces unnecessary friction and ultimate serious damage.*

In buying Gargoyle Mobil-oil from dealers it is safest to purchase a full barrel, half-barrel, or a sealed five-gallon or one-gallon can.

See that the proper name and the red Gargoyle, which is our mark of manufacture, appear on the container.

A booklet, containing our complete lubricating chart and points on lubrication, will be mailed to you on request.

The various grades of Gargoyle Mobiloil, refined and filtered to remove free carbon are

**Gargoyle Mobiloil "A"**  
**Gargoyle Mobiloil "B"**  
**Gargoyle Mobiloil "D"**  
**Gargoyle Mobiloil "E"**  
**Gargoyle Mobiloil "Arctic"**

They can be secured from all reliable garages, auto-supply stores and others who supply lubricants.

# A guide to correct Automobile lubrication

**Explanation:** In the schedule, the letter opposite the car indicates the grade of Gargoyle Mobiloil that should be used. For example, "A" means "Gargoyle Mobiloil A." "Arc." means "Gargoyle Mobiloil Arctic." For all electric vehicles use Gargoyle Mobiloil A. The recommendations cover both pleasure and commercial vehicles unless otherwise noted.

*A grade for each type of motor*

[illegible]

A successful electric starter is more than just a motor and a storage battery—

Get that fact firmly fixed in your mind.

The efficiency of an electric cranking and lighting device depends upon its ability to maintain an even and constant charge in the battery under all sorts of operating conditions.

It is a comparatively simple matter to hitch an electric motor to a gasoline engine and start it with power drawn from a fully charged battery—

It is equally simple to combine with the motor a generator that will force electricity back into the battery and recharge it—under certain conditions—

But—to so regulate the flow of current from the generator to the battery as to maintain approximately a full charge at all times—and never permit an overcharge is a feat that only the highest type of electrical and automobile engineering have been able to accomplish.

If it had been an easy feat the Delco System would have been given to the public two years before it was.

# The Delco System

## Electric Cranking Lighting-Ignition

was a finished product before the first Delco equipped car appeared—

The experimental work of years was back of it—

Its makers knew that it would do its work not only in show room demonstration, but in day after day and month after month of hard service.

Twelve thousand Delco equipped cars were sold last year—

Over forty thousand are being produced this year—

The superior efficiency of the system has been complexly and emphatically demonstrated.

Automobile manufacturers and owners have learned that Delco equipment once put on a car is there to stay—and to give constant, never-failing service—

It cannot be jolted or jarred to pieces.

There is nothing delicate or breakable about it.

It is not complicated or heavy—

And—most important of all—no matter whether the car be driven much or little, fast or slow, there is always an ample supply of current in the battery—and *never* an overcharge—

Do you wonder that the great Delco factories at Dayton and Chicago are rushed to their fullest capacity—

And that Delco equipped cars are already at a premium?

**It is a significant fact that every car carrying Delco Equipment for 1913 is already oversold.**

*If you are interested in electrical starting, lighting and ignition systems write for Delco book—*

**The Dayton Engineering Laboratories Company, Dayton, Ohio**

# Exact Science Applied to HOUSE BUILDING

Can you think of any particular or notable advancement made in the methods of building ordinary houses within the past hundred years or so? Rather astonishing, don't you think? Of course we have refinements in design and improvements in constructional details, but the average architect, the average contractor and the average carpenter are still using the ordinary, usual, average methods, but not the methods of handling material and time.

## Why lower costs by eliminating waste in handling labor and material

"I low much does this waste amount to?" you ask. On a one thousand dollar house it approximates \$126 on the material and \$138 on the labor, cubitree per cent on the material and forty-six per cent on the labor. Those figures represent 26.4 per cent waste on the cost of the complete house. Two hundred sixty-four dollars waste on a one thousand dollar house! Will you ask us to prove this astonishing fact? You have heard of the wonderful cost-reducing results of "scientific management," efficiency, etc., in business. These house building means put one thing—cutting out waste—in labor and material. The house you build a mean just two cents more in labor and material. The Aladdin System reduces the eighteen-per-cent material waste to two per cent. It wipes out completely the forty-six-per-cent-labor waste. In no other way does the Aladdin house differ from the ordinary well designed, well built house. The Aladdin catalog illustrates this graphically.

# ALADDIN READ- CUT HOUSES

are built by the same system as the modern sky-scrapers office building

## What you get with each Aladdin House

Aladdin houses are manufactured and shipped from four greater of lumber producing sections of the country. High prices are cut through the use of material purchased from the original producer. The price on each house includes material guaranteed to be sufficient for the completion of the house as follows: all framing lumber cut to fit, shingles cut to fit, siding cut to fit, flooring cut to fit outside and inside finish, windows, frames, camp, stairways, girds, hardware, latches, rods, pins and varnish for the outside and inside, plaster board or lath and plaster for all rooms, with complete instructions and illustrations for erection.

# THE SAFE-CABINET

Shown in this illustration

was next to the window marked with the arrow in the Union Trust Company's fireproof safe in Cincinnati, when the office in that great building were devastated by the flames which swept over the Gibbon street side adjoining building in the fire of December 10, 1912.

THOUGH the destruction of the contents of these offices was almost complete, this SAFE-CABINET, standing in the very heart of the configuration, preserved its contents unscathed.

THE SAFE-CABINET, 1815 Model, is approved by the National Fire Protection Association. It is made of heavy steel and is very strong. It is very easy to use and is very attractive. It is a must for every home.

THE SAFE-CABINET CO., Dept. 7-4, Buffalo, N.Y.

# Notes and Queries

Kindly keep your queries on separate sheets of paper with corresponding short notes, and send them to the Editor of the Scientific American, 233 Broadway, New York, N.Y. The Editor will be glad to answer them, and will be glad to publish them, and will be glad to publish them, and will be glad to publish them.

(12702) D G S asks: Will you please give information as to the weight of such or globe? Is it or is it not heavier now than when first completed? A. The earth is heavier now it was at the first of the width of the moon which sinks it from time to time. Some of them are very small and others weigh considerable. The one brought from Greenland by Admiral Pelly weighs some forty tons. It is now in the American Museum in New York City. The earth, however, is so heavy that some additions to it do not affect it to any appreciable degree. A. The moon is the reservoir of all the rivers and small streams and it is salt water. In returning back to the hands of all the oceans, when it does it not before the salt water with it. A. The salt of the ocean is not evaporated, but remains in the ocean water. The water which evaporates and goes back to clouds to be dropped as rain on the mountains is fresh water only. You can prove this by drinking some water at sea and letting it stand in the open air. As the water evaporates, the water tastes stronger of salt than the sea water. The crystals of salt appear in the dish. Finally when the water has all disappeared you will find at the bottom in crystals on the dish.

(12703) J P asks: In a lecture on "The Great Pyramid of Egypt" it was stated that it was built true to the meridian in the day. May I ask your Notes and Queries? I. A staff in earth's axis which direction rate and cause? The change of the axis which the lecture makes of does not refer to a change of the axis in the earth itself which would change the latitude of things but to a change of the direction of the axis in space which causes a precession of the axis of the earth. This is called a spinning top. This motion is called the precession of the equinoxes, and is explained in all astronomical works. A Manual of Astronomy page 22.30 postpaid. 5 New south does the pyramid vary from the present meridian and the time this variation would require? At the time of the building of the Great Pyramid the brightest star in Draco was the North Pole star and the meridian position of that pyramid was directed toward that star. It is now many degrees from it. It will require 26,000 years for one revolution of the axis of the earth around the pole of the ecliptic. Then the same star will be the pole star again. 3. Are the lines, proportions, laying of stones in the Great Pyramid more accurate than modern engineering work? We do not suppose that any modern mechanical skill was possessed by the builders of the pyramid than engineers possess nowadays. They did not work with a compass. The pyramid is well placed north and south east and west. There are those who believe that the pyramid cut each in its measures and weights, the size of the basket and wire measures, the length of the year the precession of the equinoxes, and much besides. See Placid Smyth's great work in two volumes on "Our Inheritance in the Great Pyramid."

(12704) P A R. writes: In your issue of February 17, P. 8, mentioned the presence of small atoms appearing in a storm of snow. Now, in your January issue (p. 17) there is a short notice of M. Thales's explanation of how large bubbles are carried by winds. Might we not adopt his theory to the case in hand? Might we not say with him that we must accept the idea of flexible air around the storm clouds and make it? I have witnessed the presence after a heavy rain of at least four little mounds in Chicago's backyards, whose being as all could be explained only by the supposition that they were carried there by the rain and wind of an envelope of air or water vapor? The density of the transported mass of combined solid and fluid matter would then be that of the wind, and would be much lighter with respect to its volume. This envelope would be borne by the wind much like a soft cloud sailing through the air. A. We have no theory to defend as to the manner in which these particles were carried to where they were found. Probably they came from the earth underneath. But it is possible in some of the cases of small atoms appearing in a storm of snow or a storm has passed over that they have been taken up by the wind and carried a long distance. The reference you make to the *Scientific American* of January 4th, 1916, page 17, is in point.

W. H. H. writes: "Electromagnetism" page 100 gives the velocities which will take up arcs of various weights. Some of them are heavier than others, and the wind velocities are lower than are frequently encountered. It is clearly possible that the storm which you refer to may be due to something which is not a storm, but a heavy horizontal. Such a storm could easily be a middle of water, mud, etc., and even then it is not to drop them easily under their own weight. It is possible, but not so unlikely that this storm should only be brought when the relative humidity is. One circumstance has taken us seriously to take in this matter, but we are not ready to yield the possibility of some cause in some instance.

 CLEVELAND

Five passenger Model Montclair  
A high powered "Light Six" Lozier \$3250

**On the busiest streets in the world**  
just as on the great touring highways—at home and abroad—you find, in fast increasing numbers, the Lozier.

Lozier—admittedly the predominant Six—is now in its sixth successful season. These years of six-cylinder experience, and six-cylinder *supremacy*, are a guarantee of highest grade construction. You can find Lozier quality in all its phases only in a Lozier car, and most men who know automobiles *best* are not *satisfied* with *less*.

With two great models—the famous Big Six and the new Light Six, "a self-seller"—Lozier achieves sensational success this year. Our ambition is to be able to build enough Loziers to meet the Lozier demand.

### "LIGHT SIX" \$3250

**A**UTOMOBILE authorities, writers in technical journals, owners of high-grade cars, and the trade, all declare the *surprise* and feature of the year has been the production of a Lozier—and a *new* Lozier—at a medium price.

When we announced this lighter model of the only American built car which for eight years has commanded still commands a price of \$5,000 that announcement instantly became the talk of the industry.

But it remained for the car itself to create the real wonderment. Here, truly, was a Lozier for only \$3250. A Lozier in every line and every part—not quite so large as that marvelous Big Lozier which for years had commanded the respect of the public and the industry alike, but high-powered—and a Lozier through and through, a Lozier in its strength and safety and comfort and fineness of workmanship and distinctive beauty.

Our dealers, themselves, named the LIGHT SIX "a self-seller." And the three months now have proved that it is. The demand for this Lozier at *less* than \$5000 is a factory capacity demand.

You will marvel at the *completeness* of this car. A more perfectly equipped car has never been produced. Everything you could *ask* for is on the car. Electric self-starter—electric lighting—Warner speedometer—windshield built into body, adjustable for ventilation and rain vision—tilt motor top, top cover, curtains quickly raised—everything that makes a car really complete. And remember, the Lozier "LIGHT SIX" has left side drive, center control, a "stream line" body and many other advanced features, without which no high grade car should deserve your serious consideration.

Lozier "Light Six" Touring Model and Roadster \$3250  
Coupé \$3850; Limousine \$4450

### "BIG SIX" \$5000

**A**LL PRESENT indications point to a record sale of Lozier Big Sixes this season. A never before the wealth and discriminating motor car purchasers expressed their convictions as clearly in favor of the Lozier. Their attitude is well founded.

The Lozier has *proved* itself the superior Six. Years of service in owner's hands and years of grueling tests on every principal American speed way have left no room for doubt of Lozier efficiency.

And, added to the proof of Lozier six-cylinder supremacy, new advanced features of construction make the Big Lozier stand out in the foreground of all high grade cars.

The new automatic-level riding system gives high oil level at high speeds, low level at low speeds, a smokeless exhaust at all speeds, an efficiency beyond all previous achievement.

The motor is the most powerful ever built into a Lozier car, but vibrationless and silent with the widest known range of speed.

Triple ignition provides a medium for securing *triumphantly* in exact power *when you want it*. Left side drive and convenient center control, as featured in the Lozier, are rapidly becoming standard construction on all automobiles.

Fifty-eight sets of ball-bearings—more than used in any other car in the world—explains, in part, the unequalled Lozier power, mastery of the longest and steepest hills, Lozier motor flexibility and Lozier long-life.

Touring Model and Roadster \$5000  
Limousine and Landaulet \$6500

**Among the prosperous manufacturers of low-priced cars and among the heads of the great accessory manufacturing concerns—men who really are in position to judge automobile values accurately and men who, for their own sake, want to drive the best—Lozier is the distinct favorite. Eight executive heads of one low-price car company, alone, have purchased and drive Loziers. THESE MEN KNOW**

**LOZIER MOTOR COMPANY, 4504 Mack Avenue, DETROIT, MICH.**

Factory Branches in New York, Chicago, Philadelphia, Boston and San Francisco. Dealers in all principal cities.

# Harnessing Nature—Electrically

Human ingenuity assisted by the ability of large manufacturing companies to produce practical and economical machines is conquering the powers of nature more completely every year.

The product of the coal mines is transformed into electric power in all parts of the country by large steam turbines built by the General Electric Company. Gasoline is used economically in isolated localities by the G. E. gasoline engine generator, and the G-E Gas Electric Motor car is giving excellent service on rural steam lines.

Fig. 2. A. F. H. H. H. H.

Fig. 3. A. F. H. H. H. H.

Fig. 4. A. F. H. H. H. H.

As new circumstances arise these same facilities will be devoted as heretofore to the development of practical and reliable apparatus for the harnessing of nature electrically to the service of man.

Complete information on any of the equipments mentioned above or in any problem of controlling electric power will be furnished on request from our nearest office.

Enormous generators connected to water turbines are successfully harnessing the water powers and pouring cheap electric power into the large transmission distribution systems which make possible the present wide use of electricity.

The future may see nature harnessed in new ways—from the sun, wind, or sea—who knows? But one thing is generally accepted that new methods will be combined in some way with electricity—for the increasing economies of transmission, the convenience of application in the factory, and the increasing use of Edison Mazda lamps in the home—all point to the continued use of electricity long after the coal resources of the country have been depleted. With this in mind it is interesting to note how electricity has been harnessed by the General Electric Company's apparatus.

## The Controlling Reins of Nature's Harness

In steam turbine and water wheel stations the control is so perfect that one man can sit at a desk or bench—in front of a switchboard at a distance from the machinery, and by means of small levers can start, stop, or regulate the power at will. This power transmitted to cities and towns is again controlled by smaller switchboards which distribute the current in factories, railways, or homes as required.

In the modern factory today men no longer have to pull levers or shift belts for the G. E. push button method of control enables the operator to start the motor by simply pressing the button thereby giving him more time and energy for his work. By simply pushing a button also the engineer in the basement of a modern city building can regulate the speed of the ventilating fan on the top floor or turn on the electric sign on the roof.

The large electric motors for the Panama Canal locks will operate from a distance by small G. E. control switches. Many large enterprises, such as the Cadillac Aqueduct, employ automatic devices to keep water levels constant without attention.

In railway service, the General Electric Company's platform type of control is well known. For heavy train service Sprague G. E. type M control provides for the addition or dropping of cars for automatic acceleration when required and for the stopping of the train automatically when the trainmaster's hand leaves the handle which controls the train.

In the home, a press on the button, turns the power of electricity into light, heat or power by means of devices which are becoming universal throughout the country.

The extensive resources and manufacturing facilities of the General Electric Company have assisted in the work of harnessing nature in the manner briefly outlined above.

# Electricity

**Heavy Consumption in Electric Welding.**—In a discussion in a recent paper on "Resistance Welding" the remarkably small amount of energy required to weld iron wire was brought out. A weld between a pair of 5/32-inch rods takes 30 watt-minutes, which means that 3,000 watts of this kind could be made with the expenditure of one kilowatt-hour of electrical energy. However, the amount of energy rapidly increases with the diameter of the rods welded, 5/16-inch rods requiring 2,000 ampere, about nine times as much energy as rods one half that diameter. This increase is due to the increased contact area and also to the rapid cooling through the jaws holding the rods.

**The Telephone Equipment of Capt. Scott's Expedition.**—An English paper gives an interesting account of the telephone service that was provided to connect five stations of the British Antarctic Expedition, that is, the living quarters with the four instrument and observing stations. In order to save weight, a matter of such prime importance in the transportation of supplies by polar explorers, the line wire employed was bare hard drawn aluminum. About 75 miles of this wire was carried and the lines connecting the stations were metallic circuits of this wire here laid out six feet apart on the dry snow which, as is well known, is an excellent insulator. The low temperature precluded the employment of industrial batteries at the stations, and a 24-volt "common battery" was used.

**Working Cables and Land Line Without Re-transmission.**—A new and very simple system of submarine cable working, the "Land Line" system, as the engineer, is announced. By reversing the current for each successive signal, the distinctness of the signals is so increased that the siphon recorder, hitherto the receiving instrument for cables for cable working, has fair to be abandoned. By using a new system of successive dots, for example, are signaled by two currents of opposite polarity. It is stated that the ordinary Morse code can be used, and a land line can be joined up with a cable and a message sent by an ordinary telegraph key. Although the system is simple, the speed of signaling is increased by the new method that the elimination of re-transmission at the junctions of land lines with cables (under certain conditions which will doubtless appear when the invention has been tried) is in itself an important improvement in telegraph engineering.

**A New Electric Tanning Process.**—Invented by the Swedish scientist Dr. A. Groll and employing a practical scale in an English works, is attracting much attention, and it is stated that one of the prominent electrical firms is soon to take it up for commercial use. With this method, the hides are put in special vats along with metal conductors, so as to carry out an electrolytic action, and this will tan the hides in much less time than usual, for instance, six weeks as compared to several months. Leather of better quality is produced in this way, and the method gives a perfect and solid tanning. The details of the method are not as yet made public. Various electrical devices in the shape of regulators and indicators, also safety apparatus for over-current, make the process almost an automatic one, and in the present trial plant at Kildermidmore two persons are not needed to take care of the vats, as by anything going wrong in one of the vats, electric bell or lamp signals give warning at once. The plant keeps running day and night.

**Remote Control of Light and Power Circuits.**—Turning on and off the electric lights connected to a distant service circuit has been a problem that has hitherto been met in three ways, by sending a man to manually switch on the lights in the evening and switch them off again in the morning, by clockwork switching devices set to operate at a pre-determined hour, and by utilizing a prepayment meter to open the circuits when a determined amount of energy shall have been consumed. A new method of remote control of lighting and power circuits, whereby such circuits may be closed at any time from the central station (as for example to cover the emergency of a fire) and varying hours of darkness) has been devised, utilizing a special current superposed on the main lighting current whereby the latter is alternating or direct. The new system is particularly adapted to the control of street lighting circuits. In the application of this method to alternating current service a "apple" or alternating current of higher frequency than the actual frequency of the service current is sent out over the mains for as instant, actuating a local switch-operating mechanism permanently connected to the mains but designed to be sensitive only to the "apple" frequency. In the application to direct current service a condenser included in the relay circuit acts to prevent consumption of energy in the relay except during the moment of passage of the alternating current element which inverts the condenser in operating the relay.

# Science

**Captain Scott's Journal.**—According to the London Times, Lady Scott has telegraphed from New Zealand that her husband's journal is in her possession, "well preserved and complete." The whole will be published shortly in book form, and parts will appear in an English magazine.

**Peary at the International Geographical Congress.**—Rear Admiral Robert E. Peary recently sailed for Naples, on his way to Rome where he is to attend the International Geographical Congress, which opens on April 10th and the meeting of the International Polar Commission which will follow it. Rear Admiral Peary will represent the United States officially.

**The Philatelic Library of the late Lord Crawford,** the most comprehensive collection of books and pamphlets on postage-stamp collecting that has ever been brought together, or is ever likely to be, has become, by his bequest, the property of the British nation, and will doubtless be placed in the British Museum. Mr. Beeson's catalogue of it, recently published, is a large quarto volume of over 450 double-column pages, and its compilation extended over several years.

**The Brilliance of Venus in the evening sky** during the early months of this year has led to the usual crop of wild rumors as to what the "strange light" could be. In England it has been mistaken for a German military aerob, while the newspapers of southeastern Rumania have been reporting nightly visits from an Austrian spy in an aeroplane. It may be recalled that, many years ago, a section of the New York public took the same planet to be an illuminated balloon sent up by Mr. Edison from Montic Park in the course of some mysterious experiments.

**The Term "Gentile"** is applied in Haiti to mysterious acoustic phenomena, probably of subterranean origin, and evidently belonging to the class of sounds known as "hundreds" or "brontides" (see SCIENTIFIC AMERICAN, January 18, 1918, p. 60) reported from various parts of the world. They seem, however, to be much more varied in character than the typical brontides of Italy, Japan, etc. Sometimes they resemble the boom of cannon but again are described as deep rumblings, howlings, a rushing sound of wind, a dull rumble, or a rattling sound of glass over shattered. And so on. They have been known in Haiti from the times of Morisson du St. Mery and the other early historians of the country. St. Martial Ogey, at Port au Prince, has undertaken a systematic study of this phenomenon, and has collected a questionnaire addressed to numerous residents of the island, thus following the example of Van den Broek in Belgium, and Alippi in Italy.

**The Failure of the "Electric Niagara"** or overgrown lightning-rod, recently erected in several parts of France in the belief that they would avert hailstorms by drawing the electricity from the clouds, is reported in emphatic terms by a writer in the *Journal of the National Society of Horticulture of France*, M. A. Lafont, who, however, advocates the equally illusory expedient of "hail-shooting." Several severe hailstorms occurred in Paris shortly after a great "Niagara" had been installed on the Eiffel Tower (see SCIENTIFIC AMERICAN, June 26th, 1912, p. 548). On June 19th, 1912 hail fell in great quantities at the very foot of the tower and over an extensive area of the suburbs. The hail season, which began some eleven years ago in the department of Vienne, and it has been repeatedly claimed that they have completely exempted that part of France from hailstorms ever since they were installed. This claim was, however, refuted in 1911, when M. Turpin, an expert on hail, without foundation. Fifty-two "Niasaras" had been erected in various parts of France up to last October.

**Scientific Results of the War in the Balkans.**—In the *Bulletin of the American Geographical Society* Leon Dominikan calls attention to the rich field of the study between Turkey and the Balkans, by reason of Ottoman control of a large section of the Balkan peninsula. Nearly every square mile of the territory in question needs mapping, and it is besides a practically virgin field for geological, ethnological and historical study. To judge from the reports of the military Cartographical Institute, at Sofia, we may expect excellent map-work in whatever territory that country may acquire from Turkey. Whatever may be the motive of the study between Turkey and the Balkans, it is notorious that science and exploration do not flourish under the Crescent, whereas the other Balkan states are at least in sympathy with modern ideas in these fields, so that the study of the Balkans is a most fortunate case from a scientific standpoint. Just to mention one point of contrast, Bulgaria, Serbia and Greece all possess official meteorological services, with networks of stations whose observations furnish the material for the scientific study of those countries. Turkey has nothing of the sort, and what little information we have of her climate has not been gathered by Turkey.

# Aeronautics

**The International Commission for Scientific Aeronautics** (which ought to be called the International Aerological Commission) will hold its next international meeting in London, in 1915.

**Bomb for Use with Aeroplanes.**—Hiram Stevens Maxim, of London, England, assignor to Vickers, Ltd., Westminster, England, has secured a patent, No. 1,052,000, for a bomb for use with aeroplanes, the bomb has a charge of high explosive, a detonating charge and a pole which is adapted to move laterally to the bomb when the latter is liberated and to bring the detonating charge into position to fire the main charge. The detonating charge of the pole strikes the ground, an object or a target.

**Aerological Station in the Heart of Africa.**—The German government which has already done so much more than any other government in the world for up-to-date research, is now planning a permanent aerological station on Victoria Nyanza. It was over this lake, in the year 1908 that a German expedition sent up the first sounding-balloon that ever reached the isothermal layer in equatorial regions, and observed at an altitude of 12 miles, the lowest temperature ever recorded in the atmosphere, viz., 110 degrees below zero Fahrenheit.

**An Erroneous "Record" in Ballooning.**—In August, 1909 much confusion was aroused by the statement published in the *London Times* that the new record for altitude, Lieut. Mina and Signor Pasovovic, had secured from Turin in the balloon "Albatross" to an altitude of 38,715 feet exceeding by more than 3,000 feet the altitude attained in the famous ascent of Voisard and during that of the *Zeppelin*. A note published in *Aviation* this year to a note published in *Aviation* this year was something very like a *canard*, as the aeronauts had no proper means of measuring their height and have since published a revised estimate reducing the reported altitude to 33,810 feet.

**Aeronaustical Surveys.**—The idea of carrying out surveys in the Sahara and elsewhere with the aid of aeroplanes and aeroballoon has often been suggested, and it seems likely that many blanks on our maps, where primary survey is impossible, will be filled in by the latter, will ultimately be filled up in this manner. A German writer calls attention to the fact that the first demonstration of the feasibility of such undertakings was furnished by the Italian military aeroballoon during the recent war. The Turkish aeroballoon, which was used by the city of Tripoli was mapped from overhead. The data thus obtained enabled the general staff to construct a series of charts on a scale of 1:40,000.

**Ruin on Monoplane Wings.**—In a recent number of *Flight* Mr. Griffiths Brown takes the subject of the collapse of monoplane wings. Calling attention to the fact that about a year ago Heliport reported to the French government that monoplane wings were liable to collapse in the air, not only by the breaking of the stays under the wings, but also by the breaking of the supports over the wings, Mr. Brown inquires into the cause of the structural collapse to which monoplane wings are peculiarly liable. Because the wings of monoplane possess little arms from the sides of the frame, he agrees that it is easier to twist the outer ends of the wings than the shoulder portions. "Without changing the path of flight by the machine," Mr. Brown states, the speed of travel may increase and this causes the center of pressure to move forward, tending to turn the wings over forward, owing to the pressure on the front portion decreasing while the pressure increases behind the rear portion. The effect of this change in the center of pressure is a progressive twist from the shoulder of the wings outward, the left wing twisting like a right hand and the right wing twisting like a left hand and so on.

**Aeroplane Trips Between Nice and Monte Carlo.**—The Trans-aeronaut company is organizing a daily service of aeroplanes trips over sea between Nice and Monte Carlo on the Mediterranean coast. Hydro-aeroplanes are to be used, and they will fly along at a short distance off shore during the trip. For greater safety, a motor launch will accompany the flyer although it is now recognized that there is little danger in an over-water trip in a hydro-aeroplane. The apparatus to be the first instance, of the regular use of the hydro-aeroplane, and the results will be watched with interest. The trip from Nice to Monte Carlo costs \$20 and the round trip \$30. A ten-minute flight near the coast costs \$10. Hydro-aeroplanes are to be used, and they will fly along at a short distance off shore during the trip. For greater safety, a motor launch will accompany the flyer although it is now recognized that there is little danger in an over-water trip in a hydro-aeroplane. The apparatus to be the first instance, of the regular use of the hydro-aeroplane, and the results will be watched with interest. The trip from Nice to Monte Carlo costs \$20 and the round trip \$30. A ten-minute flight near the coast costs \$10. Hydro-aeroplanes are to be used, and they will fly along at a short distance off shore during the trip. For greater safety, a motor launch will accompany the flyer although it is now recognized that there is little danger in an over-water trip in a hydro-aeroplane. The apparatus to be the first instance, of the regular use of the hydro-aeroplane, and the results will be watched with interest. The trip from Nice to Monte Carlo costs \$20 and the round trip \$30. A ten-minute flight near the coast costs \$10. Hydro-aeroplanes are to be used, and they will fly along at a short distance off shore during the trip. For greater safety, a motor launch will accompany the flyer although it is now recognized that there is little danger in an over-water trip in a hydro-aeroplane. The apparatus to be the first instance, of the regular use of the hydro-aeroplane, and the results will be watched with interest. The trip from Nice to Monte Carlo costs \$20 and the round trip \$30. A ten-minute flight near the coast costs \$10. Hydro-aeroplanes are to be used, and they will fly along at a short distance off shore during the trip. For greater safety, a motor launch will accompany the flyer although it is now recognized that there is little danger in an over-water trip in a hydro-aeroplane. The scout in the air does not always discover the location of hostile troops.

## Achievements of Military Aircraft

Lessons Taught by the European Maneuvers and by the Tripolitan and Balkan Campaigns

By Major H. Bannerman-Phillips

It is not to be considered in a general way the advantages and disadvantages inherent in aerial as distinct from ordinary reconnaissance on the ground. To begin with, the observer's point of traveling freely in any direction without hindrance, regardless of terrestrial obstacles and of placing himself directly above any object so that his line of sight is at right angles with the earth's surface gives him a considerable advantage. The enemy's dispositions would seem at first sight to be inevitably laid bare to him and this is true, though with certain reservations. The observer, in order to be safe from the fire of troops on the ground, must remain at a fairly high altitude and if in an aeroplane, must travel very swiftly. Therefore his line of observation passes through a number of layers of the atmosphere the state of which affects the possibilities of reconnaissance. Hence his view of terrestrial objects is liable at times to be blurred and indistinct. Secondly, the enemy will be on the lookout for him and in the daytime he can hardly hope to escape observation himself and if he is covered by clouds from view of the enemy the objects he is reconnoitering will also be hidden from him. Now for purposes of military reconnaissance, exactitude of observation is essential; therefore the scout must have a good view. Yet with, under certain weather conditions, a man may be able to find his way about a country and recognize its landmarks, but he may not be able to make exact observations of the enemy's dispositions and may need to correct his information. In any case the aerial observer requires special training and optical instruments so that a scout at the ground level.

### The Difficulties of Reconnoitering in the Air

In observing the dispositions of troops in the field, under normal conditions of the atmosphere and from such a height as to be reasonably (though not completely) safe from terrestrial marksmen, say 1000 feet, the radius of observation from moving aircraft may extend to four or five miles from a point vertically below the observer. Beyond this height, it is common difficulty to distinguish various objects on the ground surface. Troops on the march can be seen and their numbers estimated from the road-queue occupied, and the size of camps and their arrangements can be noted. Artillery in action are an easily distinguishable mark and so are cavalry on the move and transport columns of all kinds. Massed infantry in the open are fairly distinctly seen and peculiarities of uniform may help the observer, but infantry in khaki are difficult to distinguish when in extended or oblique lines, or retiring through scrub or ploughed land and not always clearly seen on grass. Infantry columns halted during a march and sitting or lying down at either side of a road are not easily made out in order to get any idea of trenches, outposts, arrangements, and the methods of occupation of bridges and fords; the observer will have to depend within the danger zone of the fire. Further it is a common error to suppose that everything is clearly visible from aircraft in mid-air. For instance at 1000

Army transport wagons at Mustapha Pasha as they appeared to the air scout.

The battlefield at Mustapha Pasha viewed from an aeroplane.

War trains at Mustapha Pasha railway station, a very busy transport center as it appeared during the war from a military flying machine.

feet up, one cannot get a view into the bottom of a valley, the direction of which crosses the line of sight at a distance of say three miles. If the slope down to the valley is steeper than 9 degrees, motionless troops are hard to see even on flat ground, and the amount of concealment afforded by trees to troops underneath them (or where the trees are lofty, and come between them and the aerial observer, for some considerable distance behind them) is far greater than would be supposed. Movement will often betray the presence of any enemy who would have escaped notice if he had remained motionless, and, as often happened during the Boer war, clouds of dust will betray the movements of troops, especially horsemen, at very long distances. In clear weather bodies of men, such as single squadrons, battalions and batteries, can be seen, when closed up to seven or eight miles with ordinary linealities. Fieldworks, if their color and outline do not blend with the surrounding features of the country, may be seen at four or five miles, but are not readily distinguishable. To tell "dummy" trenches from real ones is difficult, sometimes impossible. Railways which run parallel to the line of vision are readily made out, embankments and cuttings being especially visible, but a railway running at right angles is not always seen unless attention is directed to it by a train in movement or the smoke and steam of a locomotive. Rivers, canals, and water in the form of ponds and lakes stand out clearly and so do bridges, but from considerable heights the smaller details of a landscape are very difficult to make sure of. Top-fields in England with the poles and wires covered by the summer's growth of hops, have been taken for pasture land before now.

### Hiding from the Man in the Air

The airman's greatest difficulties will come in the future when the art of concealment of the movement of troops, and their disguise by various methods, may be expected to reach a high pitch of perfection.

The British army maneuvers in East Anglia in 1911 were remarkable for the success of the reconnoissances effected from aircraft of both the gas-supported and heavier-than-air types, but there was one notorious failure which proved the exception to the rule. The Fourth (Blue) Division succeeded in performing a march from near Cambridge to Mildenhall, about sixteen miles, entirely unseen and unreported by the Red air-seconds, yet these latter were watched by the Blue troops from the ground-level, sitting overhead in various directions. If such an incident were related in the history of a campaign it would seem incredible, but it actually occurred nevertheless. This result was secured by simple expedients—no simple in fact that after the event they were dubbed "perfidious" by at least one military critic, but their success in this case certainly justified their use. In the first place the troops started their march during the night and covered as much ground as possible before day-break. Secondly, during daylight they kept in small detachments and took every advantage of the shelter of the trees, and when halted,

# Harnessing Nature

## Can the Free Energy of Space be Utilized?

By Waldemar Kaempffert

IN A few centuries the world's coal mines will be exhausted. Where shall we derive the energy to turn the wheels of industry? By harnessing nature is the answer. Long before we took stock of our fuel supply and found that we must husband what little we have left, scientific dreamers wondered whether to mine the potential energy stored up in every cubic inch of a natural force, however artificial our means, must seem their power to nevertheless utilize it, is obtained from the sun. But that power is less than it appears and applied only by complicated and costly means, so that it wastes many times more energy than it delivers. Why should it not be possible to tap the free energy of space the energy with which the sun, for example, incessantly bombards us? Can not some chain be devised to transform and make available the apparently limitless supply of energy illustrated in every atom of radium? To answer questions such as these with anything like satisfaction is impossible. Yet they are discussed by the most distinguished physicists of the day, and therefore they acquire a clarity with which they might not otherwise be invested. At the fourth annual meeting of the British Science Guild for example the whole vast subject of harnessing nature was considered and a committee of seventeen was appointed to report upon it. Among the members of this distinguished body were some of the scientific men as Mr. William Ramsay, Hon. R. J. Strutt, Prof. A. B. Lawrence, Sir Charles A. Parsons, Mr. Ignatius Clark, and Mr. H. E. Shaw. The committee has not yet submitted its final report, but it has done enough to show how wonderful are the possibilities of engineering with commodities will no longer be available and along what lines the investigator must work if success is to be attained.

### Water Power

The only natural source of free energy that engineers have thus far successfully utilized is water power. How they have gone to work is so old a story that it need not be retold here. Their task was simple. The crudest kind of wheel would around corners centuries ago. The art of turning the Niagara Falls are merely in progress upon it.

A water fall is a ready-made solar engine, the only commercial solar engine that man has succeeded in utilizing. No machine has ever been devised or ever will be designed that will surpass the water fall in efficiency. The sun pumps the water of ocean, lake and river on mountain tops and the force of gravity draws the water again to its original level. The cycle is endless. Because there are no valves, no shafts, no connecting rods, no pulleys, the efficiency is one hundred per cent. It has been calculated that the total output of these atmospheric deposits amounts to 100,000,000 horsepower. With the advent of electricity and its introduction into industry part at least of this energy is being used, the one example of the successful use of nature's free energy.

### Putting the Sun to Work

But why not go directly to the sun? Its radiation has been measured and expressed in engineering units. In its total incandescence of 1913 Sir J. J. Thomson stated that shining from a clear sky the sun sends to the earth energy at the rate of 7,000 horsepower per acre. Moreover, as the temperature of the sun is at least 6,000 deg. Cent this energy must arrive in a highly available condition, theoretically it ought to be almost wholly convertible into mechanical work. No wonder that the construction of a commercial solar engine has been one of the most fascinating problems that ever engaged the attention of inventors.

As to whether nature's most abundant experiments on record were those of Capt. John F. Johnson, designer of the famous "Monitor". On a rainless strip eight thousand miles long and one mile wide extending almost continuously from Africa into Asia and from South America into the United States, solar heat enough is wasted he figured, to drive 22,000,000 solar engines of one hundred horse-power each nine hours a day.

In endeavoring to utilize a very small part of this tremendous amount of waste energy, Johnson worked productively from 1945 to 1976 and built in that time no less than seven solar engines. He adopted the rather obvious method of concentrating the sun's rays on a boiler when he was driving his engine by steam, and on an air engine when he was driving it by the "hot air" engine. Recently he succeeded in driving about one horse-power for every one hundred square feet of reflecting surface. Finally he came to the con-

clusion that the scheme was impracticable. "The fact is," he frankly admitted, "that although the heat is obtained for nothing, so extensive, costly and complex is the concentration apparatus that solar steam is many times more costly than steam produced by burning coal."

Since Johnson's day other attempts have been made along different lines. Readers of the SCIENTIFIC AMERICAN are familiar with the proposals of Mr. Frank Shuman, Prof. Reginald Fessenden, and Messrs. Will and Ed. Boyce. If because their apparatus has been described in these columns at sufficient length it is unnecessary to dwell upon it again, let us turn to the solar power plants, the "hot box" of de Saussure, Langley and other pioneer solar physicists is employed. In other words, a film of water is heated in a glass-covered box. The heat is transmitted through the glass is sufficient to raise the water to the boiling point, or very near it. Mr. Shuman has designed a low pressure steam engine in which this hot water is flashed into steam. Messrs. Will and Boyce employ their hot water to vaporize a liquid, which has a boiling point lower than that of the water, a liquid such as sulphur dioxide. The vapors which are given off from the sulphur dioxide at a pressure of 215 pounds to the square inch drive a specially designed engine and are then returned to be used over again. The water which has given up its heat to the sulphur dioxide is then through the hot box again to absorb more heat from the sun.

Since the sun does not shine by night even in the desert of Sahara, a storage system must be devised—a piece of apparatus that can be charged with excess power and tapped at will in sunless periods. Compressed air tanks, storage batteries charged by dynamo driven by the solar engine water pumped into a reservoir by a solar pump and used later to drive a steam wheel, have all been proposed. Messrs. Will and Boyce store their hot water in a well insulated tank, so that it retains its heat over night and is always hot enough to vaporize sulphur dioxide. Mr. Shuman has also designed an insulated tank or boiler for storing the water.

Prof. Fessenden, in the solar power scheme described and illustrated in the SCIENTIFIC AMERICAN two years ago, considered it more expedient to pump water into a reservoir and let it drop a considerable height against a water wheel. He, too, heats his water in a thin film under glass, causes the steam thus generated to drive a low pressure pump directly and then fills his reservoir with water. In the plant illustrated in the SCIENTIFIC AMERICAN he showed a way of lifting channel water to the top of the Dover Cliffs, so that it would flow back through a pipe and drive a water turbine at the bottom of the cliff. In conjunction with each solar plant a windmill is to be operated, so that, as he explains, "much better all-day and all-year efficiency will be obtained because wind is, as a rule, more effective during cloudy weather and at night time, i. e., when solar radiation is diminished or absent."

If we can extract heat from anything we can perform work. Water can be heated by the sun, and by reducing the pressure of the atmosphere. Since the atmosphere contains a certain amount of heat, why not extract it, as it were, and drive an engine? That is a proposal which Mr. Nikola Tesla has made. The number of miles the sun's rays travel before reaching the earth of Erismson, Shuman, and others seems to him commercially hopeless, however practicable it may be on an experimental scale. Moreover, he cannot reconcile himself to the idea that the entire manufacturing interest of all the nations is to be concentrated in Arizona, southern California, Egypt, or the Sahara desert, where the world's coal supply is exhausted and the solar engine is at last realized. Industry seems to be identified with the temperate zones, where sunshine is infrequent. The variability of sunshine, with which all solar engines must reckon, he finds an insuperable difficulty. Moreover, it seems inexplicable to him to convert the intense heat of the sun into low temperature heat, of which only a small fraction can ever be recovered.

Water can be heated by the sun, the only direct way of converting solar energy into work is to tap the heat units of the atmosphere, heat units available at all times, in fair weather as well as foul, in summer as well as in winter. There is no need to invent storage systems, for the atmosphere is its own storage tank. This is to be sure, but a thermometer reads as yet, but a dream which, however wild it may seem, is nevertheless worthy of at least moderate discussion.

### The Photo-chemical Power Transformer

Every living creature is a crude kind of solar engine. We are all dependent on the product of the soil for our existence, and that product in turn represents as much solar energy chemically stored up. A grazing cow is a living engine that converts solar energy into work. The solar energy that has caused grass to grow is turned to practical account whenever she ticks a fly from her back. Prof. V. Cohen has suggested that perhaps a chemical substance may be discovered, which, when exposed to the sun, is transformed into a stable substance capable of giving up its energy for subsequent consumption; a substance more efficiently than grass and capable of releasing its energy perhaps in an electrical way.

This idea was further developed in a profound analysis of photo-chemical problems before the recent International Chemical Congress by the distinguished Italian chemist, Prof. Ciamicin. An obvious cycle, he suggested, was the use of natural fertilizers to raise a harvest, which, dried by the sun, could be converted entirely into gaseous fuel, the ammonia being fixed and returned to the soil as fertilizer, together with the ash. He also deemed it possible to produce the things we need directly without the intervention of many factory machinery. If ammonia can be directly obtained from atmospheric nitrogen and hydrogen—the recent technical achievement of a great German chemical manufacturing company—why should it not be possible, he asked, to utilize solar energy in connection with catalytic substances and thus artificially reproduce plant processes on an unprecedented scale? A photochemical laboratory in northern Africa might thus produce immediately useful substances now supplied only after much consuming, engine-driving and mechanical handling of raw material. A meadow is not a highly efficient transformer of solar energy, but the manner in which it synthesizes the chemical elements stored in the earth with the aid of sunshine might well be artificially reproduced, and the solar engine itself then done except for purely thermodynamic purposes. If a plant can reverse the process of combustion, if it can transform the carbon dioxide of the atmosphere into starch, simultaneously setting free oxygen, why can't man adopt the same principle with success? At all events, Prof. Ciamicin holds that it lies within our power to make plants produce abundantly the things we need. The possibility is insisted upon, we consider the ease with which we have increased the amount of sugar in the sugar beet and the percentage of protein in wheat.

### The Energy of the Rotating Earth

In an introductory lecture to the engineering classes at University College, London, Prof. J. A. Fleming, in considering the sources of energy available for mankind, pointed out that the earth is a great flywheel! It whirls along in its orbit with a velocity of about twenty miles a second, at 280 times the speed of an express train. Its rotational energy is a hundred thousand million horse-power hours, but the total orbital energy or energy of motion in its orbit is ten thousand times greater. "Suppose," said Prof. Fleming, "suppose we could harness the earth's rotation so as to make the day just five minutes long. This would decrease the earth's angular velocity by about one third of one per cent and decrease the angular energy by about two thirds of one per cent, or say by 1/150. The sun's rays could capture and store up the difference in the rotational energy in the two cases. It would give us about six million million horse-power hours, or a billion horse-power for seventy thousand years. The energy we can obtain by the combustion of all the coal in the world is about 100 million tons of coal at present raised per year. This is only an insignificant amount when the enormous energy which would be set free by an almost imperceptible lengthening of the earth's diurnal rotation."

Prof. Fleming was not rash enough to indicate in what manner this untold store of energy might be utilized. Those who will attempt that will find themselves engaged in the mad task of designing perpetual motion machines.

### The Energy of the Atmosphere

If Ramsey is to be true, the heat of the atmosphere and land can be disregarded, have we not here a source of energy? Mr. William Ramsey has himself officially disposed of that possibility. First, all metals, except gold and platinum, he has pointed out, are produced by the combination of fuel, in the case of the elements derived from turbulent and dynamic. Hence they must be more costly than the aqueous unit in their production.

tion; to produce them, not merely much energy be used, but also some must be degraded, and lost as heat. Labor, too, is expended in their production. On the supposition of change with evolution of energy, they would give out no more than has been put in, in converting the raw into the metal. Lastly, supposing that this compound can be induced to change under the action of ultra-violet light, for example, the change is too slow to be effective as a source of energy, and ultra-violet light itself is produced only after much energy is expended.

Experiments conducted by Mr. Nikola Tesla with electromagnetic forces of 30,000,000 volts have convinced him that if 100,000,000 volts could be produced it might be possible to break down the atomic structure of any element and thus liberate a certain amount of energy. "But," he told the writer of this article, "even if the feat could be accomplished and sufficient energy set free, there still remains the enormously difficult problem of devising a means of utilizing the energy in a practical way."

Prof. J. A. Fleming suggests a somewhat similar course. "It is now pretty generally recognized," he argues, "that an atom is a complicated structure, a sort of solar system in miniature composed of revolving electric tracks. It may be possible to break down the structure by the action of ionization due to concentrated electric waves of the right period, setting up vibrations, which are resonant with some natural period of the atom, just as it is possible to break down a suspension bridge by a number of men jumping on it at times with its natural period of oscillation. If the atom were to break down, the energy liberated might be far greater than that applied to it in the form of the resonant impulses."

William Ramsay is undoubtedly right in maintaining that no source of energy, capable of being converted into work on a large scale, can be looked for, so far as the transmutation of matter is concerned. "The question is not—can it be done? but—does it pay to do it? And to the last question the answer is emphatically no."

#### Radium as a Source of Energy

So minute a quantity of pure radium as one gramme (one twenty-eight of an ounce) yields 118 calories an hour, 2,900 a day, or nearly one million a year. A ton of radium, according to Sir William Ramsay containing a million grammes, would give one million million calories per year. As the amount of radium in the earth is estimated at 100,000,000, one ton would evolve one million times as much, or 8,000,000,000, which is only the 17th part of that evolved by the radium in a year. Moreover, the radium after the year has suffered merely a minute loss of weight, while the amount of radium in the world is estimated at speaking about 1/3,000th of its weight has disappeared, hence before it was all "consumed" it would have evolved  $117 \times 3,600 = 420,000$  tons as much heat as an equal weight of coal. Add to this the fact that coal is utterly consumed in a few hours, but that rate of change of radium is all but imperceptible, and the superiority of radium over coal, weight for weight, is still more apparent.

Unfortunately, radium is about the scarcest producer of energy in the whole world. Radium is the offspring of uranium, it does not occur apart from uranium. Sir William Ramsay places the supply of uranium in his ore at about one million tons. Hence the amount of uranium contained in the "kulu" mine of Sweden is only 0.5 per cent. he calculates that the amount of radium metal in the whole world is not more than 500 pounds—too insignificant, in a word, for serious consideration as a substitute for coal. Not more than 120,000 tons of coal would be saved by utilizing the energy in 500 pounds of pure radium. The railway locomotives of the United States burn more than that quantity of fuel in a year. Besides, the energy in the five hundred pounds of radium cannot be liberated quickly, but must be spread over a period of centuries. The late Prof. Curie once remarked that he would not venture into a room containing only a pound of radium, so extraordinarily intense is its action. Hence, even if it were possible to hasten the discharge of radioactive energy, the engineers of a radium power plant must have to be recruited from the members of Marconi's Wireless Club.

#### The Internal Heat of the Earth.

It is a matter of common knowledge that in sinking shafts there is a rise in temperature of about 1 deg. Fahr. for every 60 feet, down to a certain depth. Active volcanoes are emitting fire from the core of the earth's internal heat. Have we not here an inexhaustible source of energy? We have, but it is difficult, if not impossible, to utilize it. If the prime requisite in making use of any source of heat is to obtain good conditions of air, the source with its air-laden electric waves would be found in the poor conducting qualities of rock. Only by solid convection could it be remotely possible to obtain communication with the earth's stores of heat. In considering these

possibilities, the Hon. R. J. Strutt points out that hot materials, while they have been utilized from time immemorial, are too dissipated. The powerful streams of molten lava that flow into the sea in certain localities, as at Stromboli, might perhaps be utilized here inventors. "But the opportunities for applying the method are not so widely and so securely open to encounter as they are."

Why not pump water down to the heated interior and return it to the surface at a high temperature? Here again Strutt sees no possibilities. The pipes sufficiently rapid transference of heat to them, on solid rock would be possible. For the same reason he states, the pipes must not be cooled down by the water flowing through them sufficiently to cause the surrounding lava to coagulate. Give the pipes enough, the prolonged action of molten lava! Wrought iron might be Strutt's opinion. On the other hand, the margin of difference between the melting point of lead and of iron is not very great, and lack of stiffness in iron pipes at such temperatures would undoubtedly introduce the most serious difficulties. Even if the attempt be made by directly attacking a volcanic crater the engineering difficulties would be enormous.

Similar conclusions were reached by Sir Charles A. Parsons in presidential address to the engineering section of the British Association for the Advancement of Science. He discussed the feasibility of constructing a bore hole twelve miles deep. While the heat would be accomplished, and while the temperature of the rock at that depth is probably not sufficient to undertake would involve an expenditure of millions.

#### The Future of the Windmill

A FEW years ago a collective report was made by the American census throughout the world on the use of windmills in their several districts and the prospects of increasing the sales of American windmills in foreign countries. At that time the manufacture of windmills in this country had increased fourfold in ten years, indicating a rapid growth in their use by our own people. However, the report was, on the whole, rather discouraging. The use of windmills was said to have recently decreased in the United States. This was notably true in Holland, the country with which the windmill is traditionally associated. For the great national task of draining the polders windmills were being rapidly replaced by steam pumps.

The machine of the future is the windmill. It is erected before the days of steam. This fact together with the relative inefficiency of the old-fashioned European windmills shows that the decline in the use of these devices allowed is no indication of the future in store for the American windmill.

The American farmer uses the windmill chiefly for pumping water both for domestic purposes and for irrigation. To some extent it has been used for driving the submersible pump of the farm. Attempts to use it as a means of generating electricity for lighting and power purposes have hardly passed the experimental stage. That this will come in time seems inevitable and herein probably lies the greatest future utility of the windmill as an adjunct in farming as well as in other occupations.

The future developments in this line will be conditioned by the meteorology of the country and in this connection it is important to have accurate statistics of the wind velocity in different parts of the country. Such information is presented in brief form by Mr. P. C. Day of the Weather Bureau in an article published in the last Yearbook of the Department of Agriculture. A number of charts bring out clearly the wind velocity in windmills in different parts of the country. Mr. Day takes a most hopeful view of the value of the wind as an asset in American agriculture.

#### The Current Supplement

IN this week's issue of the SCIENTIFIC AMERICAN SUPPLEMENT Mr. W. M. Booth discusses industrial efficiency from the point of view of the chemical engineer. Mr. P. W. Wilcox describes a new system of two-rod electric motor for the purpose of the electric motor. "The Hoofbeats and How It Spreads Disease," in which he points out as a possible remedy against the fly pest a fungus which is parasitic upon the fly and kills it. W. M. Davis writes on the theory of the origin of coral reefs by submergence. The "Waters of the World" and amusing incidents from his connection with the early development of the telephone. Walter Fold describes the direct production of ammonia sulphate from hydrogen sulphide and ammonia. J. J. Thomson's work on the "Structure of the Atom" begins in this week's issue. "Cooling Towers are of importance in many manufacturing plants. A special system of such towers is described, and their efficiency discussed." Mr. N. R. Nash concludes his article on Ferrosil and Ferro-

### Clipping a Hedge with a Torch

To the Editor of the SCIENTIFIC AMERICAN.

The day fast approaches when the hedge that isolates our suburban home is about to start in business and one must therefore consider the matter. I am, I think, the question. Have any of your readers ever tried to 'chip' a hedge with a painter's gasoline torch?

NEW YORK CITY.

### The Mississippi Floods

To the Editor of the SCIENTIFIC AMERICAN.

I am sorry to note the stand you take in the matter of straightening out a river, in your otherwise sane view of flood restrictions.

The problem of the Mississippi is identical with that of the brook, save in magnitude and constant level at outlet. A straightened bed will lower the flood crest by drawing the advance waters of a flood from hours to days before they reach the outlet. Thus, a large volume of oncoming waters is early disposed of, and the flood crest flattened and drawn or heightened. This is surely a well-known fact, and easily demonstrated fortunately.

The importance of bank erosion is a case second to that of flood restriction and is happily prevented by simply straightening the channel. Such this plain problem does not call for very much "gray matter." Begins at the mouth of the stream, and any distance make waterway wide enough and that high enough to take flood, with a good margin of safety added. Littleton, Del. C. A. ZANDER

### Improvement in Carburetors

To the Editor of the SCIENTIFIC AMERICAN.

Much is being said about the carburetor air valve working in connection with the carburetor. I have used such air valve three years, the valve being under hand control. By its use the increase in mileage runs from sixteen to twenty-two and twenty-five miles per gallon. The machine is small and simple.

A simple device for air hand control can be put on any car without much trouble. Cut a hole in a suitable place between the carburetor and engine, and insert a valve, and connect it with the carburetor by a lever on the steering post. For a small car a three-eighths-inch hole covered with a cone valve will serve. Experience on the road will tell when to open the air supply if opened too soon the engine will miss, if opened too late the engine will stall. The harder the engine is working and the faster it is going, the more the valve can be opened.

The use of the auxiliary air valve is not original with me. I got the idea from Homan's work on "Self-propelled Vehicles" using my own plans to accomplish the job. The material cost thirty cents. The work was done in a carpenter's shop, rather crude, of course, but answers an excellent purpose.

Pasadena, Cal.

WILLIAM YOUNG

### That Granite Chipping Machine

To the Editor of the SCIENTIFIC AMERICAN.

I notice the article in your correspondence column of February 22nd, in which a machine is wanted for chipping granite cubes, which is certainly much to be desired.

This city alone uses from eight to ten million a year, and nothing else seems to be able to stand up under heavy conditions of traffic. Advance has been made in every line of industry except the granite block industry, which has stood still for upward of two hundred years, save that drilling is now done by pneumatic tools instead of hand drills, but nothing has as yet been devised that will even compete in cost of production with the present extravagant methods of hand labor. There are firms in this city in Chicago who would no doubt advance money for any plan that appeared practical and pay handsomely in royalty for machine or any contrivance that would equal the present hand labor cost of getting out these granite blocks.

Through all this middle west there are two sizes in general use. One is 8 inches to 12 inches long, 4 inches to 5 inches in width, and 5 inches to 5½ inches in depth, the other is 6 inches to 10 inches long, 3½ inches to 4½ inches in width, and 3½ inches to 4½ inches in depth.

To the man or the men who can devise something practical along this line, a fortune awaits them.

REPAIRER CONSTRUCTION COMPANY,

Chicago, Ill.

For J. A. McGINNIS.

## Harnessing the

Progress in the

W. C. J. Bird

The Boise project, Idaho. Bird's eye view of the completed power plant and surroundings.

UPON the adoption by Congress of a comprehensive and practical water power policy depends to a great extent the future development and progress of a large part of the West and in a somewhat lesser degree of many parts of the East, South and Middle West. The time is ripe just now for an adjustment of the differences which have existed between the local authorities, the States and private interests, and a definite policy is looked for in the near future. Indeed a long step in this direction was taken during the closing hours of the last administration when plans for State and Federal co-operation were formulated and the Department of the Interior in an agreement with a large power company in Montana secured recognition of its right to make certain provisions for the regulation of rates to govern the operations of this company which desired to use some of the public domain. As a result of this agreement the electrification of probably four hundred miles of a transcontinental railway is practically assured and a new market for the white coal of the West is provided. A precedent

which resulted in a comprehensive revision of the regulations governing the water power permits in national forests and on the public domain generally. Later a largely attended conference was held with representative water power interests and of the State conservation water and varied commissions of California. There were discussions of the relations between the State and national governments with respect to water power and modifications in the laws and regulations in order to co-ordinate the functions of the nation and the States. This conference was extremely illuminating in that it fully demonstrated the feasibility of effective co-operation.

### Government Construction of Power Plants.

In the working out of a definite plan for the utilization of our natural resources and particularly the water powers, only one Federal bureau has been actually engaged in the engineering work of developing power. The Reclamation Service, organized in 1902 for the purpose of making habitable large areas of irrigable public lands, has constructed a number of

power plants and has launched the Government in the power producing business in several localities. Originally the idea of power development was solely for the purpose of pumping water to lands above the reach of the gravity canals, but wise management developed when there was demand for surplus power, that all such power which could be economically developed should be provided for in the construction of the plant. In this way the Government has found itself in the field as a maker and seller of electric power. It is a rather advanced step in governmental activities, but no one has yet seriously questioned its practicability and certainly no one can gainsay its success financially. It is understood that the Government's control of these public utilities is not to be permanent, as it is contemplated in time that their operation and maintenance as well as the revenues will be turned over to the people who have assumed themselves to repay to the Government its investment. The Government in this connection might be regarded as in the position of a contractor who has built and is operating its plant until its owners have met their obligations to him.

The following table shows the present condition as well as the possibilities of power development on the reclamation projects.

Project.	Power Developed, H. P.	Possible Power, H. P.
Ariz., Salt River	9,000	20,000

\* Not determined.

**Minidoka Project, Power Plant.**  
The largest individual development of

has been established and the burden of Government regulation lying up development has been laid on the shelf for the time being. If one of the largest power companies in the West and a transcontinental railroad have found it possible to enter into an entirely satisfactory agreement with the Department of the Interior notwithstanding the present notoriously inadequate laws, future complaints by promoters and exploiters that their plans for development are prevented by departmental red tape will perhaps not be accepted with the same confidence by a public and the press. It has not always been the fault of the Department that private enterprises have been checked and limited. More often the fault has been with Congress, which while enacting laws for withdrawals and reservations has persistently declined to provide legislation to enable the Department to unlock the storehouse in order to permit utilization and development for the public.

Representatives of the Departments of the Interior and Agriculture during the past year held numerous conferences

The great Minidoka dam across Snake River.

power by the Government is on the Minidoka project in Idaho, where at the present time 10,000 horse-power is utilized. It might be stated that on this project as well as on all others the primary use of this power is to meet the needs of irrigation. After this need is supplied the surplus, if any, is marketed commercially for the needs of the public and private interests.

The Minidoka power house is located in the great Minidoka dam across Snake River. The water which moves the turbines is water which does not belong to the Government, but is decreed by prior right to irrigation projects below, in the neighborhood of Twin Falls. Before it is permitted to pass to its rightful owners the Government exacts a toll of 10,000 horse-power, which is advantageously applied to many uses on the Minidoka project. The first and greatest use is for pumping up on high lands. The current is generated in five separate units of a total of 7,000 kilowatts and transmitted about 15 miles at a pressure of 70,000 volts, to three pumping stations which pump about 650 cubic feet per second to a height of 31 feet above the gravity canal. At this level 10,000 acres are irrigated, the balance of the water being then lifted 31 feet higher, and part of it applied to 15,000 acres. The remainder is then lifted an additional 31 feet and supplies 23,000 acres. This constitutes the largest pumping plant for irrigation in the world. Notwithstanding the large utilization of the power for irrigation needs there remains a substantial surplus for which it was necessary to establish a market. Being a constant force, and not limited as on several other projects to the irrigation season it was important that arrangements should be made to dispose of the unused power. The heaviest demand for electrical energy occurs during the irrigation season. In the winter this demand ceases entirely. As the flow of the stream continues throughout the year, power is available in winter as well as in summer, and it has been deemed expedient to make special inducements to the towns on the project to use it. Encouraged by a very low price, citizens of Burley, Heyburn and Rupert have made contracts with the Reclamation Service. At the prices made to them they can be furnished by means of electric heaters at approximately the price of coal. Its greater convenience and cleanliness has led to such use to a considerable extent. The demand is steadily growing, but still is behind the supply. In addition to heating and lighting the stores and homes, the family cooking in many homes is now being done by electricity.

A very advantageous contract was made a short time ago with a newly established sugar factory at Burley. The first month's rental of power produced a revenue of \$1,800 to the Government.

An effort is being made to secure the consumption of the balance of this water power by encouraging the installation of a manufactory of nitrogen products for fertilizer and other uses. It is believed that these negotiations will prove successful as well as others for establishing special industries adapted to intermittent use of power.

#### The Salt River Project, Arizona.

On this project, by reason of its large storage, the all-year-around irrigation, and numerous drops in the main canal, the power possibilities far exceed the requirements of irrigation pumping. Owing to the varying head in the reservoir, which is to be utilized upon the wheels, the power is fluctuating in character at the Roosevelt dam. This disadvantage is compensated for in a measure, however, by the fact that the demand for power is great and the rate obtainable sufficiently remunerative to warrant an expenditure on the part of the Government necessary to develop a plant of maximum capacity. The surplus power at the Roosevelt dam has been leased to a prominent mining company which, owing to the high cost of fuel, found it profitable to pay  $\frac{1}{2}$  of a cent per kilowatt hour for all power taken under a contract which does not obligate the Government to continuous delivery. This of course forces upon the company the necessity of having in readiness at all times an auxiliary steam plant for operation on short notice. Under this same contract the Government may in time of need use the steam plant of the company for its own purposes. This most fortunate conservation of the entire power possible at this point will in the long run prove profitable to the irrigators under the project.

The co-operation of the farmers and their appreciation of the value and importance of developing all the power possibilities in the valley are evidenced by a bond issue made by them recently in the sum of \$500,000, which amount is now being expended in accordance with plans of the Reclamation Service to construct a number of power plants in the valley, utilizing the drops in the main canals. One of the canal power plants is serving to supply a local community which delivers power to the city of Phoenix. The revenue to the Government for this power amounts to between \$5,000 and \$6,000 per month. Another con-

tract has been let to the Sugar Company at 14¢ cents per kilowatt hour, another to the town of Glendale at a maximum of 5.5¢ cents per kilowatt hour, another to the Arizona Alfalfa Mill Company at 14¢ cents per kilowatt hour, etc. It is conservative to state that the ultimate gross revenue from the power on the Salt River project will exceed a million dollars annually when the maximum development has taken place.

It should not be forgotten that notwithstanding this large revenue return in the way of cash rental for power the same plants will pump water from wells to irrigate 40,000 acres. As this land comprises some of the finest orange land in the valley it is safe to say that electric power will in this way add \$250,000 to the taxable wealth of the valley in land values alone. In producing orchards the land will be worth double this amount.

#### Strawberry Valley, Utah, Project

On this project the Government planned its power plant primarily for the purpose of using the electrical energy in the construction of a remarkable tunnel. A description of this tunnel was published in last week's issue of the *Scientific American*. It pierces the Wasatch range at a point where the mountain is four miles thick and conveys the water of a stream formerly emptying into the Gulf of California into a valley which has no outlet to the sea. From the power plant on the western slope to the eastern portal the distance was 25 miles across a rugged mountain country. The waters of Spanish Fork River were diverted into a power canal which supplied the turbines and about 1,000 horse-power was developed. Part of this power for some time has been leased to the town of Spanish Fork, Payson and Salem at rates ranging from  $\frac{1}{10}$  cent to  $1\frac{1}{2}$  cents per kilowatt hour, the lower rate cutting for a minimum total of \$225 per month and the higher rate for \$400 per month.

#### Electric Power for Construction

The Reclamation Service has not hesitated to install heavy power plants in connection with its construction work in the West. At the present time it is building near Hobe Island the highest dam in the world and is using for this purpose power transmitted 24 miles from its power plant on Hobe River where 1,000 horse-power are developed.

On the Truckee-Carson project in Nevada 1,000 horse-power are granted in the Government plan a portion of which is required in building the Libmon (Continued on page 323.)

## Suspension Insulators Suitable for 110,000-volt Transmission

Tests Showing the Weaknesses of Standard Types

By Joseph B. Baker

THE constant tendency to increase the voltage of electric transmission lines in order to deliver energy over longer distances and with reduced line loss has presented for solution many problems of insulation. Both the terminal apparatus and the connecting lines must be insulated so strongly that the high pressures employed and especially the abnormally high potentials due to sudden and transient surges, will not result in breakdown of line or apparatus with its serious consequences. The resistance and dielectric strength of insulations used in electrical machinery at generating and sub-stations—generators, transformers, rotary converters, etc.—has been well worked out by design engineers and electrical manufacturers in response to the demand for higher and higher voltage equipment, but the protection of the line itself, which is not localized in a small space under a sheltering roof but runs for many miles through the open country, strung overhead on poles and exposed to all atmospheric conditions, has been in a comparatively backward state. In the old days, when generators and transformers were built with shelled cotton insulated wire windings, the lines from the power station were strung on ordinary glass insulators, like those used for telegraph and telephone wires. Later, when better insulations for the machinery were developed in recognition of the fact that high and durable insulation is an essential of continued and economical operation the pole lines likewise received attention, and special porcelain insulators began to be used, but up to a very recent date high-tension line insulators—nowadays consisting of a series of insulator sections, or units, affording a long and high resistance barrier against leakage of electricity—have been designed more in accordance with the individual views of their makers than with any

definite electrical and mechanical requirements.

In a paper recently presented before the American Institute of Electrical Engineers, Mr. J. W. Kohnman of New York describes an investigation of a number of different types of high-tension suspension insulators that he made in order to select a suitable high-tension insulator for a transmission line operating at 110,000 volts—a voltage at which the question of insulation is of the greatest importance since very little reliable data was available as to the operation of insulators for potentials above 80,000 volts.

At the outset of this investigation, upon visiting the different insulator factories and witnessing manufacturers' tests on insulators which they proposed for this work it was clearly seen that the most widely varying methods of testing were employed so that an insulator showed entirely different results, depending on where and by whom it was tested. There seemed to be no recommended standard in the testing conditions or in the method of interpreting the effects observed; so that it was impossible to arrive at definite conclusions of value in the actual installation of the insulators on a power transmission line. For the new investigation it was therefore determined to establish absolutely unvarying conditions and a definite line of reasoning to be followed in classifying the results obtained.

The testing equipment was one having plenty of power (as well as high voltage), and was so arranged that the conditions could be controlled and changed at will. For the open air electrical tests of the suspension insulators, a piece of gas pipe was supported horizontally, resting at each end on a 60,000-volt pin-type insulator at a convenient height above a large platform. The general view of the testing apparatus for suspension insulators shows several of these insulators

hung vertically from this gas pipe support, but the insulators were tested only at a time, being placed in the middle of the support while under test, with all the other "candidates" crowded to one side out of the way. The same platform and arrangements were used for the electrical tests of the strain insulators that were investigated, except that the insulator under test was held by tackles in a horizontal position with two other insulators at the ends of the tackles to prevent leakage to ground. For supplying the testing voltage two 50-kilovolt, 150,000-volt transformers were used, giving a maximum voltage of a little over 300,000 (300 kv). The voltage was controlled by a water rheostat in the low-tension circuit, and readings were taken on a special voltmeter calibrated with spark-gap.

The tests on each insulator comprised "dry tests" consisting of a flash-over test on each section of the insulator in order to exclude defective or punctured units, and a potential test on the complete insulator and on a few number of sections than the total number in the insulator, wet test (insulator exposed to artificial rain), test of all of the insulators in parallel, in order to observe closely relative performance when exposed to identical voltage and conditions, puncture test, with the insulator immersed in oil, since the potential required to puncture a sound insulator is greater than the flash-over voltage, test of mechanical strength made with a simple pulling contrivance and dynamometer. An interesting feature of the work was the method of simulating rain, in the wet tests—by an adjustable comb of water-pipe nozzles arranged to shower the "rain" over the insulator. By using two groups of nozzles and adjusting their distance from the insulator under test, the angular precipitation of their streams and the amount of rain supplied per

Type D with hook unprotected.

Testing platform for suspension insulators.

Type D protected by bottle-shaped shield.

minute (measured by a special rain-gage) was placed under perfect control.

The electrical tests illustrated were made at night and in complete darkness, so that distinct observations could be made of all electrical effects by the eye and by the camera, and the photographs which constituted a permanent record of the work were identified by the time shown by a clock placed near the insulator under test. The voltage applied to the insulators was raised by successive steps. Assuming that the luminous display was in proportion to the power leaking past the insulator, it was deemed fair to judge the quality of the insulator by comparing the amount of the display and the voltage that was required to give same. In deciding the net relative value of a given insulator and the influence of its design, other observations were considered: the gradual increase of luminosity, or the appearance of a sudden display, on raising the voltage, the appearance of the display at certain points and not at others on the insulator, etc. The five types of suspension insulators as seen by daylight, and one of the strain insulators that were tested, are shown herewith. The photographs on the opposite page illustrate the performance of the insulators under strain at an angle of 45 degrees and at the rate of one half inch of water per minute.

Type A met the mechanical requirements (by showing a breaking strain exceeding 5,000 pounds) but not the electrical requirements. As the voltage was raised a discharge became visible at 100 kilovolts, and the

luminous discharge, presents an interesting study. This insulator failed to meet the mechanical tests only because the cement joining the different pieces in each unit had not properly set. It met the electrical requirements well, showed high-class workmanship and material.

Final selection of the Type B insulator was made in consideration of its good electrical points as demonstrated by the tests on the eight-section insulator, and because better deliveries could be made for the actual line construction than could be expected for the four-piece insulator, Type F. The large number of open spaces in this unit are of advantage. Although the insulator did not meet the mechanical specification requirements (owing to the fact that the cement had not properly set, the insulator broke at an average stress of 7,000 pounds, the required breaking stress being 8,000 pounds). It was judged to be strong, light durable, and compact and susceptible of improvements by slight changes in the design. A subsequent increase in diameter increased the electrical efficiency substantially, and the method of connecting units together was modified so as to prevent a smooth and symmetrical surface to prevent premature discharge.

The strain insulator Type C did not meet the requirements under the wet test by reason of the excessive leakage at potentials below the specified standard of 220 kilovolts (below the line voltage). Other types that were submitted for test having also failed a five-unit Type B insulator with a modified design of cap

rated from one another. (Capt. Ritcher said that the expedition had only provisions for one month at the time and that most of the party were holed in the last stages of snow.) Nothing is known concerning the fate of Schröder-Strana and his companions, nor of two Germans, Dr. Behners and Dr. Moser, who took a different route from the rest of the party after leaving the ship. The situation of the whole expedition appears to be precarious.

## The Destruction of the German Dirigible "L. Z. 15."

By Carl Dienstbach

SO many trips have been made in safety by the giant Zeppelin airships within recent months that the disappearance indicated by the frequent reports of the past, was all but removed. Indeed, German airship builders were taxed to their utmost in the effort to construct new rigid vessels. In the midst of this development came the news of the destruction of the most modern and improved though not the largest, of the Zeppelins, the new military L. Z. 15.

How did this accident happen? So far as can be at present determined this seems to have been what may be called a "bottle-neck" accident, in other words an accident no more avoidable than are the accidents to which trains and steamships are subject. It happened during a storm which played havoc with some shipping in the harbor of Hamburg and caused many deaths

Type A.

Type B.

Type C.

Type D.

Type E.

Type F.

### Suspension insulators submitted for test

Types A, C, D, E, and F are regular suspension insulators. Type B is a proposed strain insulator

insulator broke down at 100 kilovolts. The appearance of this five-unit insulator at 100 kilovolts shows the insulator breakdowns as due to excessive leakage, the entire insulator virtually becoming conducting. There was another important feature characteristic of every insulator having metal fittings which are in the least degree non-symmetrical about the axis of the insulator, viz., the uneven static field or dielectric stress, most intense at projecting metal points and always causing premature failure of the insulator, the discharge of the insulator is started in almost every case at the projecting point.

Type C insulator also showed up better mechanically than electrically, although it was judged to be too fragile in ordinary handling. It began to show luminous effects at 250 kilovolts, and failed by flashback at 300 kilovolts. This insulator furnished another instance of uneven dielectric stress, the effect of which is very marked in the reproduced photograph of the insulator in the act of breaking down—particularly at the point of discharge at the left of the cap in the second section from the top.

Type D is shown breaking down at 190 kilovolts by flashback. The illustrations of this insulator under test show the localized discharges from projecting points and backs of the hooks used to link the sections together, and the marked effect of protecting the hook by a bottle-shaped metal shield giving a symmetrical instead of a non-symmetrical metal surface.

The eight-unit Type E insulator is shown in the act of failing at 410 kilovolts in consequence of strong leakage from section to section. Heavy discharges are coming at the outer pins by the caps.

Type F, an insulator of Norwegian design and manufacture, made the best showing of all. The photograph shows this five-section insulator flashing over from section to section at 300 kilovolts. The performance of each section, revealed by the aspect by the

to increase the strength, was finally adopted as the least unsatisfactory strain insulator to use

### Serious Plight of an Arctic Expedition

A PARTY of Norwegianians under Capt. Skarred has known from Tromsø to the rescue of the *Schneider*, a German airship, now supposed to be in dire straits in Spitzbergen.

It will be recalled that Lieut. Schröder-Strana, a German, recently organized an expedition for the purpose of making the Northeast Passage, an undertaking which, along with much incidental exploring, *en route* was expected to take three or four years. The party included eleven Germans—some of considerable sea and land experience—and five Norwegians. In order to obtain preliminary training under Arctic conditions, a trip to Spitzbergen was undertaken last summer. The party sailed early last August in the ship *Hermes* from a two-master of 61 tons, under the command of Capt. Ritcher, and at first attempted to push north along the west coast, and the leader, with three companions, left the ship for a trip over the pack ice in the hope of reaching and crossing Northeast Land while the vessel put into Tromsø Bay to await their return.

On September 10th, as Schröder-Strana had not returned and the ship was frozen in for the winter with but a meager supply of provisions on board all the German and two Norwegian men set out on an attempted overland journey to the American coast near Adolph Bay and the neighboring wireless telegraph station at Green Harbor. Only Capt. Ritcher succeeded in reaching Advent Bay, on December 27th, after suffering great hardships. The rest of the party had split up into several detachments and had mostly taken refuge in three Norwegian fishing huts, widely sepa-

rated from one another. The safeguards with which all Zeppelins are now provided as a result of former disastrous experiences, proved inadequate in this particular case. It is now the rule that in a storm a Zeppelin may land only on perfectly level unobstructed ground and at a distance, moreover, sufficiently far from any building or other large obstacle which may churn up the wind. According to the orders the airship is not anchored, but only held firmly moored with cables running. If a heavy gale threatens destruction the ship is immediately released so that it may seek refuge in the air. When the danger has subsided the vessel may return, taking the first favorable opportunity to glide into its shed. The writer saw the *Hermes* enter the shed at Hamburg with the men holding her and running as fast as their legs could carry them, two of the airship's propellers were bent in the process.

The L. Z. 15 had been navigating in heavy weather for sixteen hours, and had landed only to replenish her fuel, nearly all of which had been utilized in overcoming the storm. The attempt to anchor the ship so as to facilitate the replenishing of the fuel supply, was the primary cause of the accident. To have ascended again without sufficient fuel would indeed have been hardly less precarious.

The L. Z. 15 had just been accepted by the military authorities. Consistent with her military use was there a strong reason to believe that had she been handled by the old, seasoned air dog's of the passenger service many of whom were veteran seamen she might have escaped injury. As it was, she was wrecked by tremendous gales which pounded her against the ground before she had been completely anchored. All the machinery and equipment remained intact. No one was injured. It may be safely predicted that in the future a sufficient amount of fuel will be kept on reserve in the capsule of all Zeppelins, whether their ships are engaged in the military or the passenger service.

# Fighting the Chestnut Bark Disease

The State of Pennsylvania's Work

THE State of Pennsylvania is waging a strenuous warfare against the spread of a destructive pest known as the chestnut bark disease. This thoracic attempt on the part of the State to control so virulent a disease is unique in that it is the first organized endeavor of its kind where the disease was first recognized as a real and serious menace to the chestnut trees in the vicinity of New York city in 1904. Not relying upon mere individual effort, Pennsylvania opened in 1910 an official contest with this pest and at once began to in- vestigate the disease itself and to con- trol its spread. In this time the disease had been reported from nine States, but with insignificant like efforts and their en- gagement no less than an entire step in the advance of the disease is sought. This undertaking of the State is being closely watched by pathologists and foresters all over the world, and it is regarded as one of the greatest problems in vegetable pathology involving the application of means of pest control and extermination which have never before been put into practice on such an extensive scale. Yet vegetable pathologists claim that the control and ultimate extermination of the *Diplodia* parasite, as botanists call the chestnut bark disease, will sooner or later become a real accomplishment.

Viewed even in the most hopeful way this invasion of a comparatively new pest is a fearful portent to the chestnut throughout its entire range of growth and threatens a total destruction of one of our most valuable timber trees. If the blight goes unchecked distributed over all the States in which chestnut trees were naturally the problem will become infinitely more difficult. The magnitude of the task of controlling the spread of the disease which still remains fairly well con- cealed in certain areas, cannot be over- estimated. It is realized that this menace in its condition of advance is too formid- able to be engaged with even by the thor- ough organized State experts. The dis- ease is decidedly of national importance and for this reason the United States De- partment of Agriculture is co-operating in the work and is doing everything in its power to aid the State in the great under- taking. Literature warning against the pest is officially circulated throughout the chestnut belt and especially within the districts adjacent to the infected regions. The aid of the private owners of timber lands is solicited and thus far a good many have volunteered to co-operate with the State authorities to remove all sus- ceptible infections.

The spread of the chestnut blight is westward across the State and the object of the Blight Commission is to check its advance. This is done by felling all in- fected trees along the border of the blighted zone. The bark is carefully re- moved from the merchantable part of the trunk and burned together with the branches and small twigs. The bark is also removed from all stumps and burned. To quote from one of the official reports of the Pennsylvania Chestnut Tree Blight Commission:

The advance line at the present time ex- tends through eastern Bedford county to cen- tral Uniontown Center and Uniontown, Trappe and northwestern Bedford counties. Up to the present time over 25,000 blighted trees have been destroyed in the western part of the State. It is estimated that by the end of the year 1919 the disease will be well established in the western part of the State. It is hoped that by the time this way it is hoped to have the disease from advancing further across the State.

A great amount of useful systematic work against this dreaded bark disease has been done since the State undertook its control and eradication. As perfected here the methods become that the spor- adic outbreaks along the line of advance of the disease are quickly located and the

The spread of the blight is westward. To check that spread it is necessary to cut blight-killed chestnut into cordwood, oak and other hardwood remain.

Sample of tree surgery. A healed wound of canker was removed. The treatment of cankers is resorted to only in cases of ornamental trees.

Spraying with Bordeaux mixture is thoroughly impracticable and is carried out only in cases where a few trees are to be saved.

Spraying outfit used at Kennett Square, Pennsylvania. Spraying can be done only on a small scale and serves merely to disinfest wounds or abrasions in the bark.

Cutting blight-killed chestnut into lumber. The trees are felled along the border of the blighted zone. The bark is carefully removed and burned; the merchantable part is sold.

trees destroyed. Burning is the only practical destroyer of this fungus, and every spot in the forest that is infected is located and the search for them is continued. The expert does his work well, but after him comes a still more competent searcher or after him possibly still another picked from the long list of available field men. The work has progressed sufficiently far to say that local control of its spread has been effected by this method of double, triple, and in some cases quadruple checking or locating spots of infection of trees. It is hoped that by thoroughly thorough working from the circumference to the center the authorities will be able to keep the pest securely penned. As in all animal and vegetable pathology, prevention is the best cure. Other methods of controlling its spread are employed, and the one which has hitherto met extensive operation in the press is the well known, though thoroughly impracticable, method of spraying with Bordeaux mixture. The purpose of spraying, which can be done only on a small scale is to disinfest all wounds or abrasions in the bark, which would otherwise serve as a means of entrance of the spores of the fungus. If the Bordeaux mixture comes in contact with the spores it will prevent their germination. As soon as the spores have gained an entrance in a fresh untreated wound they will germinate and spread very rapidly in all directions in the living inner bark until the mycelia completely girdle the tree attached. A canker is developed wherever the fungus succeeds in gaining entrance, and if these spots are discovered before the fungus has crept the trunk or branch they may be removed by cutting out the lesions and waterproofing and sterilizing the wounds. The water proofing material used is a mixture consisting of two parts of lime and one part of creosote with sufficient lamp oil to make it spread easily. Rods are also used to supplement the tree-surgery in the trees that have been sprayed with Bordeaux mixture.

Burning as has been said above is impracticable and is employed only in cases where a few trees are to be saved. It has been demonstrated that spraying acts as a preventive to the germination of the spores of the fungus which causes this trouble. On a large private estate at Kennett Square Pennsylvania about fifty large chestnut trees were saved by the spraying process. The trees were sprayed every five days or two weeks from April to November in 1912. These are now in a healthy condition, and as far as can be determined by close examination show scarcely any signs of blight. A few trees in the woodlot which were not sprayed nor surgically treated had to be removed because they were all badly blighted.

The treatment of cankers is resorted to only in cases of ornamental chestnut trees and of horticultural varieties planted in orchards. The results so far attained with this method of local treatment have more than justified the necessary outlay. Backed thus far by a liberal appropriation the Commission has succeeded in preventing the pest from acquiring very serious headway.

## Night Plowing

A NOVEL departure is reported to have been made in New South Wales by starting plowing at night. For this purpose two powerful acetylene headlights are attached to the traction engine which draws the plow, and the ground is so well and brilliantly lit that the operator can work over the field quite as well as by daylight. The use of these headlights frequently leads to many improvements in the application, operation and adjustment of the lights.

# The Recent Storms and Floods

A Remarkable Series of Cataclysms

(Photographs copyrighted by Newspaper Enterprise Association)

One house blown against another A curious result of the tornado's power

THE storms and floods of the latter part of March, 1917, will rank among the greatest meteorological disasters in the history of this country. It is too soon to attempt a detailed analysis of these occurrences, from either a theoretical or a practical point of view, since up to the present writing both Weather Bureau reports and press dispatches from the stricken district are much curtailed by the interruption of telegraphic and other means of communication. The salient facts, however, may be stated as follows:

On Sunday morning, March 25, a well defined and symmetrical cyclonic disturbance over the western half of the United States with its center over Colorado. The winds were everywhere moderate and, except all the cyclone did not exhibit any of the characteristics regarded by weather forecasters as harbingers of tornadoes. The morning weather map of that date shows none of the distortion of the isobars into a V-shape that indicates a tendency to line-squalls. At 8 P. M. (Eastern time) the storm had moved into a direction and at a rate that was in no way abnormal and was central near Omaha. The isobars were still symmetrical. For some reason that is hard to explain from the weather maps, violent thunderstorms and scattered tornadoes occurred Sunday afternoon and evening over a broad zone on the right side of the cyclone's path. It is especially remarkable that a tornado occurred at Omaha almost at the very center of the cyclone, at about 6 P. M. local time. As a rule, tornadoes develop several hundred miles southeast of a cyclone's center.

From the fragmentary information now at hand, it appears that the tornadoes which occurred in Nebraska, Iowa, Illinois, Indiana, Michigan, and Wisconsin occasioned an aggregate loss of about \$400,000, that some 700 people were injured and that \$5,000,000 worth of property was destroyed. Much the heaviest losses occurred at Omaha but this does not mean necessarily that the winds were more violent at that point than anywhere else; the area of devastation in a tornado is always small, and the amount of damage done in a populous city is, of course, much greater than in small towns or the open country.

In their destructiveness the tornadoes of March 26-27 were among the worst this country has ever experienced. In the number of fatalities by which they were attended they have probably been surpassed only by the tornadoes of May 24-26 to 27th, 1896, which included the terrible St. Louis tornado of May 27th. The latter, though not relatively severe, passed through a great city and destroyed 306 lives, besides damaging property to the value of twenty thousand dollars. The cyclone that occasioned the recent disasters passed into western Canada on

Automobiles were blown down from a viaduct.

A resident of Omaha collecting his belongings after the tornado.

Monday and rapidly left the continent. In the meantime a long trough of low barometric pressure spread up from the southwest and by the morning of March 25th its axis extended along the whole length of the Ohio Valley. It was attended by heavy rains especially over the northern watershed of the Ohio where equally heavy rains had occurred on Sunday and Monday in connection with the previous depression. This continuous downpour turned the northern tributaries of the Ohio into raging torrents and on the 25th the southern valleys of Ohio and Indiana were submerged. The conditions were unprecedented. Previous great floods of the Ohio Valley have generally been due to the main river overflowing its banks under these circumstances, the antecedent conditions usually give ample warning of what is to happen and the progress of the flood crest down the stream is relatively slow. In the present case a huge freshet occurred suddenly in the whole complex of smaller streams on the northern watershed, where the elaborate system of river-gages and rainfall stations which mark flood prediction in the main river on an ensue task, was of no avail.

On the 26th the rainfall area spread over the southern watershed of the Ohio and the enormous contributions of water from both sides soon raised that river above flood stage. The colossal disasters, however, which will make the floods of March, 1917 historic, were those which came unbidden on the 26th along the northern tributaries of the Ohio. The details are still fresh in the public mind and need not be recapitulated here. By the 27th the critical area had passed west to the Atlantic seaboard and was followed by a rapid fall in temperature over the flooded region, greatly adding to the suffering of the homeless people. The storms and floods had paralyzed the rail ways and the telephone and telegraph lines so that the work of rescue in which the whole nation co-operated was greatly hampered.

A practical consideration in connection with this appalling flood is that though it is altogether unprecedented in magnitude in the history of the region concerned it may be equaled or even surpassed in the future, unless some rational measures are taken to control the head waters of our great rivers.

**An Improvement in Electro Deposition**  
A patent has been granted to Nicolo Coudanelli of Genoa, Italy, for a process and apparatus relating to the electro deposition of metals and wherein a multiplicity of loose small relatively heavy bodies are arranged in the receptacle for electrolyte and which will operate to heat and roll upon the coating deposited in order to render it more compact and resistant.

### A Cascade of Stone

A REMARKABLE miniature formation due to be found in Algeria about six miles from Constantine, the ancient city. It looks like a magnificent cascade with the water in violent motion pouring over a rocky cliff in turbulent and riotous confusion and yet the cascade is as motionless and silent as the photograph reproduced herewith. It is as though a great waterfall had suddenly turned to stone. Naturally the natives look upon this phenomenon with great awe. They have given it the name *Hamman Meekhatin* which means the bath of the damned. They have a legend that the waterfall was turned to stone together with the number of an infidel who had incurred the wrath of Allah. At night these petrified individuals according to the story are restored to life and assume their normal shapes. The petrified waterfall has been produced by calcareous deposits from hot sulphurous and ferrous mineral springs. The springs have a temperature of 73 deg. Cent. The deposits have, of course, been making for many centuries. The hot springs were known to the ancient Romans. We are indebted to the *Illustrated London News* for these facts and for the accompanying photograph.

The petrified cascade of Hamman-Meekhatin, Algeria.

the strenuous duty of the police force. As it often is necessary for the surgeon to get at the head of his patients as they lie in the stretchers, a forward side entrance is provided. As a patrol wagon, the capacity of the vehicle is a "squad," or eight men, not counting the driver's seat and the one beside it. When occasion demands, the seats on only one side can be let down and one of the stretchers placed in position on its spring supports.

### Conduits for the Hydro-electric Plant at Gatun Dam

THE Panama Canal is to be electrically operated and lighted throughout by power which will be generated at a hydro-electric plant located at the spillway to the Gatun Dam. At present two steam-electric stations exist, one at Gatun and the other at Miraflores, each consisting of three 1,500 K V A., 2-phase, 25-cycle, 220-volt steam turbo-driven generators. The power station at Miraflores will be retained permanently as a substitute or auxiliary station in case of breakdown or over emergency, but a new power station now being built at Gatun will be of sufficient capacity to furnish the necessary power for the whole canal. The hydraulic plant will consist of three 2,500 K V A. 2-phase 25-cycle 220-volt water-wheel driven units with sufficient provision for three additional units. The power will be utilized in the operation of the electric towing locomotives which will haul ships through the various locks, operating the lock gates, and lighting the whole canal. Ultimately, part of the power of this plant will be used for the electric operation of the Panama Canal Railroad. The illustration herewith presented shows the conduits through which the surplus waters of the lake that are turned through the plant will be conducted.

### A Two Thousand-Pound Sunfish

ONE of the largest and most astonishing marine wonders seen for some time has recently been brought to light from ocean depths. This is a remarkable specimen of a giant sunfish shown in the accompanying photograph. This huge monster measures 10 1/2 feet from tip of its fin to tip of its snout and is 9 feet long. It weighs nearly 2,000 pounds. The great fish was captured in the Pacific Ocean off the California coast and the skin has just been mounted in New York for museum exhibition. The tremendous size of this denizen of the deep can be seen from the figure of the man standing near the head. Such huge monsters are rare, however, though some weighing from five hundred to eight hundred pounds have been obtained occasionally. They are to be seen in tropical and temperate seas, both in America and other countries. While inhabiting the open sea, at great depths, they are frequently to be seen off the California and Florida coasts. The skin has a brilliant silvery appearance and at night is said to be highly phosphorescent. The flesh, however, is not used for food. The big fish has comparatively a small mouth, and to provide for the enormous stomach consumes thousands of small fish and various other marine creatures. The great fish are three feet long, and when swimming the upper fin protrudes high out of the water. From certain ridges and folds developed on the body it is thought the monster is about fifty years old. One of the striking features, next to the colossal size, is the peculiar shape of the body, which looks as if the hind portion had been bitten off by some other formidable ocean inhabitant and left only a fringe of a tail.

### Street Car Ambulances

AMBULANCES of all kinds and descriptions have been in use for many years past, but not until the present time have there been manufactured a necessary means for the transportation of hospital cases.

(Continued on page 924.)

### Head Cooling Apparatus

THE man pictured in the accompanying photograph is not a hot-headed individual undergoing treatment to allay the angry passions, as one might suppose upon reading the caption. He is merely wearing a cooling coil designed by a Vienna doctor as a physical aid to medical treatment. Modern advances in these practices have scientifically established and widely extended the utility of various methods of treatment. Immense numbers might be instances since the inventor in which in one form or another the application of heating or cooling agents to certain parts of the body constitutes the most effective remedy that is at the disposal of the physician and surgeon. Pain may in the majority of cases be alleviated or even entirely suppressed by the judicious application of heat or cold. Similarly ice bags are used for this purpose. But the patient has to endure the weight of the bag with its load of ice and ice water. Whereas in the construction here shown all the weight he carries is the small coil of tubing which is quite flexible and easily fitted to the head. The supply of ice-water is siphoned down through the tubing from an elevated reservoir and is slowly discharged into a receptacle. The rate of flow is controlled by a suitable valve on the discharge pipe. The tube is of rubber, wound with aluminum wire, so that it is extremely flexible and will maintain any set position. Similar cooling devices are provided for other parts of the body.

### Combined Ambulance and Patrol Wagon

THE city of Dayton, O., which has several other large cities in the United States where the manufacture of automobiles centers, rapidly is replacing horse-drawn municipal vehicles with more modern and more efficient automobiles. Recently has taken delivery of an unusual type of combined ambulance and patrol wagon which has several interesting constructional features. It is shown by the accompanying illustration the photograph having been taken during a demonstration of the vehicle's adaptability to the city needs.

When the vehicle is used as a patrol wagon the light canvas stretchers which serve for ambulances are carried on large hooks up near the roof one of them can be seen in the picture. Other wise, which means when they are in use to convey injured persons to the hospital they are carried in spring supports that extend over folding down out of the way when the side doors are folded up for

# Inventions New and Interesting

Simple Patent Law; Patent Office News, Notes on Trademarks

**Preparing for the Post-fuel Age**  
**A**LTHOUGH coal was mined in New England as early as the thirteenth century, it is only during the past hundred years or so that any very heavy drain has been made on our fuel stores, and already despite the shortness of the period we have found that they are not limitless, but are fast being exhausted. No matter how economical we may be all our coal stores will eventually be consumed, and then we shall have to return to the power we use long before the steam age. Already we are making extensive use of water power or "white coal" as it is called, and determined efforts are being made to produce electrical energy from wind power. The tide has yielded us some power and so have the waves, and a considerable measure of success has attended the experiments with the production of power directly from the sun which by the way, is the source of the power in our coal, our rivers, the wind the waves, and to a large extent the tide.

It is interesting to see what inventors have been doing toward the conquest of the future. Herewith are a few typical cases picked out at random from hundreds of patents. We have selected no water power engine or motor for the reason that hydraulic power may be considered well past the experimental stage (one would suppose that wind power would also be in this class. Quite apart from the problem of storing the energy there has been much inventive activity in the design of the wind wheel itself). One of the principal objects appears to be to provide automatic means for reefing the wind wheel sails so as to prevent wrecking of the machine in a storm. Another object is to design the wheel so that it does not have to turn or swing into the wind but will operate with equal efficiency with the wind blowing upon it from any direction although the wheel itself revolves on a fixed axis. Such a wind wheel is shown in Fig. 1. The wheel is in the form of a vertical drum so that it will be revolved by wind from any point of the compass. To assist the vertical drum a pair of turbines are mounted on a horizontal axis above the main drum, and these are connected with a vane in the usual way to bring them into the wind. Fig. 2 shows a very ambitious design. The wind wheel is of mammoth size and provided with a huge disk vane to direct it into the wind. The entire structure is mounted to rotate on a turntable.

The motor shown in Fig. 3 is adapted to be operated by the tide. It will be observed that as the float is lifted from the position shown in full line to that shown by dotted lines, a pair of toothed sectors will be moved in opposite directions as indicated by the arrows and act upon pistons which transmit power to a power shaft. In considering this invention it is well to refer to a problem sometimes given to first year men in Stevens Institute. The problem is to figure out the amount of work done by the tide in raising a giant ocean liner from ebb to flood tide. Take a huge vessel say nine hundred feet long and ninety five feet beam, weighing 50,000 tons. In New York the tide rises about four and one half feet. One might suppose that it would take an enormous power to raise such a craft as this. But one is apt to overlook the time element. It takes the tide six hours to do the work, so that it actually expends less than 34 horse-power.

Inventors are apt to forget the amount of surface the float must cover in order to give them a power that is commercially worth while. And yet it is possible to use the tide commercially, in

fact it has been used for a long time in certain favorable locations. The prime requisite is a large reservoir into which the rising tide can flow and a narrow passage for the water. Power may then be obtained from current wheels placed in the stream of water. Fig. 4 illustrates a tide mill located in such a favorable position. On one side of the mill is the

Fig. 3—The tide slowly rotates the sector driving the power shaft.

Fig. 4—Mill operated by a stream from a tidal reservoir.

Fig. 5—Wave motor operated by oscillating floats.

reservoir on the other the open water. Owing to the difference of level on opposite sides of the mill, the water will flow in the direction of the arrow against an underfoot wheel, thus producing rotary motion. Gates are operated to reverse the conditions when the tide turns. The water will then flow in the opposite direction and operate a second underfoot

Fig. 6—Paddle wheels propelled by the surf.

Fig. 7—A "surf wagon" that operates a compressed air system.

Fig. 8—Surf dashing into the cells drives compressed air into a reservoir.

Fig. 9—Utilizing a sun-backed roof to generate power.

Fig. 10—Combined sun and fuel heated boiler for an ammonia engine.

wheel. Of course with a system of this sort there must be long periods when no power is generated because there is practically no difference of head in the water on opposite sides of the mill. The tide motor has the advantage that it can be placed in a protected bay and hence is not subject to destruction in storms as are the ordinary wave motors.

Fig. 5 shows a wave motor which may be anchored out at sea and which will communicate power to electric cables to land. It consists of a series of floats connected by rocking arms. The heaving of the waves causes the floats to move up and down with respect to one another, rocking the arms to which pump pistons are connected and so as the floats are rocked the pistons operate to pump water or air into a reservoir. If the reservoir is filled with air it may by means of a compressed air motor drive a dynamo which will generate current that may be sent to land through a cable where the power may be utilized in any desired way.

Most of the wave motors, so-called, are really surf motors (that is they depend upon an actual horizontal thrust of the water). Quite an elaborate surf motor is shown in Fig. 6. It consists of a series of paddle wheels mounted on floats so that they will rise and fall with the waves and keep the paddles constantly submerged to a predetermined depth. Then as the waves rush back and forth they will cause the paddle wheels to revolve producing rotary motion which is communicated through suitable gearing to air pumps. Another type of surf motor is shown in Fig. 7. It consists of a series of large waves or plates mounted on a long, broad wheeled vehicle which is arranged to be driven by the surf up the beach (rafts are attached to the vehicle connecting it with suitable mechanism on land). One of the rollers, however, passes around a pulley anchored out in the water. When the vehicle is driven up the beach it raises a weight which makes in carrying the vehicle back with the receding waves. This reciprocating motion of the vehicle operates an air pump that stores the energy in a compressed air reservoir.

Another scheme for utilizing the power of the surf is shown in Fig. 8. It is adapted to be built along a rocky coast. It consists of a many-celled concrete structure firmly anchored in the rocks. As the waves dash into the open cells they compress the air contained therein and force it through pipes to a reservoir. Automatic valves on the pipes prevent the return of the air from the reservoir into the cells.

Although the heat of the sun has been utilized to raise water to the boiling point and even to produce steam, certain engineers some inventors have thought it better to utilize a fluid that is more readily vaporized than is water. The apparatus shown in Fig. 9 employs an ammonia wheel (the wheel is situated in the heat of the sun beating upon the roof of a building). This vapor is automatically condensed by means of cold water after it passes through the engine and then is returned to the roof to be superheated again. Thus a closed cycle is maintained converting the heat of the sun into power. A similar apparatus for utilizing solar heat is shown in Fig. 10. Instead of applying the heat of the sun directly upon motor fluid it is concentrated by a reflector upon a body of water which will be suitably heated thereby filling a reservoir with water warm enough to vaporize the fluid used in the pump or motor system. This apparatus employs in addition to the solar water heater, a furnace which may be used on dull and cloudy days when the

# Tire bill payers!

You have demanded a vise-like rim-grip - with no cutting or breaking above the rim-and here it is

## Diamond

Vitalized Rubber

{ No  
Cinch } Tires

with Perfect 3-Point Rim Contact

Cross Section Diamond Safety Tread Tire

It's the *rim* as much as the *road* that wears out your tires. So we said to our engineers: "You must build us a tire with perfect 3-point rim contact."

*They did*—and now we offer you a sane, sensible, No-Cinch tire that will appeal to you, as a hard-headed, shrewd tire buyer—a man who insists on easy riding comfort and good liberal mileage.

Each point of rim contact in a tire is a point of support. Where the points of contact are not perfect, undue pressure is brought to bear at an unsupported point of the tire.

Then what happens?

The result is a terrific strain on the tire that will cause rim troubles, breaking above the bead and separation of the tread from the carcass.

All this is overcome in the "Diamond" because the three points of rim contact are absolutely *mechanically perfect*—the annealed steel cabled wire bead holds with a vise-like rim-grip.

This is only one Diamond advantage.

You get additional More Mileage without extra expense in the Diamond *Vitalized Rubber*—a scientific combination of pure, lusty, young rubber and a secret toughening compound—nothing inferior in rubber, fabric or workmanship—the No-Pinch Safety Flap inner tube protector—and, if you desire, the now famous Safety (Squegee) Tread.

**So this time buy Diamond Vitalized Rubber Tires—  
you can get them to fit your rims at any of the**

**25,000 Diamond Dealers**  
always at your Service

The superiority of Diamond Tires becomes manifest when the tire is used for a long time and the tread is still in good condition. The tire is made of the best materials and is built to last. It is the only tire that is built to last. It is the only tire that is built to last. It is the only tire that is built to last.

## Pure Air Anywhere All Summer

Yes—even in that back room or basement so stifling last summer that you gave it up as unusable during the hot weather.

### Sturtevant Ventilating Fans

solve any ventilating problem no matter how difficult. They force out all the bad air and blow in a cool, steady stream of fresh air from outdoors.

The Popular Type Fans are for use where you have volumes of air to be handled without pipes. They are usually placed in top part of window or in wall or partition, and force the bad air out doors or to another room. The portable fans, in fact, are used in bedrooms, bath rooms, hall rooms and work rooms.

Model No. A.P.-4 describes these Fans

Sturtevant Ready-to-Run Ventilating Fans are such small units that they may be removed or supplied as a distance through piping. They are used in ventilating and cooling various kinds of rooms, basements, closets, show rooms, etc. They are also used in taking away odors and fumes in factories, laboratories, etc.

Model No. A.P.-4 describes these Fans

Don't wait until hot weather comes again. **ACT NOW.**

Write us about your ventilating problem. Tell us whether you want to drive the fan by belt or electricity. Tell us what electric current you have—volts, cycles, phase, etc. Give us the size and location of your room. Our nearest engineer will advise you without cost to you. We can provide you with the proper fan to fit your exact needs.

### Legal Notes

**Court of Appeals Decisions.**—Out of sixteen patent appeals in which decisions were handed down by the Court of Appeals for the District of Columbia on December 30th, 1910, the decision of the Commissioner of Patents was reversed in only two cases. In one of them, that of Perri against Thoma, the decision of the Commissioner was reversed, and priority as to all claims awarded Perri. The other case in which the Commissioner's decision was reversed is that of Broune v. Dyson, in which priority was awarded to Broune.

**Some Adjudicated Patents.**—Patent No. 709,718 for a dumping wagon has been held void for lack of patentable invention in *Leonhardt v. Lynch*, 100 F. 700, while the Bronsken patent No. 739,824 for a union protector has been held valid and infringed in *Fisher Manufacturing Company v. Lawrence*, 100 F. 709. The Towne patent No. 848,140 for a steering wheel for auto vehicles has been held void on its face for lack of invention in *Thorne Tearing Wheel Company v. Lee*, 100 F. 777. The Jordan patent No. 892,084 for apartment wall furniture has been held not infringed in *Marshall & Bowers Company v. Murphy Manufacturing Company*, 100 F. 772, and the Andrews patent No. 897,513 for a toaster has been held valid and infringed in *Andrews Wire & Iron Works v. Wilson Manufacturing Company*, 100 F. 708.

**Some Adjudicated Patents.**—In *A. R. Mace & Co. v. Lums*, 20 Fed. Rep. 453, it has been held that the Canfield patent, No. 612,701, for an igniter for gas, oil or vapor engines, is valid but not infringed, in *Thoe J. Rly Manufacturing Company v. Frisbie*, 230 Fed. Rep. 424, it has been held that the Hoffman patent, No. 671,136, for a mop wringer, is valid and infringed, the Latham patent, No. 707,534, for a projecting kitescope, has been construed and held not infringed in *Motion Pictures Patents Company v. Independent Moving Pictures Company of America*, 200 Fed. Rep. 411, it has been held in *Rued Manufacturing Company v. Pittsburgh Water Heater Company*, 200 Fed. Rep. 440, that the Rued patent, No. 761,406, for a gas burner, was construed and held not infringed and that the Rued patent, No. 875,518, for a gas burner, was void for invention and that the Rued patent, No. 903,007, for a water heater, was held valid and infringed, and in *Williams Patent Crusher and Pulverizer Company v. Kinney Manufacturing Company*, 200 Fed. Rep. 441, it has been held that the Williams patent, No. 938,775, for an improvement in pulverizers, is not void on its face for lack of invention.

**Court Decides Against the Taggart Dental Inlay Patent.**—Much interest is taken by dentists in the decision of the Court of Appeals of the District of Columbia, filed the Taggart patent, No. 879,978, of December 3rd, 1907, upon a divisional application filed July 14th, 1907, of original application filed January 10th, 1907. This decision, the opinion in which was rendered by Mr. Justice Robb, reverses the decision of the Supreme Court of the District of Columbia, which decision sustained the Taggart patent. Defense was made that the invention had prior to Dr. Taggart's invention been taught, used and operated, at least two years before the filing of the Taggart application for patent. The Court said that it was fully persuaded that the evidence shows beyond a reasonable doubt that for many years prior to the filing of the application for patent the process of making patterns and molds for dental inlays and the like, as expressed in the claims, had been publicly practiced upon many occasions and that it was of no possible consequence that by the use of Dr. Taggart's machine, gold inlays and the like might be produced more cheaply and rapidly than they were produced by dentists who had settled in the case. The Court goes on to say that the art of producing metal castings by means of a mold formed of a wax pattern is very old, was practiced by the ancient Greeks and Romans, extensively used in the middle ages for producing statuary and is known to this day under the name of "lost wax" process.

If you could buy a barrel of anything which would increase the light in your factory 19 to 36 per cent, wouldn't you seriously consider the purchase?

You would figure at once the value of that extra illumination, in reduced lighting bills and increased efficiency of employees—and then ask the price of the barrel

That is a fanciful way of putting our proposition, but it is all fact, nevertheless 19 to 36 per cent actual increase in light (depending on the present condition of your ceilings and walls) is what you will gain, if you paint the interior of your factory with

## RICE'S MILL WHITE

Rice's Mill White is an oil paint, not a cold water mixture. It gives you a glossy tile-like surface which captures every ray of light entering the room and reflects it down on to your machinery and into previously dark corners of your plant.

Read what the Kellogg Toasted Corn Flake Company write us

Stattle Creek Mich Feb 26th 1912

Dear Sirs:

Before using your product our factory was painted with cold water paint, which constantly collected dust and dirt, thus becoming almost or solid in places, in places to wash off. After several coats had been applied the surface was clean.

The sanitary conditions of our plant have been improved, and the dust and dirt does not readily adhere to the surface which can be washed and kept very clean.

From general appearance we should judge that you are getting about 50 per cent more light than was formerly obtained before Rice's Mill White was applied.

Yours truly

KELOGG TOASTED CORN FLAKE CO.

Rice's is the original "Mill White" paint. No other paint manufacturer can use the Rice process. No imitation has the lasting qualities of Rice's Mill White Paint.

Rice's Mill White Paint is sold direct from our factory in barrels containing sufficient paint to cover 20,000 square feet, one coat. If you have that area of ceiling and wall space to cover, Write for Booklet and Sample Board.

Ask for a copy of our booklet, "More Light" Write today

### RICE'S GRANOLITH

A tough and elastic permanent finish for concrete walls. Becomes a part of the concrete to which it is applied. One coat sufficient to make glass as desired. Makes the best possible primer on inside concrete and brick for a second coat of Rice's Mill White Paint, giving a tile-like enamel finish at no more expense than lead and oil paint.

For Concrete Surfaces

# PROGRESS

Our wonderful nation is an ever-growing, ever-progressing one. We have planned, we have dug, we have plowed, we have built, we have mined, we have made and we have sold. We have neither inherited our wealth nor have we laid tribute upon weaker nations. But behold! We are the richest of them all.

Such a progress—the spirit that has made this nation the leader of nations.

Progress demanded something to replace "Old Dobbin," and American genius replied with the first crude automobile. This evolved into the modern motor car, powerful and massive—its very hugeness making it swifter and sturdier, endangering life. So Progress demanded a safe-guard. Came the often-made, quiet metal stud, and the first far-from-satisfactory rubber knobs. And Progress called once more.

Then was invented the Republic Staggard Tire, the tire that gave a real protection against skidding, an all-to-be-desired lively control, and a much-increased mileage—truly The Tire Perfect.

And Progress looked, and was pleased.

## Trade-mark Notes

**A Trade-mark Decision.**—In the case of ex parte United Hoarding and Manufacturing Company Mr. Commissioner Moore has decided that the word "Lakewood" was held improperly and refused registration on the ground that it is a geographical term. In his decision the Commissioner called attention to the fact that there are sixteen or seventeen post offices in the United States called Lakewood, but none of these are well known places and the Commissioner says that he cannot agree with the holding of the examiner that it is probable that an ordinary person would regard Lakewood as a geographical term but believe that the word would be regarded as fanciful by a large majority of observers and therefore decides the mark to be registrable.

**Trade-mark Oppositions.**—In The Irish Industrial Development Association v. Barrett, the Commissioner of Patents following a number of cases, such as Lang v. Green River Distilling Company, Natural Food Company v. Williams, and Johnsonville Company v. American Steam Packing Company, has held that it is not necessary in order to sustain an opposition that it should appear that the opposer is entitled to register the mark, but that it is sufficient that the mark should have been used in some manner analogous to trade-mark use and that the opposer has such an interest therein that he would sustain or be likely to sustain actual damage by the registration of the trade-mark by another.

**Copied a Trade-mark in China.**—The Shanghai Daily News tells how, at the mixed court in Shanghai, which has jurisdiction over Chinese residents, a Chinaman, Tai Yun-shan, was charged with selling goods to which a false trade-mark had been applied, the false trade-mark being that certain boxes containing soap manufactured and sold by the Chang Hing Wo Ku Company (Lau) bore the name and stamp in English of soap manufactured by W. Goswami, for which Mr. C. R. Burdell is the local agent. Mr. Burdell stated that he saw the boxes of soap on a barrow, and recognizing the trade-mark had the man detained by the police. His firm were the sole agents for the manufacture, a denial of the trade-mark was found in the factory, and there were 214 boxes of soap there bearing the trade-mark. The defendant was fined \$100, and the court ordered that the boxes already stamped with the trade-mark be confiscated. Had we some such summary punishment for trade-mark infringement, in this country, there would be less trade-mark piracy.

**A Peculiar Trade-mark Condition.**—In a recent decision by the Commissioner of Patents, it appeared that a registration certificate was issued in 1908 to "The American Rolling Mill Co. of Middletown, Ohio, a corporation organized under the laws of the State of Ohio" upon an application purporting to be filed by such company. Later application was made "The American Rolling Mill Company" for the cancellation of the registration, which application stated that the registrant company is a corporation organized under the laws of the State of New Jersey and under the laws of no other State and that the statement that the company was organized under the laws of Ohio was an error due to accident, inadvertence and mistake. After due proceedings an order was duly entered by the Commissioner of Patents canceling the registration. An application was filed by "The American Rolling Mill Company" a corporation duly organized under the laws of the State of New Jersey and located and doing business in Middletown, Butler County, Ohio, for the registration of the same mark and the Examiner of Trade-marks has refused registration on the last application in view of several registrations. The petitioner then sought to have the original registration registration relinquished. In denying such petition, the Commissioner suggests that it does not appear that the petition could obtain any legitimate benefit from such a registration, that it is believed the Commissioner had ample warrant for canceling the registration, but that he has no authority to restate and registration to a non-existing application.

## Why build your factory roof more than two inches thick?

Concrete roofs are admittedly the highest grade of fireproof roofs. Their great weight and resulting high cost have been the only objections urged against them. Were it not for these two factors the concrete roof would be now—as it is destined to be in the future—the universal fireproof roof.

With Self-Sentering you can build a strong, light, concrete roof two inches thick. You can build it without form work or centering of any kind. You can easily and economically build roofs of any character—pitched, domed, saw tooth or gutter—as well as flat roofs.

Self-Sentering is a new form of expanded metal concrete reinforcement and general fireproofing. It is a combined reinforcing and centering—a one piece steel mesh and stud.

Self-Sentering comes in sheets 28" wide and up to 12' long. It can be curved in the factory to any desired radius. It is adaptable for practically all classes of concrete construction.

Send for the Fireproofing Hand Book. It contains a list of references in regard to how to construct concrete, with many diagrams and illustrations.

near Mafin of the Lavin mines in France made some observations on this subject. While mine tunnels were being put through, or shortly after, he noticed some movements of the ground which cannot always be accounted for by the simple weight of overlying earth. Certain places

showed an abnormal pressure at various levels under ground, and at other points he found very great pressures at small depths, and on the contrary low pressures at great depths. Considering various observations, he is led to believe in a latent pressure in rock strata.

### The Problem of the World's Oil Supply

Consuming the Product of Ages in a Year

IN view of the importance of the many industries which rely upon oil as fuel, the question of the possible exhaustion of the world's oil supply deserves the gravest consideration. There is every indication that we are face to face with this possibility. In the oil districts themselves the cost of crude oil has so risen that in the Russian, American, Roumanian and Persian fields record prices are being obtained. It may be remembered that a short time ago a vessel endeavoring to obtain heavy oil in New York had to pay \$12 a ton, which is about the price at which it can be obtained in England. It may be that the present high cost of oil is partly due to financial jugglery, but on the whole there can be little doubt that it is chiefly due to a real shortage in the world's supply.

Prof. Lewis, lecturing before the Royal Society of Arts in England on the subject of Liquid Fuel said that as long ago as 1886, when the Russian oil fields were in their zenith and flooding 2,000,000 barrels of oil to such an extent that the barrels were of more value than the oil itself, Prof. Leslie, one of the greatest authorities on the subject, addressing the oil mining experts in Pittsburgh, said in the heart of that country, but it is them in the clearest possible way that the enormous floods of oil they were getting must of necessity soon come to an end. "It is clear," he said, "that in the laboratory of nature you can only have oil held forward at about one ten thousandth or millionth the rate at which it is being consumed, and inasmuch as the strata contain only a certain quantity of oil, the tremendous output will mean that these oil fields will only be gleaming with difficulty the drops we have left behind." Of course conditions of this kind cannot be expected to influence in any way business men, but Prof. Leslie's words have proved to be absolutely true as regards that field, which was the first to show signs of exhaustion, and at the present moment in that district, which yields these floods of oil, only barrels are now obtained where the yield was hundreds of tons. The Baker Field, too is showing signs of exhaustion. The Texas fields have been opened up, and supply is rising, and also the California fields, these give the supplies to America. As for the whole world's production, although it has been doubled within the last ten years, this result has only been obtained by the multiplication of wells not twice, but twenty fold, and by the opening up of new oil fields. But in spite of this, it would seem that the supply cannot keep pace with the demand. There is no indication that the present high prices will be lowered. They may even increase. Meanwhile the oil consumption of the world is growing at an enormous pace. Gasoline, which a quarter of a century ago was regarded almost as a waste product, is now in such great demand that in England alone, which consumes only one thirtieth of the total oil supply of the world, the consumption has doubled during the last four years, eighty million gallons having been used in 1912.

In these circumstances, therefore, the problem of finding substitutes for the kinds of oil in greatest demand becomes of the first importance. Gasoline, which is a light oil, is at present the most important, and the general oil shortage is chiefly felt as it affects the supply of gasoline. These considerations have led to the establishment of a Petrol Committee by the Royal Automobile Club, and representing practically every known national transportation. The first report was published in December, 1912, and was devoted

entirely to the problem of transport and handling generally with due consideration of the restrictions existing as to storage, and the result may be summed up in the statement that the committee arrived at the conclusion that even if the restrictions were reduced and transport cheapened, gasoline might, and probably would, remain equally dear. The second report, published very recently, considers possible substitutes for gasoline. So far it has devoted its attention to one viz., benzole. Benzole as used in the trade under the name of 80 per cent benzole consists of three pure products: benzene, toluene and xylene. All these are hydrocarbons but the proportions of hydrogen and carbon are different in the three compounds, and they have different boiling points and consequently different freezing points. It is the lower freezing points of the toluene and xylene which are so valuable as the benzole alone that is pure benzene, freezes at so high a temperature that it would be useless for use for motor use. It is not altogether impossible on many occasions.

The proportions in which the three components are found in 90 per cent benzole are given as 70 per cent to 75 per cent benzene, 24 per cent to 25 per cent toluene, and about 1 per cent xylene. The term 90 per cent benzole is entirely a trade name and is an indication of the purity of the benzole. It merely implies that the mixture of the toluene and xylene is such that 90 per cent of the mixture will distill over below 100 degrees Cent. Pure benzene would be disadvantageous, not only because of its tendency to freeze in the winter but also because the gasoline power would be less. It has been found experimentally that the presence of toluene means considerably more power on the hills. There are usually a number of impurities in benzole, but this can be readily obtained in a very efficient washing.

If the washing and final rectification be carefully done, the quantity of impurities remaining in the benzole ought to cause no trouble whatever.

The committee found that not only could benzole be used as an effective substitute for gasoline, but that it was even more efficient. There was a 10 per cent increase in mileage obtained by the use of benzole, this is only to be expected. The whole question is one of calorific value per pound of fuel. Assuming petrol (gasoline) to have a calorific value of 10,500 British thermal units per pound, and 80 per cent benzole to have a calorific value of 20,000 British thermal units per pound, and taking petrol (gasoline) at 8.5 pounds per gallon and benzole at 8.8 pounds per gallon, this gives benzole an advantage of 20 per cent in calorific value over petrol per gallon, hence the increased mileage.

As against the optimism of this part of the report we must set the facts that the present supply of benzole is so small that it stands no chance of rivaling gasoline, and that no visible way is yet available as to what are the true commercial possibilities of increasing the supply of benzole. It must not be forgotten that the production of benzole from coal involves cooking about half a ton of coal to get a gallon of benzole. And if benzole is to take the place of gasoline it must be produced by the millions of gallons, which means that a market must be found for the corresponding millions of tons of coke. These are questions which have yet to be investigated, and it is hoped that with the publication of the third report of the Petrol Committee we shall know exactly where we stand.

## I'M GOING "EVINRUDE"

WHEN dictionaries become more complete, more people will know that "Evinrude" means gliding through the water at an eight mile pace preferably as the major pleasure of an auto trip. The

which carries like a stitch and weighs but fifty pounds, fits into my auto without inconvenience to the passengers. It attaches to my motor in less than one minute, by means of two large thumb screws and its wheelless propeller will drive a rowboat, filled with people, to anywhere you wish to go. It is two full horse power, simple to operate and starts with a swing of the fly wheel. No cranking. If comes, if desired, in a c'mis case, so that it may be carried on trains, street cars or other conveyances without trouble. A large illustrated catalog will be sent upon request.

## Time, Mileage and Upkeep

These are the factors—time, mileage and cost of upkeep—which are settling this automobile question. We are confident of being on the right side of the settlement.

For buyers of today are looking up the records of cars not over five and six years ago.

Even the first Chalmers cars, many of them with records of 50,000 to 100,000 miles, are still in daily use. Ask the owners about Chalmers quality.

Among the 15,000 owners of Chalmers cars a great many are driving their third or fourth Chalmers. Men don't buy a second time a car which is costly to maintain, which is unreliable in any respect.

The service which Chalmers can have given their owners for the past five years has helped us to build up a factory of seventeen buildings, which represents an investment of \$6,000,000.

It has enabled us to increase our business not sensationally, but steadily—from year to year. We think our factory equipment, our organization, and the goodwill of our customers give us the right to believe we can continue to progress this year, next year and many years to come.

The man who bought a car last year or the year before from a company which is not now in business is probably not an altogether happy man.

Chalmers "Thirty-Six" at \$1950, Chalmers "Six," five-passenger, \$2400, and seven-passenger, \$2600 (fully equipped, f o b Detroit) are truly "all you can ask in a motor car."

They are good now; they will still be good five years from now. Many are being sold each day and the remainder of this year's output will not last very much longer. You should order now.

Chalmers Motor Company, Detroit, Mich.

## Summary of the Seventh Annual Report of the Carnegie Foundation for the Advancement of Teaching

THE seventh annual report of the president and treasurer of the Carnegie Foundation which has just appeared, covers the 3 years ended September 30th, 1914. The report of the president, like the former reports, is divided into two parts—the first referring to the current business of the year and dealing with questions more directly pertaining to the administration of the foundation, the second part being devoted to current educational matters of a larger and more general nature.

The first part of the report includes a careful statement of the whole question of pensions for teachers, for government employees, and for industrial employees. This statement contains the results of the examination of practically all of the pension systems now in operation anywhere and leads finally to a discussion of a feasible pension system for the public school teachers of a State. As the report points out the bills which have been introduced in the various legislatures almost without exception violate fundamental actuarial conditions and have been framed without study of the essential conditions which must be fulfilled in any adequate pension system. The material brought together in this report the examples of the failures of pension systems which have occurred as, for example that in New South Wales and the previous situation in which many State pension systems now stand, make this portion of the report one of great practical value to the authorities of any State contemplating pension either for teachers or for State employees.

President Hutchins in extending finally for some form of contributory pension system for public school teachers points out clearly the difficulties of the contributory system, the necessity for the most careful actuarial study, and the public nature of the question which are involved in a distribution of the cost of such a pension system between the State and the teacher. Following the discussion of these points is a complete history of the methods by which the Carnegie Foundation pension were arrived at in given the process in the frank manner, the difficulties which this encountered and the differences which arose out of the fact that the pensions of the Carnegie Foundation are not contributory, but have come as the result of a free gift are made clear. The literature on pensions now at the disposal of the Foundation is probably the most complete in the statement of such problems that has ever been brought together and the discussion here made cannot fail to be of value to a college, a State or an industrial association which is studying the pension problem and the pension problem today is one of the most important problems of modern social progress.

The second part of the report is devoted to such subjects as the matter of college entrance requirements, admission to advanced standing, a statement of medical progress, university and college financial reporting, advertising as a factor in education, education and politics, and finally, about universities.

All of these subjects are discussed in the frank and specific manner which has hitherto been used in these reports. In recounting the extraordinary medical progress of the last five years attention is called to the competition which still exists in the United States between reputable colleges and unworthy medical schools. The focus of the recent litigation on medical education in Europe are also brought clearly forward. During the last five years the mortality among unworthy medical schools has been most satisfactory. The number of such schools in the United States has been reduced by about one third and the number of students attending them by about one quarter, and this diminution has occurred in exactly the places where it ought to

**Wood-Working Machinery**

For the purpose of the wood-working industry, the most complete and up-to-date machinery is available. Also in all makes of Automobile and Light Truck Tires. The purpose of this journal is to record accurately, simply, and interestingly, the world's progress in scientific knowledge and industrial achievement.

## A Problem of National Proportions

THE floods in the upper watershed of the Ohio, with their tragic accompaniment of suffering and widespread ruin, will have carried with them a large consolation if they prove to this nation that the question of the control of the Mississippi River and its tributaries is broader than any State or community and that it must be faced and mastered by the nation at large.

Anyone who asks why the Federal Government should be urged to take hold of this problem on a national scale and assume full responsibility for the time and labor and great cost involved in obtaining complete control of the Mississippi River, surely it is sufficient to remind him that the drainage basin of this great river covers forty-one per cent of the total area of the United States. A line delimiting the frontiers of this area starts on the Louisiana coastline, sweeps westerly through Texas, and then northwesterly through New Mexico, Colorado, Wyoming, Idaho, and Montana, swings across the Canadian border line, to re-enter the United States in North Dakota, then passes on its coastward bearing through South Dakota, Minnesota, Wisconsin, northern Illinois, northern Indiana, Michigan, Ohio, and even swings into New York before it reaches on its southerly bearing through Pennsylvania, Virginia, North Carolina, Georgia, and Alabama and finally reaches the Gulf again through Mississippi and Louisiana.

If we except the arid regions, every square mile of this vast territory contributes its quota, be it large or small, to those floods which, with periodic regularity, overflow the twenty million acres of land which lie between the Gulf and the Gulf.

There is to be no question of floods, such as that which a few weeks ago devastated the upper valleys of Ohio, and is today threatening the lower regions of the Ohio and the Mississippi, are comparatively local in their origin and effect, but this merely points the moral that any adequate treatment of this stupendous problem must be based upon the broadest kind of survey of the whole situation, in which every possible agency which may be contributory to disaster is included.

The drainage basin of the Mississippi River covers 1,340,000 square miles, and of this total the Missouri basin covers 827,150 square miles, the Ohio basin 201,700 square miles, the Arkansas basin 190,000 square miles, and the upper Mississippi basin, lying above the junction with the Tennessee, 130,000 square miles. In the Red Basin are 60,000 square miles and the Central Valley lying between the Missouri River and the Gulf of Mexico, covers 60,000 square miles. Although the Missouri basin is by far the largest, it is comparatively a dry region, and the rainfall is scanty. The Ohio basin constitutes the zone of heavy precipitation and although in area it is less than half as great as the Missouri basin it contributes about three times as much water to the Mississippi River during the year. Moreover, there is to be no wide difference in the various basins between the rainfall and the run-off. The Missouri basin, for instance, where the soil is sandy and highly absorbent, and the winds are dry, delivers a much smaller percentage of its rainfall to the main river than does the surface of

the Ohio Valley. Thus the Missouri has an annual rainfall of 50.4 inches and a run-off into the river of but 12 per cent of this. Of the annual rainfall of 84.7 inches the upper Mississippi delivers but 27 per cent to the river. The Ohio basin, on the other hand, with an annual rainfall of 48 inches, delivers 30 per cent of this to the river.

It will be readily understood from the above comparison that if the losses in the lower regions of the river are to be ameliorated in their work of keeping the flood within the banks by a system of reservoirs at the headwaters, the most promising field for investigation is in the upper reaches of the Ohio, and its tributaries. It is, of course, doubtful if any system of control of this kind could cope with such a four days' rainfall as caused the recent floods, but it might greatly mitigate disaster, and it is for the Federal Government to undertake immediately the necessary surveys to determine what can be done along these lines.

That the rapid denudation of our forests has increased the total volume and the speed of the run-off into the river during heavy rains cannot be questioned. This suggests that any movement for Federal action should receive the hearty co-operation of the powerful interests which are working for forest preservation and for the reforestation of denuded lands. Also, if the Government investigation should show that reforestation construction would materially assist in Ohio and Mississippi flood prevention, the Reclamation Service should prove to be a powerful factor in the new movement. Furthermore, this would be the time to draw up legislation with regard to the conservation and control by the Nation of its water powers.

If ever there was a great National undertaking which called for intelligent co-operation and thorough organization, it is to be found in the control of our greatest river.

Above all, Congress should avoid hasty and ill-considered action. The problem should be considered from the broadest national standpoint; and the final plan should be agreed upon, only after this great question has been viewed from every possible standpoint and submitted to the highest technical investigation.

Finally, whatever may be done, let it never be forgotten that by far the most important and pressing obligation is the completion as early as is physically possible of a levee system to insure the Mississippi throughout the full length of the rivers affected.

## The Thousand-foot Ship

NOT very many years ago, that distinguished naval architect, the late Sir William White, surprised the world by stating that if the conditions of transatlantic traffic called for a 1,000-foot ship, he would be perfectly practicable to build and operate a vessel of that size. Few of us at that time dreamed that there would ever be a call for such a huge vessel, yet so rapid has been the development of transatlantic travel, and so industries have been the "Ade" and harbor communities on both sides of the Atlantic, that not only is accommodation in the way of channels and piers being made ready for such a ship, but thanks to the enterprise of the steamship companies, the 1,000-foot ship is within sight. The launch of the "Vaterland" (formerly known as the "Europa") for the Hamburg American Line has carried the transatlantic liner up to within fifty feet of the thousand foot limit suggested by Sir William White as the remotest possibility. If we remember rightly, his statement was that the line of the appearance of the White Star liner "Oceanic," the first ship to exceed the length of the "Great Eastern" (802 feet) and the first to exceed the limit of 700 feet. Since her appearance the progression has been rapid. She was followed by the "Admiral" which carried over all the indicators to 760 feet, the "Oceanic," 862½ feet, then by the "Imperator," 920 feet, and now by this 980-foot ship. A third vessel is building upon the docks at Middlesbrough. She is to be larger than the "Vaterland," and if her length is increased only by the freedom of the "Vaterland" at her stern, this ship will have the distinction of being the first 1,000-foot vessel.

Frequently the question is asked, what is the limit of practicability? How big will be the liner of tomorrow? It is not clear that the answer is very far from the physical limitations are those only of the depth of our entrance channels and the length of our harbor piers. Judged from the economic standpoint, from the point of view of revenue earning for the steamship line, the limit of practicability is not very far from the transatlantic liners to ever increasing size, provided of course that the speed be maintained without reasonable limit. It may be broadly stated that for the larger ships, the less the cost of carrying a given number of passengers and a given tonnage of freight. The same principles which have led our railroads to build 50-ton cars and 800-ton locomotives encourage our shipbuilders to produce vessels 1,000 feet or more in length.

## Why We Need an Aerial Navy

EVER since the record 31-hour flight of the new German Zeppelin airship on October 20th, 1910, the military world has been asking the question: Why do we need an aerial navy? The answer, as we have seen, is that the Zeppelin, the British military authorities have been greatly startled. At about 1 A. M., on the morning of October 20th, 1910, a large dirigible was seen over Rheims, the military outpost near the mouth of the river Tennesse. The airship is known to have traveled to the island of Heligoland, in the North Sea, and thence along the German coast, after which it crested back to Berlin. Notwithstanding that the weather was foggy, the captain had an extra lining capacity of two tons available for ammunition. As there is no longer any doubt about the havoc that can be wrought by bombs dropped from aeroplanes and airships, the British War Office has greatly alarmed by the reported appearance of this airship, and England's Ministry of War has set to work in earnest effort to secure a suitable air fleet for the Island Kingdom.

The descent, on April 3rd, after a flight of some seven hours from Friedrichshaven, of the latest German "Zeppelin," a rigid dirigible, at Lorient, France, as a result of its becoming lost in the clouds at a height of some 10,000 feet, affords further proof how easy it is for an airship to start in one country and land in another.

The announcement of a prize of \$50,000 by the *Los Angeles Daily Mail* for the crowding of the Atlantic in an aeroplane within 72 hours has brought to the attention of the American public the possibility that a modern Zeppelin might cross the ocean and attack this country in the time of war. The latest Zeppelin airships with four motors are credited with a speed of 60 miles an hour in still air, and if one of these reached the altitude in which a favorable wind was found, it could probably cut several hours off this time. This would mean that after crossing the ocean and attacking this country, the airship could attack cities such as Portland, Me., or Boston, Mass., and return across the Atlantic without replenishment of fuel. It would be an easy matter, however, to have wireless communication with the airship and carry the necessary supplies of fuel and ammunition. It would be well for Congress to consider whether it would not be wise to undertake the construction of a dirigible of large size for experimental work, and make a generous appropriation for an up-to-date aeroplane fleet. During the last five years Germany, France and Russia have built 28,000,000, 2,200,000, and 312,000 in the order named for aeroplanes. Italy, Austria, and England have spent eight, five, and three millions, Belgium, two, Japan, one and one half, and Spain, 600,000, whereas the United States of America, only \$400,000 has been expended and we have to day less than a score of aeroplanes and one out-of-date dirigible, as against the large and efficient fleets owned, respectively, by France and Germany.

## Potash Fertilizer and Frost

EXPERIMENTS made in France by W. Götts show that potash fertilizers have the property of protecting crops against damage from frost. In order to show what results are obtained in different cases be proceeds as follows: Three areas of a quarter of an acre each were sown with rye. The first area did not receive any fertilizer, and on the second and third there was applied 200 and 180 pounds, respectively, of the fertilizer known as "kainite." After a period of heavy frosts it was found that the ground of the area which was strongly fertilized had not been frozen. The second or less fertilized area was much less frozen than the unfertilized field. The author considers that this effect is no doubt due to the saline solution at the surface of the soil. However, he thinks that the sprouts on the unfertilized area were less frost-tolerant than the others, and the leaves seemed to have lost a considerable percentage of water by plasmolysis. But during the thawing period, the pathological symptoms disappeared and the plants showed a rapid and vigorous growth. On the other hand, the effect of the frost was shown by a yellowing of the leaves. As is known, the damage caused by freezing is due to the fact that the water contained in the tissues of the plants expands when the ice is formed. The action due to the frost is shown by a yellowing of the leaves from the plant, and thus has the effect of de-

## Engineering

**The Lonsborough Railroad Completed.**—By this time trains should be running over the Lonsborough railroad, which joins Berne with Brigg, the last rail having been laid on the 28th of February. This road opens a new highway between the north and south of Europe by way of the Lonsborough and Blacktun tunnels across the central Alps. By the new route the distance from Calais to Milan will be 675 miles, which is shorter by eighty miles than any existing route.

**A Recent Spring Test.**—During the course of some recent tests of locomotive spring steel made of vanadium steel, a four-stranded 105,000-pound chrome-silicon steel as the elastic limit was developed. This, as far as our knowledge goes, constitutes a record for locomotive spring steel. Carbon, oil-tempered springs showed an elastic limit of 101,000 pounds; chrome-silicon, spring-tempered springs, an elastic limit of 134,500 pounds, and the chrome-vanadium oil-tempered springs showed a limit of 286,000 pounds.

**Boatbuilding with Four-man Turbels.**—Multiple-gun turbines are certainly the favor just now, for the French authorities have decided to adopt four guns in each turret for their four ships of the "Normandie" class, which are to be laid down this year. These are three turbines, one forward, one amidships just abaft the funnels, and one aft. The four guns in each turret are 574 feet long, 87 feet 7 inches bore, and displace 25,200 tons on a 28-foot 4-inch draft. The armament consists of twelve 14-inch guns and twenty-four 5.5-inch guns. The armor belt is 12½ inches in thickness.

**Panama Canal to be Inspected.**—As a result of the visit of the members of the House Naval Affairs Committee to Guantanamo, Cuba, and Panama, it would seem that the members are in favor of rendering the canal impregnable, and placing a garrison at Panama of sufficient force to prevent a hostile force from making any attack upon the canal throughout its entire length. Col. Goethals stated before the House Military Committee last January that a garrison of 25,000 men would be needed for the purpose. This is a large force, but when we consider the magnitude of the interests involved, it does not seem to be excessive.

**Satisfactory Solution of a City Nuisance.**—The successful introduction of electric traction in the suburban service of railroads, as exemplified in the electrification of the New York Central and New Haven railroads, has led to the formulating of a proposal for electrifying the New York Central freight lines from the northern end of the city to the 72nd Street. This will give to the New York Central Railroad a better service, and will solve the problem of the smoke and noise nuisance which is occasioned by the present open tracks of the railroad along the shoreline of Riverside Park. The Board of Estimate of this city has arranged with the New York Central Railroad to place its tracks in a subway, the surface of which will be formed into a broad driveway, the space between the tracks and the drive being turned over to the city to be laid out as a part of the Riverside Park system. The tracks will be operated electrically.

**Continued Sliding at Calaca, Cal.**—On the night of March 12th to 13th the break in the east bank of the canal, opposite Calaca, which first moved its bank on the night of February 5th, again made another rapid movement downward and toward the canal. The bottom of the canal, according to the Canal Board, is now heaved up to a level one thousand three hundred feet, to a maximum vertical height of about thirty feet, destroying five tracks in the bottom of the canal, and leaving only one track in commission. The canal engineers are not damaged, and they have already placed steam shovels at work removing this material. Later when the water is turned into this section of the cut, the two new floating dredges will be placed in service and they will remove material at the rate of one million three hundred thousand cubic yards per month.

**Columbus and the Panama Canal.**—It is stated that the three models of Columbus's ships, built in Spain and sailed here and exhibited at the World's Fair at Chicago in 1893, are to be exhibited at the World's Bazaar Exhibition in 1915. If the ships are carried out, the little craft will leave Chicago, pass down the Mississippi, through the Gulf of Mexico, and so through the Panama Canal up to San Francisco. There is some question as to whether the ships are to be taken in the search for a westward passage to India that Columbus set out on his classic voyage. Of the last of his life voyages, he reached the isthmus of Panama, and his ships were commended at Colon. The vessels that the journey over the Panama Canal and the Gulf of Mexico and up to the western coast of San Francisco, however, suggesting that they have been forced upon a westward passage to India.

## Aeronautics

**\$50,000 for a Trans-Atlantic Aeroplane Flight.**—The *London Daily Mail* has just made an offer of \$50,000 for the first aeroplane which shall fly across the Atlantic Ocean in either direction in 72 hours time. The flight must be made between England or Ireland or from any point in the United States, Canada or Newfoundland. This prize is intended to be awarded to the first of all aviators throughout the world. It is permissible to alight upon the water and take on more fuel if this can be arranged for. About a year ago there was a great deal of discussion regarding the trans-Atlantic flight, but it has been so long since that we believe that the flight will be made, if not this year, at least in the summer of 1916. Such manufacturers as Hildebrand, Herl, Humber, and Col. Cody have already announced their intention of competing for this prize.

**A \$25,000 Prize for British Aeroplane Constructors.**—The *Daily Mail* has also offered \$25,000 for the first aviator who shall fly across England, Scotland and Wales and as far as Ireland, that is, within one mile of Kingston, London, in 72 consecutive hours. The machines are not allowed to descend upon land at any point, but they may stop in harbors for fuel replenishment. They are to be hydro-aeroplanes or flying boats and not land machines. This prize is offered by British constructors and aviators only. These two prizes are the first big ones that have been offered for several years to promote progress in aviation. The Gold prize of \$15,000 offered in this country three years ago had but one serious contestant, when it was thought that it was to be held but was not. This prize was offered for a two-motor aeroplane, the type of machine which will undoubtedly be needed to accomplish the trans-Atlantic flight just mentioned.

**Record Flight with a Passenger on the Pacific Coast.**—On Sunday, March 22d, a fast flight was made from Los Angeles to San Diego, Cal., by W. L. Bonney with his Deperdussin monoplane, carrying Miss Margaret Stahl as passenger. The start was made from Los Angeles at 1:30 P. M., and the flight continued for an hour and eight minutes. Bonney alighted at Oceanside. He started from this place at 3:16, and finally landed to the south of San Diego, at 3:56 P. M. He had adverse weather conditions to contend with on the coast, but he was not troubled. The flight took place because of a number of bonfires that were lighted in the vicinity. He was supposed to land beside a huge bonfire at San Diego. As a result of his confusion, he landed and broke the machine. The flight took 1 hour and 108 minutes for the 112 miles between Los Angeles and San Diego makes his average speed for the flight 62.22 miles an hour.

**Record Cross-country Flights in Germany and the United States.**—By a strange coincidence, army men in Germany and the United States have recently made lengthy cross-country flights and broken all records. On the 30th ult. Lieutenant von Cramm and Bohmer, starting from Jüterbog, near Potsdam, flew across Berlin and Lubek and as far as Cism in Sollowien-Holstein. They were in the air 6 hours and 9 minutes and covered a distance of 373 miles, thus averaging 60 miles an hour. On March 20th, Lieut. Milling and Nibmeyer of the Signal Corps Aero Squadron No. 1 flew from Texas City, Texas, to San Antonio, a distance of 287 miles, in 3 hours and 20 minutes, or at an average speed of 71 miles an hour. Upon arriving at the latter city, they remained aloft for another hour, making a total duration record of 4 hours and 20 minutes. Two days later they flew back to Texas City against a strong wind in 3 hours 50 minutes. They used the new Burgess tractor biplane fitted with a 70 H. P. Hault main engine. The German and American flights are new records for cross-country flights with a passenger.

**\$77,000 for a German Aerial Fleet.**—The latest plan of the German Admiralty for a huge aerial fleet to accompany the warships have recently been made public. The call for an expenditure of \$77,000,000 is to be spent during the next five years, while the appropriation for army aviation and aeronautics is to be \$20,000,000. In a bill introduced into the Reichstag on March 24th, a large appropriation was made for the naval dirigible, balloon, dirigible, airship, etc., eight of which are to be put in service and two to be held in reserve. To house these dirigibles, fifty-four double revolving balloon sheds are to be constructed. With this new type of shed the dirigibles can be housed at any time, as matter what the weather. Extra sheds are to be built as a reserve. Fifty aeroplanes (thirty-six for active use and fourteen for reserve) are to be built and are to be manned by a special corps. The German navy is to have a special corps for the fleet of aeroplanes and dirigibles to be spread over the years 1916 to 1918 amount to \$8,700,000 for dirigibles and \$25,000,000 for aeroplanes, while \$1,500,000,000 is added for guns, the aeroplanes, and the dirigibles. The life of these new dirigibles is estimated at four years.

## Automobiles

**A Automobile Lamp Trimmer's Wagon.**—We have become familiar with the wagon having a high towable frame, run by battery or electric power, and with lights. Patent No. 1,065,080 is for a lamp trimmer's wagon having an electric motor and controlling means extending into position to permit of its operation from the top of the lamp or trimmer's structure.

**New Motor Fire Engine for Use in Dardanelles.**—A new motor fire engine recently has been delivered to the city of Dardanelles, Germany, and under test an unusual capacity was demonstrated. The apparatus is self-propelled by means of a gasoline motor which, at 1,200 revolutions a minute, drives a pump which is connected to a four-stage centrifugal pump which at approximately 1,700 revolutions a minute yields as much as 500 gallons of water against a head of 800 feet. With nozzles measuring 40 millimeters in diameter it jets of upward of 104 feet in height were obtained, the manometer pressure being 15 atmospheres.

**An Automobile that Pulls itself Out of Holes.**—In a patent, No. 1,064,831, to Gay Victor De Ivel of Crocker, S. D., there is shown a draft appliance for automobiles, in which a winch is detachably secured to the hub of the rear wheel or wheels connected to it and led forward through a friction guide carried on the forward portion of the automobile with the front end of the rope anchored at a suitable distance in advance of the wheel. The winch may be operated by a man to wind up on the drum and draw the automobile forward the machine being suitably guided on the rope by the forward friction guide.

**Cooling Pneumatic Automobile Tires.**—Andrew B. Crug of Tramo, Mo., has secured two patents No. 1,049,077 and No. 1,049,078, wherein the pneumatic tire is cooled by suitable means which operate to secure a circulation of the cooling medium through the tire. The cooling liquid which may be salt water in summer or alcohol in winter, is circulated by a pump operated from the wheel during an accelerated motion and through a cooling tube in the tire in such manner as to maintain a sufficiently low temperature to prevent overheating the tire thus preventing blow-outs likely to result from the overheating and consequent expansion of the air in the tire.

**Commercial Vehicles in Munich.**—The city of Munich is putting in service a number of power wagons for transporting wounded persons. Such wagons can also carry a number of patients. The platform is to take in the horse, the platform is swung out from the back end so as to run down upon the ground. The horse is strapped onto this platform and the whole is run into the van by the use of a motor-driven winch. Means are provided for conveying the horse onto the platform from the street in the best way. The new motor vans are fitted with 30 horse-power gasoline or benzol engines and have single rubber-tired wheels in front and double in the rear.

**The Four-tractor-wheel Type in France.**—A new type of power wagon is making its appearance in France this being the tractor having all four wheels driven from the motor and acting as steering wheels. Besides the Renault wagon in which we referred the Blum-Louis and the Renaults are now ones of like principle. The well-known Renault works are engaged on the same subject, it is said. It will be remembered that this firm supplied a great part of the automobiles in Paris, with the De Dion company. If speedsters of this type are really in use of a good tractor for use with a trailer car or a train of cars. Most of the present power wagons, which are excellent are designed mostly for separate use with the engine in front and wheels are in extensive use in the army as substituted power wagons. It is even proposed to hold a separate course for new tractors, quite outside of the regular annual military power wagon endurance test, so as to compare the tractor among themselves.

**Gasoline in War.**—Commander Ferns considers that the fuel question for automobiles and especially for power wagons is a vital point for the French army, as a large amount of gasoline needs to be imported from the United States. The German army has 25,000,000 to 50,000,000 gallons of gasoline furnishing a large part. Home production of fuel is denied, but this is a difficult matter. Among the fuels, benzol has only a limited production, and each country is likely to absorb its own product. The German army produces 200,000 tons of benzol and at the same time consumes 700,000 tons of gasoline. France produces but 10,000 tons and this is not enough even for the automobiles in Paris, which need 18,000 tons. It is a home product but it is dear and the price fluctuates. The French army chemists are occupied with new products, but we must wait for those. Petroleum or heavy oil, however, seems to have a good future should inventors be able to produce it in quantities as in the Diesel engine. Schist oil is extensively found in France, and there is a good outlook in this direction.

### Fireproof Shelter for Refugees

#### Receipts

IT is very evident that the empty garbages and attics may be quite as great a menace as the full one, if not properly cleaned and sterilized. And hence the storage of the rubbish at times a matter of vital importance. Closely associated with garbage disposal is that of ashes and waste paper. While it does not present a sanitary menace, such refuse matter is dangerous in reason of the fires that it may cause.

The task even of all this refuse matter and the receptacles in which it is contained an excellent suggestion has been made in Mrs. Flora Speidelberg. She proposes that fireproof rooms should be made in the cellar or basement of the building, to receive the garbage and ash cans. It is essential that such a room be well ventilated. A terra cotta wall, metal doors and windows for ventilation are practically all that is necessary. Of course such a room should have easy access to the street. Where there is no basement or where the basement is used for storage, a shelter should be built at the back of the building, such as illustrated in the accompanying drawing. The ideal shelter should contain a metal box for papers and also a place for washing the cans after they have been emptied. This idea has been approved by the Health and the Fire Commissioners of New York City and of the Chief of the Fire Prevention Bureau. Such shelters, if required by the building code, would do away with fires that are now of common occurrence, due to smoking of paper, crockery, rags, and other materials near elevator shafts and under wooden stairways.

Mrs. Speidelberg points to the fact that similar conditions exist under open iron gratings in front of many shops. In front of garbage receptacles containing all soaked rags are frequently left standing without any cover or open gratings under which gasoline is stored, and often wooden boxes and barrels are placed beneath all soaked rags and papers. Added to the danger of open incense combustion is that of the lighter match, cigar or cigarette carelessly thrown into the fire trap.

### The Smokestack and the Rudder of the "Imperator"

IT is difficult to convey an adequate impression of the size of a huge modern Atlantic Ocean liner by means of photographs or drawings. A more phenomenon does not tell the story unless there is some object alongside that may be used as a basis of comparison and even then it is difficult to grasp the full dimensions of the vessel for the reason that the object with which it is compared must necessarily be enormously large so large in fact that it itself must be compared with a smaller object more within our ken. A better method is to dissect the ship and show certain details of it as compared with smaller and more familiar objects. In the accompanying illustration we show a section of one of the smokestacks of the new giant liner "Imperator." The smokestack is elliptical in section and the major axis of the ellipse is thirty feet long. The stack would form a tunnel of ample dimensions for a locomotive and train to pass through. Standing beside the section of the funnel is a man who is completely dwarfed by the bulky steel cylinder. The smokestack of the "Imperator" will extend sixty nine feet above the deck. Sixty nine feet is the height of an ordinary six-story house. The rudder of the Imperator weighs ninety tons, and the stack on which it swings weighs 110 tons. Despite its enormous weight the rudder will be moved at the delicate touch of a wheel on the bridge nearly a sixth of a mile away. The "Imperator" will have a total length of 919 feet. Her sister ship the Vaterland just launched, 880 feet long. A complete description of this vessel will be found in the current *Illustrated*.

#### Circasian Walnut

CIRCULAR 212, entitled "Circasian Walnut," is the fifth number of a new

Fireproof room for garbage and ash cans and waste paper.

series admirably promising to supply a void in the library of the young farmer, as well as in that of the wood user. It is a very interesting and important contribution to the history of the use of one of the best known woods in the world. The subject is discussed in the following chapters: Common names, uses, in fire and cultivated range, sources of supply, logging and transportation to market, waste in preparing logs for shipment, consumption of Circasian walnut in the United States, growth characters of the wood, minute characters of the wood, substitutes for Circasian walnut.

The trade name of this wood is Circasian walnut.

A section of the huge smokestack of the "Imperator."

Handling the 90-ton rudder on the "Imperator."

so called because it comes principally from Circasia, which lies between the Black Sea on the southwest and the river Kuban on the north. It is not generally known that this tree is the same as the English walnut, the fruit of which is found in every market. It is now one of the most widely distributed of the commercial timber trees. There is no authentic record as to when Circasian walnut was brought into the United States. Here it has been planted from the Atlantic to the Pacific, the greatest attention having been given to it on the Pacific Coast where it is grown for its nuts. Since wherever it is grown in the United States it is for this purpose, the wood produced is of little importance.

The Circasian walnut is remarkable not only because its wood is so attractive and valuable that the best grades often bring a higher price than mahogany, but because it grows to a considerable size, and attains a great age. An English writer relates that the architect Bannockburn saw a table made of a single piece from the trunk of a walnut, which was 26 feet in breadth, and of a proper length and thickness. It was upon this board that the Emperor Frederick III had a splendid entertainment in 1724. The age of the tree was estimated to be about 900 years.

Referring to the logging and transportation of this wood and the waste in preparing it for market, this circular points out the alarming extent to which Circasian walnut is approaching exhaustion. It informs the reader that the supply is often very limited, and, in fact, invariably fails to meet the demand. Realizing the importance of a home supply, France passed an act in 1720 prohibiting the exportation of Circasian walnut. In consequence, large numbers of plantations were established throughout England, France, and Germany. Some of these were very extensive, one founded in 1818 near Boulogne, France, contained about 30,000 trees. Nothing new is given in reference to the gross structure and mechanical properties of the wood, but the old facts are presented in language which the layman will easily understand. Another chapter is devoted to a consideration of the structure and composition of the wood, but it is purely elementary and singularly free from technicalities. Substitutes for this wood are also dealt with and the reader cautioned to guard against spurious kinds which now masquerade in the market as Circasian walnut.

#### Urban's Researches

IN his report upon the work of Prof. G. Urban of the Paris University, who recently obtained the La Caze prize awarded by the Academy of Sciences, M. Le Chatelier sums up the main points of these researches upon the rare earths, and mentions a number of new elements discovered in this way. During the course of his researches to find the rare elements M. Urban made more than 100,000 fractional crystallizations. We wish to bring out the new elements which he found in this way, or at least, definitely established. He first isolated the metal cerium in a pure state and showed its real existence, it being identified with bodies described by Crookes and Loiseau de Rohaudou, whose somewhat different properties were due to impurities. Next he established that gadolinium, which Demarcay had obtained in a pure state, is the same as the ytterbium of Crookes, this latter having quantities of yttrium with it. The atomic weight of gadolinium is now fixed at 157.2. M. Urban then produced lanthanum in the pure state, and its atomic weight is 138.2. He identifies it with elements sought by others, which Crookes called lanthan and neodimium. All doubts upon these various points are now cleared up. Next, the metal dysprosium is identified with bodies mentioned by Demarcay, Crookes and others, and its atomic weight is 162.6. The most brilliant piece of work done by M. Urban was to show that what was called ytterbium is in reality made up of three bodies which are no doubt simple elements, these new metals being neodymium, samarium weight 137, indium (Yb), and more recently the element cerium.

## Safeguarding Machinery at Hawthorne

How an Electric Company Protects Its Shop Employees from Injury

Fig. 1.—A punch press fitted with a guard which will swing down in front of the die space when clutch rod is operated by the treadle. Position of guard is shown before treadle is pressed and while work is being put in machine.

THE present workers in the field of manufacturing industry are witnessing one of the most rapid periods of evolution in the history of mechanical appliances.

Occasionally, no doubt by present-day competition and by the constant demand for cost reductions, engineering skill is now being concentrated upon the production of highly efficient equipment, tools specialized to particular classes of work, and devices of many kinds designed to perform work which is difficult of execution by an operator.

One of the most important results of this general change through which the art of manufacture is passing is the occupational adjustment demanded of the workmen. Manual adjustment demanded of the workman. Manual operations, which have become familiar often by years of execution are changed to the supervision and working of machines adapted to perform these operations more quickly and accurately. These manual operations were not without their associated dangers, but the dangers were thoroughly recognized, and the experience of the workmen provided the safeguards. Machinery, however, introduced new hazards for which experience had no safeguard.

Unfortunately, the evolution from manual to mechanical operations has been so rapid that the designers and manufacturers of modern machines, tools, and appliances have been forced to devote too much attention to the demand for higher speeds, greater power and lower cost, and until recently have given too little

Fig. 2.—Stationary guards for protecting the complicated parts in a heavy press for forming the housings of metal subscriber sets.

Fig. 4.—View of a method of safeguarding a wood working machine

Fig. 3.—View of a punch press fitted with a guard which swings down in front of the die space when the clutch rod is operated by means of the treadle. The position of the guard is shown after the treadle has been pressed and machine operated.

attention to the safety of the machine operators, to whom such increase in speed or power or each addition of new mechanism introduces new and unfamiliar risks to be guarded against. The manufacture of machine tools today is giving this feature due consideration in the design of his product and in most cases moving parts of machine tools, such as gears, fly wheels, and pulleys, are adequately protected from accidental contact.

The machines in the manufacturing department of this electric company in Hawthorne Ill. have always been given careful consideration so that they might be equipped with the necessary devices to protect those who come in contact with them. In addition to the actual precautions which have been observed, a systematic campaign has been carried on during the past two years to reduce to a minimum the risk of injury in operating the machinery. During this period a group of from six to twelve men have devoted their entire time to fitting up machines with special safe guards. This work includes not only the covering of dangerous moving parts with guards but also design for the assembled tools so as to prevent accidents.

To offset the conditions which introduce hazards, careful analyses have been made of all situations which might be the cause of accidents, and wherever possible these conditions have been counteracted. The following are some of the more important. All belt shifters, switches or other devices controlling the operation of

Fig. 5.—A circular saw woodworking machine with guard over belt to keep the latter clear and a guard over the saw. The second guard prevents injury to the hands and the wood from coming together at the edge, jumping up and snapping the operator.

Fig. 6 shows a vertical spindle molder or "slicer" for woodworking with guard over cutter to prevent injury to hands. The machine grooves wood and all saw-dust is removed by means of an exhaust system to which a hand is connected.

Fig. 7.—In this view the picture shows a multiple spindle drill press provided with sheet metal doors (A) in front of spindle driving shafts (B) to prevent them from flying out in case they become disconnected at the universal joints (C).

machines are located within easy reach of the operator, so that he may start or stop the machine without moving from his position while at work. In all operations which are injurious to the eyes, such as the dressing of emery wheels, goggles are furnished to be worn while the work is being done. It is an established fact that lighting conditions are responsible for a large number of accidents, and very careful consideration has, therefore, been given to the proper illumination both of the departments and of the individual machines.

guards are provided to protect moving parts of machines which project in such a way as to be a source of danger, to protect belts or chains driving machines from motors on the machines or on the floors, and also belts driving machines from countershafts to pulleys located on shafts to protect all gears, to protect cutters in metal working or wood working machines, such as milling cutters, circular, band, and jig saws, and wood shaper cutters, and to protect emery and polishing wheels.

Some idea of the extent to which this work has progressed is obtained from the report of the Telephone Apparatus Shop at Hawthorne for the past year. A total of 1 077 guards of all types was installed comprising 353 guards for covering gears 300 for covering belts, 108 for protecting milling machine cutters, 105 on hand shield guards on automatic spool winding machines, and 411 examples of a miscellaneous nature.

machines, and 411 appliances of a miscellaneous nature. The guards are generally of three kinds: stationary guards for idle gears, and other exposed moving parts; adjustable guards for saws and cutters of various types; and mechanically operated guards for use on punch presses. Aside from these are the various tools and feeding devices designed for the protection of the workman's hands while operating the different machines.

A better idea of the diversity of the hazards in introduced by modern machinery, as well as the extent to which this humanitarian electric company has attempted to remove all dangerous elements, may be had by studying the illustrations shown of these types of guards. Fig. 2, which shows a stationary guard, has been selected to illustrate the complicated design of moving parts in one of the heavy presses for forming the housings of metal subscriber sets. In this case all moving parts into which the operator might slip, or be drawn by his clothing, are well protected. The guards, moreover, are so designed and located that they will in no way interfere with the operation of the machine at its highest efficiency.

Fig. 5 illustrates a typical adjustable guard applied to a circular saw. This is, perhaps, one of the most difficult problems encountered, inasmuch as it depends for its success upon the co-operation of the workmen. Guards of this type must be adjusted to suit the work being done.

A good example of a mechanically operated guard is shown in Fig. 1 which represents a gate applied to a punch press, which is closed before the downwardward stroke of the ram rendering it impossible for the operator to be in position before the treadle is pressed. In other cases, where the nature of the work is such that a guard of this description cannot be used, pressure rollers have been equipped with tools through which the sticks are fed, and the rollers are so arranged that the sticks can be placed under the punch. In other cases flat feeders are employed, putting the work in proper position and advancing it under the operating part of the machine. The same results are obtained by sliding dies, and by means of a special arrangement of rollers. The guard is in proper position before the treadle has been pressed and the machine operated. Fig. 6 represents a spiral molder or slicer. Fig. 7 and 8 illustrate a drill press and a lathe, a method of guarding the operator from the rotating parts.

During the past year the company has spent about \$25,000 in designing and installing these protective devices. That the work has been done efficiently is proved by the fact that the Department of Factory Inspection of the State of Illinois has requested that we demonstrate our methods to other manufacturers as a guide to similar work. The Industrial Commission of the State of Wisconsin has also solicited information regarding the safety devices in use at Hawthorne, to employ in its campaign to provide for the safety of employees in manufacturing plants in that State.

## A Scientific Investigation of Pianoforte Touch

At a recent meeting of the Physical Society Prof G. H. Bryan read a paper on "The Dynamics of Planetary Tumb" which should prove of much interest to at least three classes of people. The subject has in the first place a purely scientific interest; secondly, the makers of mechanical piano players should find in the researches carried out by Prof. Bryan most valuable indications of the direction in which they must move

to improve the mechanism, however perfect it is even at the present day, of the mechanical piano player, and thirdly, the subject is one which appeals to every pianist.

There is a common impression that it is hopeless ever to expect the piano player to fully reproduce the touch of the virtuoso. While Prof. Fryan does not go so far as to positively assert that this impression is erroneous, he does insist that it should not be accepted without proof or test, and he has proceeded to carry out experiments to investigate just what is meant by 'touch' and whether it is capable of being reproduced to a greater extent than hitherto upon pneumatically controlled pianos.

The question turns very largely on the extent, it is said, to which the *quality* of individual notes can be varied by striking the notes in different ways. Such a possibility involves the inferences that (a) the intensionality of the fundamental tone and its several harmonics are capable of independent variation, (b) these variations can only be produced by varying the behavior of the pianoforte hammer while it is in contact with the string for example, by lengthening or shortening the duration of contact, (c) such an effect can only be produced by rapid time variations of the pressure applied to the keys, (d) these variations of pressure are due to fairly rapid decreases or increases of pressure produced by smartly striking or heavily pressing on the key.

The author describes experiments, which appear to indicate beyond all reasonable doubt the existence of such effects of "touch," and which certainly demonstrate the possibility of reproducing them by means of the modern pneumatic<sup>1</sup> instrument. For this purpose the author's piano-player, which is a first-class instrument of standard type, but with a specially selected hammer flange, is connected with a specially constructed auxiliary lever<sup>2</sup> for which a patent application has been filed. This lever operates directly on the face of the auxiliary regulating bellows, and the alteration in the bellows can be regulated to produce a desired weight placed on the key, or by applying hand pressure to the lever itself. In this way the touch of the piano is varied in the same manner as the touch of the piano. So far as the experiments of the author indicate that even if the lever is worked in conjunction with suitable expression marks, no could be done by a person of moderate experience increased breadth of contrast is obtained, while by varying the position of the lever independently of the pedaling, a variety of effects can be obtained, which can further be increased, by hand pressure.

A short sharp pressure produces a bright ringing trouble with a light base, a sustained pressure produces a rich base with a soft trouble, the general character of the tone being suitably described as "metallic" in the first case and "woody" in the second. A very complex use of these features of the instrument is the marked differentiation which they show between notes in different parts of the scale, especially in chords, the notes of which are accurately rung (as is unfortunately often not the case in music rolls). The duration of the pressure required to produce the maximum effect on a particular note of the piano varies continuously from the trouble to the base end, being least in the trouble and greatest in the base. The same is true of the dynamical differentiation notes in a particular part of a chord at any part of the scale can be accented independently of the rest.

Whether it is possible to vary the quality of individual notes is a point that can only be tested by playing single notes as opposed to chords. The difference can be as effected can only be noticed by a trained ear, in the same manner as the difference in the quality of the notes of a piano and a violin. The difference is very slight differences, others no differences at all. The differences are probably as conspicuous as those between a stopped string and a harmonic on the violin. It is not always easy to produce these differences for purposes of demonstration, though it is different in the case of the piano. The differences are not noticeable composition in any case the author finds that the effects can be obtained more easily with a pneumatic player fitted with an auxiliary lever than in striking the keys with fingers. When the lever is disconnected the change observed affords some indication of the difference in the quality of the notes in the imitation of the organally played wind.

### "Sitting Dharmas" and Hunger Strikes

As has been pointed out by a correspondent of the *London Times*, the hunger strikes of the English suffragists represent the revival of a very old and widespread custom, known in the East as *dharka* (or *tharak*, spelled as *tharak* in the original text).

This custom was once very common in India, but is now almost obsolete. It was chiefly resorted to in order to force payment of a debt. The debtor would

at the creditors' door and was no food, until his slaves were satisfied. If the debtor allowed the creditor to starve he was believed that he laid himself liable to supernatural punishment, especially if the starver happened to be a Brahmin; accordingly, Hindus of lower caste would sometimes engage a Brahmin to starve for them. The custom was much abused, being used to levy blackmail upon persons who were not debtors at all. It also gave rise to various analogous practices, e. g., that of certain beggars in the Punjab, known as "starch-diggers," who twist a leather strap around the neck and throw themselves on the ground, and roll about in the dirt, until they are satisfied in order to obtain compliance with some demand a person would threaten to commit suicide or to kill one of his own children unless his wish was granted. All such practices are forbidden by the Indian Penal Code.

An identical custom once prevailed in Ireland, and is frequently mentioned in the Breton laws. It is recorded that St. Patrick "fasted upon" Logmire, the hamthen over-king of Ireland, until the latter embraced Christianity, and in accordance with the superstitions of the time the king and his family felt it incumbent upon them to fast at the same time until this test of endurance was won by the saint.

## Vegetable Hair Industry of the South

**V**ORABLE hair or so called Spanish long or black moon is an epiphytic plant growing on a good many different kinds of trees in the southeastern United States, West Indies and South America. The plant has a mossy, tomentose growth on the bald, rounded, smooth, black, shining, warty, lobed, and known botanically as *Tillandsia usneoides*. The specific name *usneoides* means 'like *Usnea*,' a generic name of a gray lichen or so called 'moon' which is common along the coast as far north as New Jersey, and which is also common in the West Indies. The word 'moon' common under 'moon' is a misnomer for the plant, because it is not a moon at all, but belongs to the pine-apple family of plants (*Bromeliaceae*). While this plant grows upon another, it does so without deriving any nourishment from it, and is a parasite. It is more of the nature of an air plant, hanging in long festoons from the branches of the trees throughout the moist regions of the South. It is generally considered that it does not interfere with the growth of the tree on which it grows, except in cases where it is a very sturdy.

[illegible]

There are no data at hand to show the present annual production and consumption, but the value of the prepared vegetable hair in the South may safely be estimated at about \$200,000.

### The Current Supplement

**I**N the current issue of our SUPPLEMENT G. V. Fraumeni gives full directions for constructing a single phase induction model. Our readers interested in oncology will find this a most useful article on "Statistical models for epidemiologic data." Dr. D. O. Johnson, College of St. Francis, Chicago, is contributing to volume 12, Dr. Dariusz Swietnicki, University of Illinois, is contributing to volume 13, and Dr. J. H. Little, University of California, is contributing to volume 14. Dr. D. O. Johnson is contributing to volume 15 with his paper on "Statistical models with lipid drugs for oral hypoglycemic agents," which can be requested by any biologically interested person.—Fraumeni G. Palmer contributes a most important article on the highly beneficial effect produced on the skin by raising serum levels in relation to skin drugs.—The new giant molecule, "Platamid," which measures 500 feet in length and 100 feet in height, is described and described.

## Crews of American Ships

To the Editor of the SCIENTIFIC AMERICAN

In the SCIENTIFIC AMERICAN of March 30, 1913, page 223, I saw an article entitled "To Upbraid the Merchant Marine," by Charles Depeaux. I read the article with interest and with many valuable suggestions relating to our merchant marine in the domestic or foreign trade. I note, however, the following:

"Why the management of an American steamer is compelled by law to employ only American men, the man that may be employed to build American steamers may be of any and every nationality, is one of those things past finding out. Whatever the reason the facts are there, and they add to the handicap that the American merchant marine suffers from."

I have noticed this statement at different times in articles written by different persons relating to our American merchant marine. It is true that the licensed officers of vessels of American registry are required by law to be American citizens, but this is not true of the crew, and those writing about our American merchant marine should understand this. J. W. ALEXANDER  
Washington, D. C.

## "The Fallacy of the Spring Wheel"

To the Editor of the SCIENTIFIC AMERICAN

The above entitled article by G. F. Fisher appeared in your valuable paper February 1st, 1913. It would appear that the article might in some cases discourage attempts to find a substitute in the spring wheel for the pneumatic tire, and in the writer's opinion it is too early in the stage of development as yet to curb any such attempts.

The greatest drawback of the spring wheel is not so much the work required of the springs as the objectionable effect of inertia of the rim weight and other parts of the wheel before the spring action is reached. In the pneumatic tire we have already known of the inertia in the practical absence of inertia effect because of the comparatively small mass of the tire affected at any moment of the wheel turn, in other words, there is practically no weight in motion differing from the weight of the tire. Any weight of the tire, which results in the air weight being practically floating on an air cushion.

How different are the conditions with the spring wheel. Here we have a rim and tire weight as well as a portion of the spring mechanism of possibly fifty pounds at least, which weight is wholly to be considered as outside the wheel rim so that at any far speed the inertia of the mass and weight is a considerable quantity to raise and fall freely over the road obstacles at a rapid velocity, and in fact it is sufficient to rack a wheel to pieces.

To solve the spring-wheel problem attention should be directed toward placing all of the wheel weight possible inside of the springs and away from the rim or tire, which means that the springs must do their work as near the track as possible, and if they are capable of acting in one segment of the rim without affecting the balance of the rim or tire the effect will be so much nearer the ideal.

The writer believes a spring wheel will yet be produced that will compare with the pneumatic tire in weight, but working with hub springs and heavy rims must give way to development of peripheral springs displacing the least possible mass of the wheel rim to action.

Along these lines there is hope.

Oshkosh, Wis.

L. J. MORAHAN

## The Mississippi Problem

To the Editor of the SCIENTIFIC AMERICAN

I wish to congratulate you on having brought out so many ideas on the problem of the Mississippi, and more particularly to thank you for correcting me in the matter of the bed of the stream. Theory alone will make it clear to anyone that so long as the Gulf of Mexico remains open, no raising of the bed of the Mississippi can possibly occur, lower or higher. It is a real comfort to know that the lower Mississippi can really be controlled by the levees, and I am sure that many of your readers like myself feel that they owe you a debt of gratitude for having cleared their minds on this point.

However, I cannot but feel that your attitude on the problem as a whole is far from the correct one. It seems to me that you have misunderstood the real problem of the Mississippi with the present method of controlling its lower portion. For in your editorial you seem to have all but disregarded everything and everybody except St. Louis. I submit that the real problem is not the question of how to put sand water into the Gulf but of how to get the water to sea level and better look the question of man; and the question is not,

Can the flood waters be confined between levees? but instead, Can they or any portion of them be put to better use elsewhere?

You say that the trouble with the reservoir plan is the magnitude of the problem. But there remains a lurking feeling that if the flood water could be stored in volume, you would still favor the levee system as being sufficient, and it is certain that in case the floods were many times greater, your line of reasoning would force you to declare that much more emphatically against the levee system. At any rate, this does not look like a question of magnitude alone, but of principle as well. No one, I hope, favors the removal of the levees, but there is certainly much that can be said in favor of dealing with them by the reservoir plan.

First, common sense teaches that it is cheaper to build one dam across a river than to heighten two levees alongside of it, and also that a flood saved at the source of a river is a flood saved throughout its entire course. Second, the writer says that inasmuch as the cost of both levees and dams is roughly proportional to the square of their height, and the benefit in the case of the levees not in a greater proportion, while in the case of the dams they may by wise selection be made out of all proportion to the cost of the dam, it would be wise to at least give the dams a fair trial.

Third, the Almighty has pronounced in favor of the reservoir, as is so plainly evident in the case of the St. Lawrence, whose basin covers an area forty per cent of that of the Mississippi and yet whose steady outflow is less than nine per cent of the flood record of the Mississippi, a ratio of nearly five to one in favor of the reservoir plan.

Finally, the SCIENTIFIC AMERICAN itself admits that a reduction of three or four feet in the height of the floods could be secured by converting the St. Francis basin into a reservoir, and objects to the idea only because flood-still of Miami would be flooded. An objection well founded so far as the St. Francis basin is concerned but an objection that would become a mighty blessing almost anywhere west of Omaha.

And against all this you set up what authority? One Townsend. Under such awe-inspiring circumstances, one would feel impelled to ask with bated breath, "Who is this man Townsend?" were it not for the fact that his testimony comes to prove chiefly that he knows what he knows, while he knows nothing of your attitude.

Your attitude, Mr. Editor, seems to amount to this: The western man says, Give us the reservoirs. They will be a great blessing to us and a material help to the Southern planter and to river navigation." You reply, "Yes, they would help us a great deal, but the trouble is that they would help you so much and give you just what you want, namely, water area instead of parched land. Therefore we cannot think of such a thing." N. J. NORRIS  
Noble, Ala., Canada.

## Criticism of the Gear Engine

To the Editor of the SCIENTIFIC AMERICAN

I have been greatly benefited by reading your excellent journal for the greater part of my life. But I am surprised beyond adequate expression at the article "A New Gear Engine," on page 240 of the issue of March 15th. If I correctly understand the proposition, and I believe I do, Fig. 1 is a very old plan, in fact it is what started me on the turbine. Steam acts upon the device and rotates it in a very short time even if made of the best steam metal. But that is not the point I take exception to. It is the statement regarding the expansion, "the continuous flow against a series of pistons," "expansion in the turbine," "the turbine receiver." Now if any one can find an expansive element in the continuous flow of steam into an infinite receiver I am badly off my base, but I am more than willing to learn. Then on page 248 the second article states, "Of course the pressure energy of the steam instead of the kinetic energy." There is certainly no expansion possible in pressure energy, but under favorable mechanical conditions, "kinetic energy" can exert the limit of possible expansion. I only know of two kinds of practical confined steam expansion, viz., that beginning at the point of the cut-off in a reciprocating engine, and that secured by providing an increased diameter, or enlarged passage, as in the case of turbines. Of course the latter expansion would be the "infinite receiver," or more properly the exhaust. This is one of the very interesting problems that have appeared from time to time and I hope you will consider it worthy of space in your journal. GEORGE J. FANSHAW  
St. Louis, Mo.

## New Cycle of the Gear Engine

To the Editor of the SCIENTIFIC AMERICAN

I would like the privilege of replying through your column to the objection raised by Mr. Ferguson, in his letter which you kindly located to me, raised against your article on my gear engine. It will elucidate the

subject for the general reader if his letter is published together with this reply.

His misconception of the working of the engine may be due, it is possible, to the very cursory explanation of the invention which a limited space made necessary. On the other hand, it is possible that there are but two practical ways of using steam because he "knows" of no other is naïve, to say the least. My eyes, I am eager to admit, does not appear in any book on thermodynamics. But for what purpose do inventors invent if not to prove new theories and advance new methods?

His objection, in brief, are these: First the device is a "very old plan," second, the steam will exit the metal, and third, the steam cannot be obtained from steam at a continuous flow.

In reply to the first, I must say that the United States Patent Office differs radically in opinion with Mr. Ferguson upon the novelty of the invention, and has granted very broad claims on the very uniqueness of its construction and art. There are several drawings of gear engines in the Patent Office which look like this device, but in fact are very different.

My answer to the second contention is that thorough tests in actual service of my gear engine since 1907 have conclusively refuted any theory that the steam might exit the metal. The reason for this is a mechanically simple one, the surface of the gear travels through the center of the steam, and the steam is so close that it has absolutely no chance to flow steadily through any small clearance between the gears and center-piece wall, while in the case of a slide valve, the steam will exit the metal because there is so little motion in the parts. It must be remembered that the surface of any high-speed rotor does not remain at a fixed distance from any closely adjacent surface and the rapid alteration of this clearance assists in turning up the leakage steam and preventing its exit.

Thirdly, my critic has plainly not understood what is meant by the expansion of steam at a continuous flow against a series of pistons having what is termed an infinite receiver between them. The term "infinite receiver" does not refer to any receiver, but to the series of spaces between gears in a single-stage engine, but to the chambers which enclose respectively the successive pairs of gears in the multistage unit. An infinite receiver is a chamber which is so large that the pressure of any gas within the temperature and pressure of steam is constant. Therefore the several stages of a multistage gear engine or multistage turbine are properly considered an infinite receiver, inasmuch as the continuous flow of high-speed steam is so close that any change of temperature or pressure is negligible.

I doubt if Mr. Ferguson has grasped the principle moreover, upon which the steam acts in this engine. The steam is admitted above or below the intersecting point of the gears according to the direction in which they are meant to be propelled, and being confined by the outer piece, forces the teeth away from the intersecting point by pressure energy, precisely as against a piston. It does not act with an impact, such as with turbine blades. The work done by this first pair of gears corresponds to the work done in a cylinder engine up to the point of cut-off, and it is by combining with one or more additional sets of gears having less of increasing area, that the expansive power is obtained. In a piston engine the internal energy of steam is utilized expansively as pressure against the piston after the point of cut-off. In a turbine, in the form of kinetic energy, the steam is used up as it expands. My multistage gear engine utilizes the pressure energy of steam while expanding it at a continuous flow.

The best experts on thermodynamics acknowledge that the use of such a cycle as mine and any advantages of it are not understood by Mr. Ferguson. I please note that Prof. Darr of Columbia was quoted thus in your article "The advantage of this cycle lies not so much in the cycle itself as in the form of the machine which the cycle is used in." Mr. Ferguson states that the very high percentage obtained (at the brake) of the theoretical work of my cycle that enables the water rate of this engine to be excellent, although the cycle itself is not claimed to be, in a limited number of cases as in the Rankine cycle. Using Darr's data, let us see the water rate obtained from the single-stage engine for one stage is 40 per cent of Rankine, two-stage 80 per cent, three-stage 77.5 per cent, four-stage 81 per cent, eight-stage 91 per cent. In an infinite number of stages my cycle equals the Rankine cycle, even though the steam does not at any time expand adiabatically. But while in the single-stage my cycle is only 40 per cent of the cycle upon which all other types of engines are based, nevertheless the water rate, when the water rate obtained from the single-stage engine is better than those of the average piston or multistage turbine of equal horsepower. It can be readily seen that a multistage gear engine which utilizes increased pressure should equal, even in small units, the economy of the largest turbines now in use. New York City. C. H. CLARK

Launching a motor boat at Dayton, Ohio, to go to the rescue of flood victims.

## The Recent Great Flood

What May be Done to Prevent Such Inundations in the Future

(Photographs by Underwood and Underwood)

**D**URING the latter part of March and the early part of April of this year the Ohio River system was visited by the most remarkable flood in its history. The successive phases of this occurrence were as follows:

(1) Torrential and long continued rains over the north-central watershed of the system, dating usually from March 23rd. At many places the rainfall was without precedent. Thus up to the morning of the 27th Bangorville, Ohio, had a total of 9.50 inches (the normal rainfall for the whole month of March at that place is 1.93 inches). Marion, Ohio, 10.00 inches (normal for the month, 3.51 inches). Bellefonte, Ohio, 11.10 inches (monthly normal, 3.79 inches). Eye-witnesses describe the rain as coming down in solid sheets, as in a cloudburst. Previous conditions were not especially favorable for floods. River stages were not high before the great rains began; there was no snow on the ground, to cause by its rapid melting the sudden swelling of the streams, as so often happens in spring freshets, and lastly the ground was not frozen—a condition that prevents the rain from soaking into the soil and thus increases the percentage of run-off. Nevertheless, the rivers of southern Ohio and Indiana experienced the worst floods on record in that section. Flood warnings were issued from Columbus by the Weather Bureau on the night of the 23th, a few hours before disastrous conditions began. No one, however, could foresee the magnitude of the deluge. While flood prediction for such rivers as the Ohio and the Mississippi is comparatively easy, with the present elaborate system of river gages and rainfall stations, and becomes more and more accurate with increasing distance from the headwaters of these rivers, no means is known to science of giving timely and accurate warning of high stages in the smaller tributary streams. The weather

Life lines strung across a Dayton street to save persons floating down on wreckage.

Woman and child rescued from their home in the flooded district of Albany.

map is an uncertain guide, for while, on the one hand, with the provisions of certain types of weather the forecaster can be certain that floods will not occur with other more or less frequent types there is always danger of floods, but the danger is not so clearly indicated as to warrant the forecaster in alarming the community with warnings that, nine times out of ten, would not be verified.

(2) By the morning of the 29th the rainfall area had spread to the southern watershed of the Ohio, and also to the headwaters above Pittsburgh. Thus from north, south and east huge volumes of water were pouring into the main river, along which flood stages were soon exceeded. The flood on the Ohio, although attended by stages exceeding at some points any ever before recorded (at Parkersburg the previous record was exceeded by 5 feet), entailed little if any loss of life, as its occurrence was foreseen in good season. A high water crest normally takes a day to travel from Pittsburgh to Wheeling, another day to reach Parkersburg, three days more to reach Cincinnati, and six days more to reach Cairo. These figures are considerably modified by the compounding of wave-crests from tributaries, but they illustrate the fact that the movement of a flood along a great river is relatively slow, and if the forecaster knows in a general way the conditions over the tributaries he can predict river-stages from day to day at down-river points with considerable accuracy.

(3) On the morning of the 27th rain or snow was still falling over the whole watershed of the Ohio and throughout the northeastern States. Serious floods occurred in several sections outside of the Ohio system. The James River, at Blain, Mead, reached 17.5 feet (7.5 feet above flood-stage) on the 26th. Floods were widespread in the State of New York. At Albany on the 19th the highest stage ever

previously recorded was exceeded by 1.2 feet, at Schenectady by 2.2 feet. On the 27th the weather cleared up all over the eastern States.

(4) At the beginning of April the center of interest shifted to the lower Ohio, where the flood proceeded normally, as there were no further rains of any consequence to complicate the situation.

From the foregoing summary it will be seen that of the four periods into which this series of floods may be divided, only the first was particularly striking and sensational. It was attended by a great loss of life, as compared with ordinary river floods in this country, although, according to present estimates, probably not more than a tenth as great as that caused by the bursting of the Johnstown dam, in 1862, or that attending the irruption of a storm-wave at Galveston in 1901 and almost insignificant compared with the loss of life in some of the river floods of China and the storm floods of India. It was, however—not to mention the colossal damage to property—great enough to arouse throughout the country public interest in the question how can such occurrences be prevented?

An enormous amount of earnest thought has been devoted to the same question in connection with earlier floods. The solution of the problem is still remote, but much has, at least, been done toward erecting erroneous ideas. Thus, it was once generally believed that floods were largely the result of deforestation. Today the relation between forests and floods tend to become a merely academic question, or, at least, no competent student of the subject now looks upon the forest as a factor of prime importance. Contemporary opinion is perhaps best reflected in the recent "Final Report of the National Waterways Commission," which is based upon the views of numerous experts in and out of the Government service. The gist of this last report, so far as it concerns forests, is that, under one set of conditions they may exercise a beneficial influence on stream flow and floods, under another their influence is probably harmful—while the fact that they have any important influence remains to be demonstrated.

The same report discusses at great length the practicability of storage reservoirs for (1) flood prevention (2) the prevention of damage to the navigation system, and (3) the production of power. One great obstacle to the success of such reservoirs is the fact that in proportion as they serve one of these three purposes they are less well adapted to serve the other two. To quote from the above-mentioned report:

"To obtain the maximum effectiveness for flood prevention, the reservoirs should be lowered as soon as possible after a heavy rain sufficiently to afford storage capacity to catch the water from the next storm. This means less power developed and less benefit to navigation. If reservoirs are operated primarily for navigation they are filled during the rainy season, and water is held until needed during the summer months. If, after they are filled, a heavy rain should come, they would not be in a position to catch and hold any of it, and, therefore, could exercise no influence upon the flood level."

Methods of avoiding this difficulty have been suggested, but they involve reservoirs of relatively large capacity and proportionate expense. However, the whole question of using reservoirs for any of the purposes mentioned hinges upon the relation of their cost to the value of the results to be obtained, and as the country develops, this question is likely to solve itself, at least in small and densely populated river basins. This is substantially the opinion of the National Waterways Commission, which has declared that "flood prevention is primarily a local problem, and the work of controlling floods should be undertaken by the minor subdivisions." The coordination and consolidation of such efforts will, no doubt, rest ultimately with the Federal Government.

#### Removing Stains From Tea Cups

To remove stains from tea cups or any other porcelain ware a paste mixture of salt and strong acetic acid should be used. The mixture should be applied with a cloth, and after the stain is bleached out the cups washed and dried.

#### Cocaineomania at Montmartre

THE Société de Médecine Mentale and the Société Médico-Psychologique have recently been investigating the new epidemic of "cocaineomania" which has broken out in the famous Parisian suburb of Montmartre. Dr. Marcel Briand, the alienist of the Sainte Anne Asylum, has made an especial study of the question, his latest assistant, Dr. Vichon, who, at his request, visited Montmartre to explore, gives in *Le Temps* an interesting account of the conditions, which are substantially as follows: It is all a matter of fashion and snobbery. Fashion has the great influence in the suburban life of Montmartre—everybody there is as concerned about the doing and the behavior of everybody else as if it were a little provincial town. They

toots or female attendants attached to the cafes and other resorts—who put the poison into small boxes and sell it as high as four or five francs per gramme. In the middle class one often sees young women seated at tables with a glass of port and one of these easily recognized little boxes in front of them. As the supply diminishes, late at night prices rise and sometimes as much as forty francs is paid for a gramme of cocaine snuff—often adulterated at that. There are mysterious ways of obtaining the drug in night, for instance, you throw a pebble at a lighted window, a little basket tied to a string is let down, you put a certain sum into the basket, it is drawn up and let down again with the worth of 300 francs for each—in cocaine. At least half the women known as

*femmes de Montmartre* are addicted to cocaine. One reason for the extent of the habit is the ease with which it is practiced—in need of pipes, as for opium or hypodermic injections, as for morphine. Moreover the desired effect is produced by the very first dose and not after one or two experiments, as is the case with morphine.

The cocaineomania is recognizable by several signs. The method of taking the drug induces a habit of sniffing. Eventually nervous of the usual cigarette smoke the victim is subject to tremors and reaches her hands for the little packets which she thinks she feels buried under the skin. In a more advanced stage hallucinations come on, she thinks she hears voices insulting her and she attempts to quarrel with which and in poison. A morbid longing for rapid movement in drives the victim to take long, automobile rides with or without means to pay the fare. The end of it all is the lunatic asylum reached by way of the police courts.

Preparing to dynamite a jam at one of the bridges in Youngstown, Ohio.

#### The Singing of Telegraph Wires

A newly discovered has been going on in the German periodical *Die Welt* as to the cause or causes of the singing or humming of telegraph wires, and the possible relation of these sounds to the weather. Much appears to be a widespread belief that the singing is a portent of storms and rain, or according to another version of cold weather. As long ago as January, 1900, the *Journal* above mentioned republished from a German newspaper an article by Dr. Egidius von Brunnick in which the writer claimed that infallible weather predictions could be made from these sounds: the pitch and loudness of the sounds indicating how soon bad weather would occur.

The recent revival of this subject dates from a suggestion made a couple of years ago by Prof. Arthur Held of Ottawa (quoted in *Die Welt* of December, 1911) that the immediate cause of the vibration in the wires was a "bend in the rest." In the ground this in turn being a harbinger of low weather.

The obvious explanation of the singing is that it is due to the wind as in the Kollan hury it is claimed that the sounds occur when the air is absolutely calm but of course there might be some movement of the air at the level of the wires when there was none at the lower level of the observer. Otto Mosbauer who has been making systematic observations of the phenomenon during the past year is unable to find any relation between the sounds and the force of the wind but he does find that the direction of the wind relative to the direction in which the wire runs is an important factor. His line of observation shows the fact that the singing of the wires is by no means simultaneous at places only a few miles apart. This fact as well as actual comparisons with seismographic records appear to dispose of the hypothesis that the singing is due to microseisms. Mosbauer has also discovered the belief that the sounds foretell bad weather.

Variations in the pitch of these sounds may reasonably be ascribed to changes in the tension of the wires with varying temperature.

A Terrible Hot Windstorm, which occurred in Tasmania January 13th did incalculable damage to the fruit crop of that colony. In some districts the crop was entirely wiped out, while elsewhere the orchards lost from 40 to 80 per cent of their fruit.

One of Dayton's principal streets as it appeared when the floods receded.

even have their little monthly papers to report the doings of the well-known local characters. These sheets inform you, for instance, that Mademoiselle Jane or Mademoiselle Irène has just been cruelly abandoned and is coming herself with cocaine, or, to use the shorter Montmartre term, with "coo".

Naturally, as the poison has been spreading for some years, a considerable illegal traffic in it has come into existence, in spite of the vigilance of the police, who are almost powerless to suppress it. The cocaine is procured by the employment of prescriptions, which are shown at one pharmacy after another, or else from druggists who sell the poison without asking any questions. These transactions are not conducted by the consumers themselves, but by go-between—

# A Narrow-gage Self-propelled Passenger Coach

A Novel Gasoline Car with Transversely-mounted Motor

By Stanley Petman, M.E.

WITH the practical perfection of Dr. Rudolph Diesel's internal-combustion locomotive which already has undergone successful trials in Germany, greater attraction is bound to center on the self-propelled passenger coach utilizing comparatively cheap oil fuel or even gasoline. For it has been demonstrated that the total operating expense of vehicles of the latter type employing the lighter hydrocarbons, can be reduced to nearly one quarter that of a steam locomotive with one car and half that of an after hauling engine coach.

Although gasoline propelled passenger coaches of standard size and size are used in a considerable extent additional interest attaches to the car of which a photograph is reproduced herewith in reason of the fact that it was constructed for special purposes which restricted the permissible gage to 7 feet 6 inches instead of the standard 4 feet 8 1/2 inch gage. It is one of five recently shipped to Australia for service on the Queensland government railways, and though its principal point of difference from others of its kind lies in its narrow gage, its construction also incorporates a number of other interesting features.

Thus, for instance the engine is placed transversely to the chassis instead of longitudinally as is the usual practice. It is a monsoir six-cylinder motor with a bore and stroke of 10 inches and 12 inches respectively. It drives all four wheels of the forward truck through the intermediary of a mill type disk clutch and a simple two-speed gear which results the necessary reduction for starting and slow running. The transmission of power between the two pairs of wheels, as may be seen by the accompanying photograph, is by Morse silent type chains, and it is understood that the mechanical efficiency of the arrangement is as high as 90 per cent. The engine is rated at 200 horse power and as it is air starting and reversing, no provision for a reversing gear is necessary. The remainder of the power unit embraces 2-foot steel tire, cast steel center drive, and is carried in 14 by 10-inch journals, the wheel base of the trucks is 6 feet and of the complete car, 40 feet.

Another point of difference between this car and others is that the position of the operating levers has been reversed for left side control. Also, instead of the standard Master Car Builders Association's coupling a side type of buffing gear with draw hook and screw couplings is employed.

The total capacity of each car is 60 passengers, of which 15 are accommodated in the main compartment and the remaining 45 in the smoker, which is next to the operator's cabby box. To facilitate the handling of passengers at elevated as well as at road side stations, the center entrance is depressed, the step comes very close to the ground. Artificial illumination is provided by a complete self-contained electric lighting system.

The weight of the car is 60,000 pounds and its

principal dimensions are as follows. Length over end-sills, 50 feet; length over buffers, 52 feet 8 1/2 inches; width over chassis, 8 feet 0 inches; length of passenger compartment, 81 feet 7 1/2 inches; length of smoking compartment, 8 feet 0 inches; inside height from floor to ceiling, 7 feet 8 1/2 inches; distance between center plates, 34 feet.

The cars were shipped to Australia completely

large amount of useful information in a systematic and classified form. This effort of the Forest Service to diffuse information on imported woods is certainly to be commended. It is surprising how little is known generally of the various imported woods, and these publications will be read with interest by many.

The circular on greenheart is not a mere compilation of facts from unauthoritative sources,

but it is a thoroughly practical work. Without pretending to be a treatise on the mechanical properties of the wood, it furnishes valuable descriptive details of the gross characteristics and special information on the microscopic features, which serve in distinguishing this wood from its inferior substitutes. The various powerful tendencies of modern building and marine construction seem to point strongly toward a larger consumption of this valuable timber. It is the duty of experts to take the initiative as regards supplying a discussion dealing with the gross and minute characters of the wood, which will be of service to the wood user in determining just whether the wood delivered to him as greenheart is the genuine kind. There are other closely allied trees whose woods are coming into general use but the test of years has shown that they are far less serviceable. A more accurate knowledge of the structural characteristics of greenheart is imperatively necessary to be able to discriminate between the true and the inferior allied kinds, the timber of which, notwithstanding the close specific affinity of the trees themselves, is often found to be widely different in its adaptability to a particular work or in its resistance to the ravages of marine borers or other destructive animals. Hence descriptive details and good sharp illustrations are now offered in this publication, which will render the recognition of this leading British Guiana timber safe and altogether free from difficulty.

## Fuller's Earth

FULLER'S earth derives its name from its use for the fulling of cloth, but this is now its principal use. Its principal use in the United States is in bleaching, clarifying or filtering crude oils and greases. In clarifying oil the earth is first finely ground and then packed into long cylinders through which the heavy, black, mineral oils are allowed to slowly percolate. The oil which first comes out is perfectly white-clear and thin. The succeeding oil becomes yellower and yellower as the earth becomes charged with impurities until after a maximum charge of impurities is reached the Fuller's earth itself is clarified by a washing process, when it is ready to use over again.

In clarifying vegetable oils a different method is employed. The oil is heated in bulging to large tanks, when Fuller's earth is added and stirred with the heavy saltwater is then poured off through bags and the clarifying matter retained until the oil is of a very pale straw color. Our present knowledge of Fuller's earth is drawn from its use in clarifying oils.

Narrow gage gasoline motor car for the Queensland Railways, Australia.

Two hundred horse-power transversely-mounted engine of the gasoline motor car

knocked down" and will be set up on arrival by an expert in the employ of the manufacturers.

## Greenheart Timber

AIRCRAFT just issued by the United States Forest Service contains a mass of practical and very useful information on greenheart. The want of such a treatise has long been felt. Indeed, there is an urgent demand for a work furnishing full information on this wood, its availability, price and properties. Much a work, appearing concurrently with the use of this wood in the lock gates at Balboa Canal Zone, will naturally be in demand and will prove of very great value to builders, engineers, contractors of marine and naval construction, and wood users in general. This circular on greenheart is the fourth of a series of publications on the commercial woods now imported into this country. In them is condensed and arranged a

## An Improved Drill Press

By W. D. Graves

FOR an occasional light job a large cabinet maker's clamp and a ratchet brace may be made to serve as a very efficient drill press. A short stout wood screw or flat-headed rivet, with the point filed to a smooth conical point, serves as an end bearing for the three spindles, while the piece to be drilled is placed against the end of the clamp screw, all as shown in the accompanying photograph.

Emergency drill press for light work.

The arrangement is somewhat awkward for one to operate alone, but if he has a helper to turn the brace while he steadies and feeds the work, it is very effective indeed.

## Chipping or Dissolving Scale from Cylinders

By George Rice

THE accompanying drawings show how scale is apt to collect in automobile cylinders and accessories, and also the tools that may be used to remove it. While some owners and repairmen of automobiles take special steps for the prevention and elimination of scale matter from the cylinders, others are very careless concerning this bothersome problem and as a result they are apt to have overheated cylinders due to the presence of the foreign matter. Of course scale accumulations are caused by the use of impure water. If hard water is all that is available water softening and purifying compositions must be employed for dissolving the scale. There are patented mixtures for this purpose. Washing soda is used by some motorists with a certain degree of success.

The accumulated matter about the peris 4 and 5 in Fig. 1 was of course sufficient in bulkiness to interfere with the pistons. In order to remove this foreign substance the cover was taken off and chipping tools employed for cutting off the bulk of the matter after which soda solutions were admitted into the cylinder to act into and soften the remaining substance. In another case one of the bolt heads inside the cylinder was choked with scale as at C in Fig. 2, and the bolt had to be broken out for removal, as the nut was too firmly fixed by the foreign substance to permit of turning off on the thread. In another instance the scale had adhered for a long time on the surface of a pipe joint as at D in Fig. 3. In one place at P a hole was crossed as a result of the foreign matter gradually entering into the metal shell of the elbow. Finally when

the shell was extremely thin and lacked sufficient power to resist the pressure from within, the metal expanded and broke, making the fracture as shown.

In the best four illustrations are shown some patterns of chipping and chipping tools of a home-made style. You can buy your chipping tools of this kind in readiness for use in any hardware store or automobile dealing establishment. But often specially forged tools are wanted. You can get the tool steel blanks and have the chisels forged as wanted and to the pattern required.

Fig. 4 is a chipping tool with a 75-degree nose and from this slant you can get six degrees for the level as may be desired for the special service to which you intend to put the chisel. A common form of effective chipping chisel for removing scale from cylinders and pipe surfaces is shown in Fig. 5. A handy cutting tool for chipping into the scale matter in crevices is shown in Fig. 6. The form in Fig. 7 is useful for the average cutting service on scale formations.

Fig. 8 shows a gathering of scale on a pipe and Fig. 9 an accumulation about one of the check valves. The blow g and 4 are the result of the foreign matter slowly but surely weakening the metal by eating into the fiber and destroying it. The thinned surface cracks at slight pressure and a hole results. The best way is to examine the joints of the mechanical fluids to be coated with scale from the water and take steps to prevent the accumulation of the substance.

## Altering a Stethoscope to Locate Motor Knocks

By William R. Ingraham M.D.

EVERY physician has a stethoscope. Nearly every layman has an automobile. The stethoscope detects an abnormal heart sound and with a slight varia-

Details of the altered stethoscope

tion this same instrument detects an abnormal motor sound just as surely.

This is how the writer did it. A new diaphragm is made from a thin piece of hard rubber (an old slide from a photographic plate holder in this case). A brass dry battery bolt cut off to about 5/8 inch and with a hole drilled in the end is placed in the center of the disk and the nut is tightened up.

In the accompanying drawing 4 is the diaphragm, B the battery bolt and C a heavy wire threaded or other wire fitted into the hole drilled in the bolt. A joined

brass cleaning rod for a 0.22 rifle is just the thing.

The device is now ready for use. Place the tubes in the ears and tap the rod lightly with the finger nail. If a spring brass wire is used, it will sound like the ringing of church bells. The ticking of a watch placed on the floor is plainly heard through the wire. A very slight knock in the motor sounds loud with the unaided ear sounds like a heavy hammer blow through

Stethoscope altered to locate motor knocks.

this instrument. A valve gear knock is easily traced to the source by trying one valve after the other. Simply place the end of the wire against the valve lifter housing.

Striking in the moving gear with a long wire in the stethoscope projecting through a crack or hole in the floor and resting on the differential housing or trans mission universal joint housing, or wherever such places indicate a knock squeak or grinding is easily traced.

## Convenient Wood Steaming

By O. Baehner

THE following device for steaming, plunking on the hulls of small boats will be found very efficient.

A box is constructed of light wood or metal of the shape shown in Fig. 1. The open end should be about 12 inches long and of breadth not greater than the narrowest part of the plank to be bent. The depth is about 4 inches and at the center of the bottom a short piece of iron pipe is secured to one end of which a hose is attached. A pair of handles can be placed on each side of the pipe to facilitate handling. The edges of the open end should be covered with cloth loosely nailed or if preferred weather strips can be nailed on the sides so as to form a tight joint when the boat is pressed up against the board. The board in the bent being in place as shown in Fig. 4 a sling is placed over the end and a stick inserted in the sling to form a tourniquet with which the end of the board may be pulled. Now by applying the steaming box as shown and attaching it to the masts of a boat to a bollie or keelie the plank is easily bent and the tourniquet tightened.

There should be no hurry in moving the box as every part of the plank should be steamed in order to obtain a true curve. A pulley fixed on a firm support can be used instead of the sling. As the plunking, on the sides of a boat tapered from the center to each end, the box as stated should not be wider than the narrowest end. In order, then, to get good results when working the wider part it will be necessary to keep moving the steaming box up and down.

FIG 1

### Power Truck Emancipates the Baggage Man

By Joseph E. Baker

A railroad station and shipping wharf, the terminals of powerful steam transportation, the handling of freight and baggage by hand labor presents a remarkable incongruity. The mountain of baggage from an arriving passenger train for example, has hitherto been trundled a few paces at a time on an ordinary hand baggage truck. At the steamship dock the cargo is slowly and laboriously loaded and unloaded by a swarm of human workers each transporting a load of scarcely his own weight.

The need of some more efficient means of handling freight on platforms and docks and in the shipping departments and shops of industrial works as well, is met in the electric platform truck, replacing the laborious hand-operated truck. This sturdy, powerful little storage battery vehicle is emancipating the baggage man, stevedore and factory laborer. Instead of pushing like a pack animal a few trunks or packages of freight the operator of the power truck stands or sits at the steering wheel guiding many times the former load to its destination with no dependence on human muscle and with great saving of time.

The several different types of electric platform truck now coming into use include three-wheel and four wheel vehicles with rubber tire wheels driven through sprocket wheel and chain or through gears. The compact storage battery constituting the motive power is slung beneath the platform of the truck, leaving the platform clear for its load and entirely flush except for the steering post at the front or rear end. One three-wheel truck with steering wheel in front, used on a new New York freight pier, weighs 2,000 pounds empty and occupies a platform space of 4 by 10 feet. It can run eighteen miles on one charge of the battery at a speed of  $4\frac{1}{2}$  miles an hour, carrying a load of 2 tons. A type of four wheel truck, somewhat larger and heavier is a double-ended, built like joining two of the three-wheel trucks back to back, that is, with the four wheels arranged at the corners of a diamond figure. The truck is built in two halves, connected by a hinge joint in the rear over the driving axle, a construction which allows either of the driving wheels to drop into a rut or ride over an obstruction without straining the vehicle when loaded. The steering gear operates both the front and rear wheels, enabling the truck to turn sharp curves. The low platform baggage truck shown herewith is one of a considerable fleet now in use at the Pennsylvania Railroad Station New York, effecting a saving of about 90 per cent as compared with hand hauling.

The usefulness of these platform trucks depends largely on their ability to maneuver in a small space as in threading their way in and out of freight cars and the sides of a machine shop. The ordinary four wheel truck, steered by turning the two front wheels, has a radius of action equal to twice the wheel base. If the truck is built to steer with both sets of wheels the radius of action is reduced to about equal the wheel base. An especially powerful truck drives and steers all four wheels, and another type, designed for working in very close quarters, drives all four wheels and steers all four with the further refinement of turning each wheel so as to be truly tangent to its track on curves and reducing the radius of action to about one half the wheel base. An advantage of this arrangement is graphically shown in the annexed diagrams showing the radii of action of the three different constructions. The arrangement shown in Fig. 2 gives remarkable mobility, enabling the truck to be turned completely around in about its own length and to approach a loading platform sideways. Narrow spaces can be entered, and it is easily possible to go into a box car, proceed to either end and back out.

Power truck carrying castings in a railway repair shop.

Fig. 1.—Two wheel drive and steer; radius of action twice the wheel base. Fig. 2.—Four wheel drive and four-wheel steer, radius of action about half the wheel base. Fig. 3.—Two wheel drive and four wheel steer, radius of action about equal to the wheel base.

grains showing the radii of action of the three different constructions. The arrangement shown in Fig. 2 gives remarkable mobility, enabling the truck to be turned completely around in about its own length and to approach a loading platform sideways. Narrow spaces can be entered, and it is easily possible to go into a box car, proceed to either end and back out.

### Gasoline Rock Drill

ILLUSTRATED herewith is a rock drill consisting of a two-cycle gasoline engine whose piston connects into the hammer of the drill. The hammer is acted on directly by the 300-pound explosive pressure, and when it strikes a blow on the shank of the drill steel it is absolutely free from all connected parts of the machine. In fact, it strikes the same blow as an air drill which has no crank-shaft. The piston is returned by energy stored in a flywheel, and is picked up for the return stroke on a cushion of air. At the same time the drill steel is automatically rotated by chain and sprocket connection with the crank-shaft operating through a worm to reduce the speed of rotation. The drill steel may be either hollow to admit water and some of the explosive pressure for the purpose of removing rock cuttings from the hole, or they may be solid, in which case they are formed with a spiral conveyor that works the cuttings out of the hole after the manner of a wooden auger. The engine is of the two-cycle single acting type, free from cams, gears, push rods, etc., and may be run at a speed of 3,000 revolutions per minute. There is no defecting plate on the piston and the inlet and exhaust ports are not oppositely disposed, so that there are no leaks between the ports as in the ordinary construction.

### Automatically Operated Railway Switch

WHEN a freight train or a passenger locomotive takes a siding to permit through trains to go by, unless there is a tower man to operate the switch, it is necessary for a brakeman to go ahead and open the switch, wait until the train takes the siding, then turn the switch so that the main track will be clear, then after the engine is by, he must go to the other end of the siding, open the switch by hand, wait until the train pulls out on the main track, close the switch behind it, and keep the train waiting until he has time to walk up to it, and mount the last car. This calls for three stops of the train. To overcome this tedious process, many suggestions have been offered. Not long ago, the automatic switch shown in the accompanying engraving was installed on a siding of the Chicago and North Western Railway. Normally, the switch is closed unless operated by the hand lever. At a short distance from the switch, there is a trip which may be operated by a roller on the locomotive to open the switch. The switch is then held open by the wheels of the locomotive and the following train. After the last car has taken the siding, the switch closes automatically. The roller which operates the trip is shown at A in our illustrations. It is mounted on the end of a plunger, which fits into a cylinder B. The engineer may force the plunger out to operative position or retract it by turning an air valve, communicating with the cylinder. The roller in passing over the trip U depresses it, throwing the switch. The switch is then held open by a guard D that runs along the track. This guard is engaged by the wheels of the train, and set in depressed position.

Fig. 1.—The plunger (A) riding on the trip (C) and opening the switch.

Fig. 2.—The switch held open by the wheels running over the guard.

## The Municipal Mind of Technically Trained Men—II

By Rudolph Mendenberg, Mayor of Philadelphia

**I**T is the intention of the SCIENTIFIC AMERICAN to publish a series of monthly articles on the professional opportunities that await the technically trained engineer, physicist, chemist, bacteriologist and technologist in modern life. Last year, it will be remembered, a series of articles was published written for the most part by well known educators connected with our leading technical institutions. They showed how facilities of technology were endeavoring to meet the requirements of great manufacturing railway and municipal corporations. This year's series, written by the heads of great corporations and cities—organizations which are capitalized in millions of dollars, which employ thousands of men, and which are economically masterful—will show how great is the need of trained technical men in the following: a title, written by the Mayor of Philadelphia, shows the need of technically trained men in carrying on the business of a great municipality.—Barron.

Municipal engineering began in Philadelphia with an official who was known as a "Regulator." His principal function seems to have been to see that the rain water running off of the city of Philadelphia was not allowed to flow into the city and did not unduly disturb his neighbors. All questions affecting water courses and the laying out of roads were left to this official. He worked practically without instruments.

After a while the demands for improvements and supervision were such as required more technical knowledge and more fine instruments were introduced and used thus the "Regulator" made his bow. From those days to the present, the business of municipal administration has been multiplying and with them increased the need of technical men. It is very interesting to list the experts of different kinds now in the employ of the city of Philadelphia. We have undoubtedly over a hundred different kinds of technically trained and educated men whose knowledge of their subject has become so fully and completely extended to be considered scientific.

Turning the last generation or two, it seems to have been one of the fallacious conceptions of democracy that we have applied it in this country that if you can get enough different people to consider and try to solve a problem, the solution will be better. It is very interesting to list the experts of different kinds now in the employ of the city of Philadelphia. We have undoubtedly over a hundred different kinds of technically trained and educated men whose knowledge of their subject has become so fully and completely extended to be considered scientific. This false idea, applied almost with the passion of religion to municipal administration by designing men, has held it for two or twenty years on a very low level of technical and administrative level. The idea was fostered by politicians who wished to keep possession of the municipal reins and purse strings for their own selfish ends. They tried to teach the electorate that if anybody who really knew anything about a municipal subject was called in to set their liberties were threatened by some mysterious scheme, that the tremendous increase in the size of our city and the rapidly growing percentage of our population that lives within metropolitan areas, the same has gotten too big for a man to handle. Given the shift and most unscrupulous of our politicians and those who are holding on tight to their political control are today calling in the experts and leaning on technically trained and educated men.

Probably the first notable example of this in the development of the New York city water supply. For over twenty years that municipality has taken the position that the water supply, first of Manhattan and later for Greater New York, was too serious a matter to be made the football of politics, and almost from the start this work has been in the hands of able men and practically free from political domination. The water supplies, however, for centuries, even in ancient Rome, have been considered poor subjects for engineering education.

The present period is remarkable in that we are beginning to look upon practically everything that is done by the municipality as an engineering or scientific problem, as we are approaching everything from a standpoint of laboratory rather than thumb rule. Take street cleaning, for instance; there is rapidly being developed a scientific literature on the

subject. More and more complicated and efficient street cleaning machines are being built. The hand phenomenon is being studied in order to make it easy to get the best results, and an enormous amount of work has been done on our data. The control of this work has been studied both here and in Europe so as to be able to make the money expended give the best possible results. This was formerly considered a matter that was beyond the province of science or technical knowledge.

After having said all this, it is fair to add that if you ask any street cleaning expert what any part of our present methods will be retained in the street cleaning scheme of a few years hence, he will surely reply "No." In other words, everything that we are doing today is so far from satisfactory that it is bound to disappear and to be supplanted by a system the details of which of which we know but little today.

Another striking instance of our present day attitude is in the matter of selection of laborers. Four years ago if any lady had suggested that high-class physicians and other technical experts should be in to cut her hair, she would have been laughed at. A laborer was supposed to be somebody who by his "labour" and he one asked why he was not a doctor the other day, he said "Philadelphia out of 400 men examined for laborers, perhaps two thirds were rejected by the doctors and others who examined them, and rejected for perfectly obvious reasons. A great many of them were suffering from hernia and other maladies which clearly showed their physical disabilities for heavy laboring. At the present time the tests that we are being asked to undergo are largely physical, but now everybody admits that there are tests before that must be developed if the city is to be a model employer. We must be able to determine what the chairman of the Civil Service Commission has aptly designated a man's "aging qualities," that is, the relative amount of joy he has in his work. The man who loves his work, no matter in what occupation, will do good work.

Street lighting is just beginning to take its place as a subject for scientific inquiry on the part of municipalities. Private corporations have been collecting an enormous amount of technical data, covering at least a part of this field, but up to within the last two or three years, cities themselves have collected no technical data that could be depended upon. In this field the demand has come about through the various city and State Public Service Commissions. These commissions have inquired into the technical aspects of the work carried on by different public service corporations, and they have forced both city and State to employ men competent in conducting such inquiries. In some private employ.

Refuse disposal represents an entirely different class of municipal problem, requiring scientific attack, in that it is based not on the use of these methods, come from Germany, and they are the development of the last few years. The refuse disposal method which obtains over the greater part of Europe is now absolutely standard. The methods which we have not begun the study of refuse disposal problem.

In the past years have had the small number of officials with little technical and

presumptive validity and consequent commercial value of a patent was pointed out. It is now over twenty years since many manufacturers, attorneys and inventors, and others directly interested in, or well informed in regard to patents, began to believe that the increasing variety and correlation of the arts and consequent difficulties of classification, together with the difference between the actual and recorded states of the several arts, had passed the point at which any practicable form of organization could assure to an issued patent the degree of presumptive validity contemplated by the law of 1880, at least until the basis of patent validity, as gradually developed in the Patent Office and recognized by the public is modified to emphasize the distinction between successive inventions in the same art and between them and the actual state of the art.

But this presumptive validity of the early American patent constituted, and it is hoped can yet again be made to constitute the chief virtue of the system, and the security which it afforded to a developing inventor has been probably the greatest single human factor in the extraordinary industrial, and of late agricultural development of the country and the consequent benefits which that development has brought, and has put us in a position to continue to bring, to the entire community.

In proportion as the presumptive validity of patents has grown more and more doubtful, patent property has become our responsibility more and more the object of speculation. Those engaged in legitimate industries are finding very few patents of which they can estimate the commercial value by any method short of appeal to the courts and in the great majority of cases are unable to say whether or not patents called to their attention have any value at all, or are, in fact, valid in any particular to the period during which the full recognition of this situation was limited to comparatively few people, speculative organizations naturally sprang up for no other purpose than to make use of the large number of doubtfully valid patents for the purpose of collecting from those engaged in the arts concerned royal tithes carefully laid at figures which the intended licensee could reasonably be expected to pay rather than embark upon expensive and tedious litigations, with doubtful outcome.

The pressure upon examiners and upon the Patent Office organization generally is almost altogether in the direction of granting rather than refusing patents on pending applications. This has naturally accentuated the tendency to issue patents of doubtful validity and trivial novelty or those so slight, if at all, in advance of 'the highest skill of the calling' as to be overtaken by the ordinary progress of the art almost immediately after issue. It has sometimes been inferred from this that it lies within the province and power of the Commissioner of Patents to relieve our difficulties by administrative reforms, such, for example as to limit the scope of patentability to inventions definitely in advance of 'the highest skill of the calling' and likely to remain so long enough after date of issue to permit the progress of the art involved to benefit enough by disclosure and experiment to render the invention to make it to the public advantage to grant in return therefor, the limited monopoly now legally provided for.

The Commissioner probably has the legal right to effect such reforms, but it is not to be expected that the Commissioner of Patents can make a radical change in such practice and establish, and effectively enforce, rules which are formidable for various reasons to a large number of persons having business with it to the office. Briefly stated, simplification of methods by positive requirement of law, both to the general patentability and the administrative procedure, is what is needed." (Quotation from page 16 "Report of the Investigation of the United States Patent Office, made for the President's Commission on

**ORBIN-BROWN SPEEDOMETER FOR MOTORCYCLES**

"The speedometer of absolute accuracy!"

Built with the precision of a high grade watch. Simple, durable mechanism insures absolute accuracy and thorough dependability. Constructed on the centrifugal principle. Therefore, as accurate during the zero of December as during the torridity of July. Impossible for indicator to "wobble." Records 100,000 miles. Tells your individual trip mileage, too.

Sold by leading motor-cycle dealers.

**AT LAST!!**

A Gasoline Gauge for automobiles that is accurate and dependable—up hill, down hill, on side hill, and on the hottest and coldest days. Shows at a glance the amount of gasoline in the tank.

**The Dependo \$7.50**  
Brass or Nickel Finish

(Some of its many advantages)

Never fails to indicate when to stop. No more fuel tank overflow. No more waste of gas. No more delay in refueling. No more delay in refueling. No more delay in refueling.

Full description for installing and with each gauge included in the 1912 and 1913 Ford, Greyhound, and other cars. Also in the 1913 Buick, and other cars.

When buying auto, ask for Dependo. It will save you a lot of money. It will save you a lot of money. It will save you a lot of money.

The Editor is always glad to receive communications illustrating articles on subjects of timely interest. If the photographs are well selected and the facts reliable, the contribution will receive special attention. Accepted articles will be paid for at regular rates.

The purpose of this journal is to record accurately, simply and interestingly the world's progress in science, technology and industrial achievement.

## Control Reservoirs and the Dayton Flood

NOTHING is more greatly needed just now in any discussion of the proper means of control of the Mississippi River and its tributaries, than a proper point of perspective and a reasonable sense of proportion. The area covered by the water shed of the Mississippi is so vast, and the localities affected by the floods are separated by such great distances, that the point of view, even of the most ardent and earnest lay student of the problem has been almost entirely too limited—too much affected by what the thinker or writer or speaker happens to see with his own eyes.

In the province of such a flood as that at Dayton, Ohio, we are apt to believe that the rainfall was absolutely unprecedented. As a matter of fact, it is probable that from time immemorial the rainstorms of the Mississippi watershed, both in the intensity and the duration of the precipitation, have been about the same as they are to-day. The Dayton flood was in no sense the act of God—rather it should be termed the price which we pay in this particular direction for our modern civilization. The floods are the result of the industry of the farmer with his ax and plow, and of the modern farmer and road builder, with the ditch and drainage and the constant effort direct or indirect, to get the water which falls from the clouds as quickly as possible into the river channels.

In other days, when the fields were covered by the recent rainfall were covered with dense forests, and denser undergrowth, it took from two to three weeks for the water to get into the rivers. To-day, thanks to the general clearing up and cultivation of the country, the water from rainstorms of the same magnitude will be in the rivers within two or three days' time. On the other hand, while the farmer has been smoothing the way for a rapid run-off of the water the dweller in the cities has been encroaching steadily upon the channels which nature has provided, and the flood is self-evident to get the flood water comfortably down to the city by piling and bulkheading areas, which properly belong to the high water channel, have been mulcted therefrom for the erection of factories, warehouses and warehouses. Highways have been thrown across the channels, frequently with massive piers and lengthy abutments, reducing the total cross-section available for the flow of the water fifty per cent below that which nature had found to be necessary at a time when the run-off of the rainstorm of the same period of time was only from one fifth to one tenth of what it is to-day.

Can the floods be prevented by reforestation? Yes—provided the farmers will revert to their fields and the Government will refrain from the flood plain of the upper Ohio to return to nature a wilderness conditions and if the citizens of Dayton and other towns subject to floods will blow up their bridge piers and approaches, and raise all artificial structures until the river is restored to its original capacity. We are not prepared to do that of course. Therefore, the only way to restrain the river under the new conditions brought about by civilization is to build levees of sufficient height to contain the flood waters and guide the water safely to the sea by the shortest and most direct route. It should be done, for the sake of the future timber supply of the country, and it should be done on all areas which are not suitable for agriculture.

Can such floods as that at Dayton be prevented by building reservoirs of such extent as to hold back the flood waters and let them into the rivers, in such volume and over such periods of time as we might

which? Yes, the thing could be done, but it would involve an equal wiping out of cultivated lands to that demanded for adequate reforestation. Let us consider a few figures. At the height of the recent flood, the amount of water to be taken care of was such that if a reservoir of the size of Lake Erie had been provided for storage, twenty-four hours of that rainstorm would have caused a rise of six inches over the whole surface. Think of that—sixteen feet falling in one day to raise Lake Erie six inches!

Furthermore, if our Lake Erie storage basin were built to cover the area concerned in the flood of last month, it might happen that the next great rainstorm, say the following year, would fall not in the upper Ohio, but in the upper Mississippi, or in the central Mississippi or elsewhere, and the reservoir of the size of Lake Erie would be merely a costly testimonial to the fact that we had not taken a proper bird's eye view of the whole situation.

Reforestation can help a little, and reservoirs can help a little, but the true solution of the problem lies in pushing to completion an adequate system of lofty strongly built and properly reeved levees throughout the districts that are subject to overflow.

## Knowledge and Morals

CIVILIZATION has brought with it evils of its own. We tend to the point of view of those who do not have a living, to appreciate art and to make enthusiastically good citizens. But in the matter of sexual enlightenment our attitude is almost wholly negative. We treat the subject as something "not quite nice to speak about" and leave the young generation to discover the truths of life at haphazard with the result that their information is gained through any but good channels. In the primitive state of society competent authorities tell us, the attention was paid to these things. We of our higher civilization, leave it to the coarser elements to enlighten the ruling generation while the "better" elements maintain a prudish silence. And thus vice is bred of ignorance.

These things are not as they should be, and many of our best raised youths, cultivating their minds to earn a living, to appreciate art and to make enthusiastically good citizens. But in the matter of sexual enlightenment our attitude is almost wholly negative. We treat the subject as something "not quite nice to speak about" and leave the young generation to discover the truths of life at haphazard with the result that their information is gained through any but good channels. In the primitive state of society competent authorities tell us, the attention was paid to these things. We of our higher civilization, leave it to the coarser elements to enlighten the ruling generation while the "better" elements maintain a prudish silence. And thus vice is bred of ignorance.

## Possibilities of the Home Laboratory

IN these days of magnificent endowment, by means of which every field of science is so handsomely developed and broadened to fruition, one is apt to discount the possibilities of the home laboratory. There may be some who are deterred from entering those Rlysian fields by the reflection that isolated contributions may be lost in the vast output of our splendidly equipped institutions. The contribution of a few instances will demonstrate that there is no occasion for any individual enthusiast to be deterred because he may not be so fortunate as to be associated with a university, an observatory, an agricultural and industry is amazing what can be done with a very modest equipment indeed. For example

When Koch in 1882, announced his discovery of the tubercle bacillus, Dr. Edward L. Trudeau was living in a small house in the Adirondack Park, where he had been (how beneficent has the result since proved to those sinned) of tuberculosis. Saranac Lake was then but a rude settlement, remote from civilization, desolate in its surroundings, forty miles from any railroad. Dr. Trudeau, a copy of a book upon the subject of tuberculosis, being without special training, he went to New York to receive a few lessons from a colleague in the common

ties of bacteriology, and how to stain the tubercle bacillus.

At Saranac Lake, then, without paraphernalia other than his microscope, without access to great libraries containing manifold material on the subject, the water often turned to ice in his house (his work stove would not generally burn all night, nor was there at that time any coal in that region) Dr. Trudeau devised a home-made thermostat which had no regulating apparatus and was heated only by a small kerosene lamp. For months he lived in the apartment heated by an oil lamp, this being the only spot at Saranac Lake where they could escape freezing at night. (The Saranac temperatures may be lower than that which Amundsen experienced at the South Pole.) Under such dreary circumstances as those that Dr. Trudeau endured the tubercle bacillus in pure culture, being the second observer in America to do this, and with these cultures he repeated all of Koch's inoculation experiments. Since then the Laboratory of the Adirondack Cottage Sanitarium has produced the most successful scheme of primary importance as to its contributions and influence.

As to Koch himself. At seventeen he persuaded his father to get him a microscope, as another youth might strive for a fowling piece or another for a motor car. "Dad," he said, "I want to be a doctor. I want to know about perfecting other technical means of investigation. Even genius cannot work effectively without tools, so Koch himself took a hand in the making of just such tools as he wanted and needed. After obtaining his degree in medicine from the University of Berlin, he utilized his spare time (what young doctor has not of this commodity aplenty) in scientific study, experimentation, research and writing, but not until he had something to write about. In those obscure years, as yet unrecalled in any world famous institution, he laid the foundation of all that noble work which earned for him the title *The Father of Preventive Medicine*.

The Abbe Mende, a simple priest, experimenting on peas in a cloister garden, evolved the most valid theory of heredity. The Rev. Dr. Mendel, the same priest, evolved the physical sciences by their discoveries in most unpretentious laboratories. The clergyman, Spallanzani, started physicians investigating digestion by making a dog swallow a perforated wooden bottle into the hollow of which he had inserted a tube. The result was to learn if this is digested in the stomach by means of a ferment or through attrition by the gastric mucus. It is good for example to have richly equipped physiological laboratories and to have carefully trained men, but the fruits come essentially from the genius which is in them. A wonderfully successful teacher of physiology got that science through even the thickest haze in his classes by the agency of his personality, half a yard of string, a blackboard and some colored chalks.

## The Scientific American in the House of Representatives

SPREADING recently on the subject of the Mississippi River problem, the Hon. Benjamin G. Munn, Representative from Mississippi, included an editorial from the *Scientific American* of February 1918. The Representative said, "I am, of course, under the leave granted to me to extend my remarks in the Record." It includes an editorial from the *Scientific American* on the subject of the problem of the Mississippi. Since the digitizing of the Panama Canal this is the most serious and the most important problem which Congress will have to deal with. All three of the political parties represented on this floor are committed by specific declarations in their several platforms to the task of preventing floods on the Mississippi River and I commend unreservedly to the careful consideration of this editorial, which states the problem and the sole method of its solution more pointedly and conclusively than I have ever seen it stated before. "Every man here will concede that the *Scientific American* is one of the most important newspapers, magazines, and well-edited journals on all technical subjects published in this country, and its conclusions on this particular problem will certainly carry weight, if not conviction, to every open mind. Few gentlemen here have read this editorial, because it is not in the files of the Mississippi Editor, and I hope, therefore, that you will read this editorial, which will cover less than two pages in the Record, and yet which covers the whole subject.

"Bacon, Aristotle, and other kindred theories are studied and their fallacies exposed, and the laws of the world, which all who are informed on this subject agree is the only feasible way to control the floods, is fully endorsed. I do hope that every member here will read this editorial, because it is the only one which we will now be called upon to consider and finally settle."

## Engineering

**Progress on the Cape Cod Canal.**—It is estimated that the 26,000,000 tons of shipping which rounds Cape Cod during the year will be so far benefited by the opening of the Cape Cod Canal that it will be perfectly willing to pay a toll for the use of the canal. The 11,000,000 tons of coal shipped annually to eastern ports will find the inner and sheltered route of advantage and probably the greater part of this, or much as is carried in barges, will avail itself of the canal.

**Decline in Relative Strength of the American Navy.**—Already the United States Navy has lost the second position in much among the navies of the world that has surpassed us, and now we are confronted with the probability of having to give place to France, whose navy under the new administration has taken on new life and is advancing by leaps and bounds. The relative positions of the two fleets in 1910 will be France, two dreadnoughts, the United States, eight, France, seven superdreadnoughts, the United States, five. In that year the total displacement of dreadnoughts and superdreadnoughts will be 370,000 tons for France and 310,000 for the United States.

**Switzerland Buys the St. Gothard Railroad.**—The acquisition of the St. Gothard railroad by the Swiss government has been advanced by the ratification by the National Council of the St. Gothard Railway Convention of 1909, by which the St. Gothard railway passes into the hands of the Swiss government. The company is paid \$42,500,000 for the railroad, and in addition the government takes over the assets of the company, which amounts to \$23,418,000. This line, one of the most famous engineering works in the world, was the first to introduce those famous loops built entirely within the body of the mountain.

**A School Watch Pure Its Scholars.**—For six years the apprentice school at the Lough Valley Coal Company's shops at Drifcon has been in successful operation. It is held for one hour twice a week during working hours, and a novel feature is that the scholars are paid at their regular rates for this time. Attendance is compulsory for all apprentices. They are instructed in the applied mathematics of mechanics freehand drawing, correspondence, and all subjects useful to them in their craft. One of the chief features is that neither read nor write, yet to-day he is considered one of the best workmen in the shop. The average attendance is short twenty, and the course is pronounced by many from nearby institutions of learning to be both efficient and complete.

**Over-taxation Limits Size of Cities.**—In a recent issue of the *Wall Street Journal*, attention is drawn to the fact that the final determining factor in the growth of cities of taxation, which history has shown to be the factor to very high and burdensome limits in the greatest and most rapidly growing cities of the world. Attention is drawn to the fact that Mommens has shown that the state-tax receipts proved that in the time of Hadrian the population of Rome was not less than 1,400,000. To-day it is less than 400,000, and our contemporary draws the conclusion that the people were taxed out of the city. London has slowed down in its rate of growth, and attention is drawn to the fact that increasing taxation, due to the very costly works of improvement now being undertaken, may ultimately act with similar effect on the city of New York.

**Sixteen-mile Tunnel Through the Rockies.**—One of the most striking developments of present-day engineering is the great expense which the railroad companies do not hesitate to incur in building tunnels of unprecedented length with a view to decreasing their grades across the mountain summits. The latest announcement in this connection is that the Canadian Pacific Railroad, which states it is going to undertake the construction shortly of a tunnel that will be by far the longest yet constructed. It is to be built below its pass through the Rocky Mountains and will be 16 miles in length and will cost \$14,000,000. This is some four miles longer than the well-known Simpson Tunnel in the Alps and the estimated time of construction is seven years.

**Signs of a Fear Days' Rainstorm.**—The Weather Bureau estimates that in the four days' rainstorm which devastated certain towns and villages in the upper watershed of the Ohio River, sufficient water fell to cover fifteen million acres of land to a depth of four feet. This represents a total of about one billion gallons of water. In the presence of such uncertainty of nature, the works of man, whether they be sustaining reservoirs or artificial basins or what not, need to be made more wisely fitted for necessity. A four-day rainfall will cover such a State as Ohio with a depth of seven inches, is a phenomenon of nature which is beyond all possibilities of control by any appliances that we know of. The only way of safeguarding life and property is by the use of proper drainage. Absolutely to prevent it would probably be the work of a magician which is utterly beyond our present humanity and resources.

## Electricity

**Wireless Telegraphy Across the Bering Sea.**—It is reported that arrangements are being made between our Government and that of Russia to maintain a wireless telegraph service across the Bering Sea. This will complete the circle of radio-telegraphic communication around the world.

**Electricity from Sawdust.**—The city of Vancouver, British Columbia, has been greatly annoyed by the smoke from sawmills and lumber mills. To overcome this nuisance, a company has been formed to supply these mills with electric power. As fuel for the generating plant, however, it is planned to use the sawdust from the lumber mills' waste logs. As the power is obtained in this way from a waste product, electricity can be furnished at greatly reduced rates, and not only is the smoke nuisance abated, but the problem of disposing of enormous piles of sawdust is also solved.

**Threading Conduits Presumptively.**—A new apparatus has been designed for threading conduits. It has the advantage of being able to pass around several bends which would be difficult if not impossible with the ordinary fish-tail method. A "traveler" is provided which consists of a series of washers loosely fitting the interior of the conduit. This traveler is connected to a string or cord which passes through a tube into a compressed-air tank where it is coiled up on a reel. In service, the tank of compressed air is at a pressure of 100 pounds, and by means of a hand pump, the traveler is inserted in the conduit, the end of which is sealed by a plug on the end of the tube, and a valve is opened, permitting the air to blow into the conduit and blow the traveler through, drawing the string with it. This string is then used to draw wire which, in turn, may be used for hauling a heavy cable through the conduit.

**Sterilizing Milk with Ultra-violet rays.** The Bureau of Animal Industry has been carrying on a number of experiments with ultra-violet rays for the sterilization of milk. The milk is spread out in a thin layer by means of a drum revolving at high speed, which picks up the milk from one trough and spreads it into the conduit and blow the traveler through, drawing the string with it. This string is then used to draw wire which, in turn, may be used for hauling a heavy cable through the conduit.

**Electrolysis and Concrete Reinforcing.**—The effect of electrolysis on the iron reinforcing rods of concrete was demonstrated at the recent Cement Show in Chicago by an exhibit of the National Bureau of Standards. It was shown that low currents are set up in the iron due to moisture and impurities producing iron oxide, which, as it occupies a much larger volume than the iron, exerts a pressure that eventually results in cracking the concrete. To determine the amount of the pressure, a steel cylinder with a bore of 1.6-inch internal diameter was fitted with a steel rod of one-inch diameter and the space between was filled with cement. This was then immersed in water and the iron core was connected to an electric circuit. By measuring the expansion of the outer cylinder it was found that the oxidation of the iron core produced a maximum pressure of 4,700 pounds per square inch. A column of concrete, one foot long and six inches in diameter, and provided with an iron core immersed in water and subjected to fifty volts of current from the iron core as the anode. In three hours time the specimen was cracked. A bulletin on these experiments is being prepared by the Bureau of Standards.

**Self-Lighting Kincoscope.**—By the use of a small dynamo mounted along with the crank mechanism of a motor picture machine, the Pathé film of Paris is now able to produce a machine which is self-contained and furnishes its own current for the lamp. This makes an independent apparatus which can be set up anywhere and is very ready for use. When a current supply is not at hand, this will be very convenient. The idea is being applied in a simplified apparatus of recent design, and it is intended to be used extensively in homes or schools, as the picture machine is now known to have an educational value in the field of recreation. One point which seems complicated is the use of an over-volted metallic filament lamp, and by increasing the current much above the standard the lamp gives out a bright light for short periods of time. The lamp is very bright for three or four minutes and then goes out. A small lamp will burn for 5 or 10 hours and can be replaced very cheaply. Thus the usual lamp, which amateurs may find more difficult to work, is not needed here. The new machine also has a self-luminous film of prepared celluloid, of somewhat smaller size than the standard. In this way the machine is well within the reach of amateurs, as now there is scarcely anything to be attended to.

## Science

**The Terecentenary of Logarithms.**—The Royal Society of Edinburgh is planning to hold an international mathematical congress in June, 1915, on the occasion of the terecentenary of the publication of John Napier's *Mirrour Logarithmorum Canonicus Deputatus*. The entertainment will include a garden party at Merchiston, of which Napier was lord.

**The Search for the Minor Planets, or Asteroids,** among the number of known bodies of this class began in 1801 by leaps and bounds, with the introduction of photographic methods of search, have furnished astronomers with the opportunity of commencing all sorts of persons and things that have been observed. One of them No. 594 has just been named *Mirreale* after the heroine of a celebrated Provincial poem by *Prédéric Mistral*. This name was proposed by *Camille Flammarion* (of course) and has been accepted by Dr. Max Wolf who discovered the planet in question in 1909.

**Meteorological Work of the "Scottia."**—In connection with the forthcoming re-occupation of the North Atlantic which is being organized by the British Board of Trade and several steamship companies, it is announced that the vessel to be used for the purpose, the "Scottia" will carry a trained meteorologist, and that upper-air observations will be made by means of kites and kite-meteorographs which have been supplied by the Meteorological director of the Lindenberg Observatory. It is also announced that the wireless equipment of the vessel has been furnished free by the Marconi Company. Two wireless operators will be carried. The vessel will be stationed off the coast of the Azores, to the north of the usual shipping routes, to watch the breaking-up of the ice and report on its movement toward the shipping routes.

**"German-South American Institute"** has been founded, with headquarters at the Technical High School in Aix-la-Chapelle, for the purpose of furthering both intellectual and commercial relations between Germany and Latin America. The ambitious programme of the institution includes the utilization of its future especially periodical publications, the publication of directories and handbooks for the countries concerned, the preparation of German, Spanish and Portuguese dictionaries, and the publication of a series of monographs and so on. The Institute will be divided into a large number of sections according to countries and subjects, and each member will affiliate with one or more of these. Further information regarding the Institute may be obtained by addressing the "Gieseler-Institut der Laube-Badermann-Kunsten-Institut, Kgl. Techn. Hochschule, Aix-la-Chapelle, Germany.

**The Highest Mountain Climbed.**—The account of the Duke of the Abruzzi's expedition to the Karakoram and Western Himalayas has just appeared in the *Geographical Journal*, and the Duke undertakes this expedition chiefly to contribute to the world problem as to how high it is possible for human beings to climb. He and his guides, after living for 37 days at or above 10,000 feet, spent another 17 above 18,000 feet, of which 9 were spent at or above 21,000 feet. In an ascent on Bride Peak, the party camped at 22,483 feet and the next morning climbed to 24,000 feet. Thus having the man-level 700 feet higher than any previous mountain ascent. Only a heavy mist prevented them from reaching the summit (25,110 feet). The most remarkable part of the story is that the Duke and his party were able to climb, and were little the worse in any way for their exertions. Aposoph of this fact an interesting series of letters on the subject of mountain sickness, from correspondence with the Duke, and a number of papers appearing for some months in the *Geographical Journal*. There are few subjects on which opinions differ more widely.

**Primitive Art.**—The numerous discoveries in the way of mural paintings and drawings of paleolithic caverns which have been made in Europe and Asia are well known and illustrated in the recent publications made under the auspices of the Prince of Monaco and the two volumes relate to pictorial art of the epoch known as Magdalenian. The first volume, which is the first of a series, in 1872, were followed by many others and these confirmed the existence of a quaternary art of remarkable value. Systematic researches in a great number of caverns showed that this art was spread over other regions, for instance in France, where M. Ravert published the drawings from the La Motte-Berard in the Dordogne region. Handmade and large-sized polychrome frescoes then came to light in the Combarelles and other caverns which have been made in the same field. The study of the subject was taken up and the publication devoted over owing to the Prince of Monaco's liberality. Messrs. Captain, Beaulieu and others who were active workers, now determine the form and position of the caverns, the date of the discovery of the paintings, and draw a parallel between the animal forms and those of existing animals or of animal remains which we possess.

## English Multicycles for the Blind

By Frank C. Perkins

THE first multicycle used by the pupils of the Royal Normal College for the Blind was a *Reo* Sociable cycle, which Mr. Francis Campbell obtained. When the double Sociable was developed two of these machines were obtained in 1884 and with two slightly improved to steer the blind pupils often went on short trips. Mr. Francis soon exchanged this Sociable for a tandem and had two other tandems joined for a four in hand.

As it was important to have a machine on which one sighted person could steer for more than three blind riders, the multicycle manufacturers were asked to construct a machine to carry eight, and a number of experiments in compliance were tried. Mr. Francis with his son and a practical number of the staff of the college for the Blind made several visits to Coventry to test the experimental machines. Finally a satisfactory one was built in 1888 and given to this college for the Blind through the help of Mrs. W. W. Astor, Mr. John Cook and the principal.

The institution was soon provided with an addition of two six in hands, a four and a three, so that a party of twenty-seven blind people could be taken out for an afternoon run. The *Minger* military multicycle was then developed and a twelve in hand was built for the Royal Normal College for the Blind in 1908, and that machine is still in use. It has six pairs of wheels with two riders for one axle and the six pairs are connected by swing and knuckle joints.

The latest multicycle seen in the photograph is very sensitive to the steering done by the second rider and it will turn in its own length and can be divided into two sixes or three fours. Its length is 28 feet and it is geared to 51. With this multicycle runs have been made to Derby, Birmingham, Brighton and other towns. Until the motor traffic monopolized the roads, the machine was in constant use by the blind boys and girls and there was no outing they enjoyed more than a run on the Brighton road. There is a track of three laps to the mile in the grounds of this asylum for the blind, where the pupils practice.

For recreation at the Royal Normal College and Academy of Music for the Blind at Upper Norwood, London, England, a number of these college multicycles are used as shown in the accompanying photographs. A team from this institution for the blind rode from London to Brighton and back, a distance of 100 miles in 10 hours 45 minutes running time. The riders for this trip were chosen from 90 candidates. The length of the machine is 28 feet and the gear is 51. The second person steers this machine and the others simply propel the combination vehicle.

### A Chapel on a Motor Truck

CHAPELS on wagons, on railroad coaches, on boats—we have heard of all of these, but a motor chapel—this is something new. Motor chapel St. Peter, it is called and it was presented to the Catholic Church Extension Society by a member of a western branch

of the Women's Auxiliary. It will be used to penetrate sparsely settled regions that are beyond the reach of the railroad. Starting from Brownsville, Texas, the chapel in charge of two priests, will tour the Rio Grande River westward through the State.

Mounted on a standard two-ton motor truck chassis,

Two "Sociables" connected in tandem

A party of blind students off for a trip on a twelve-seated multicycle.

is all the necessary religious equipment. When the car is on roads its number gray finish, the eight cathedral windows with a cross design in the center of each, and the coat of arms of the society will distinguish it from commercial vehicles and give to it an appearance of individuality. When the car stops at a place for service, the rear door and hinged panels at the side open out and a drop platform is spread down giving approximately double the floor space thus forming a sanctuary of ample size. In the center of the platform extension is set a quartered oak combination altar and vestment cabinet with its ornamental brass accessories. Along the outer edge of the platform brass standards are fitted and provided with heavy ball cord guards. The floor of the platform is covered with a deep green Brussels carpet, and a green draped curtain hangs from the platform to the ground. To the right of the altar in one of the photographs may be seen a small folding organ, while in the foreground is a rack fitted with large tubular bells for outside use and a small chime for use at the altar. The equipment also includes a stereopticon, the power for the lantern being

supplied by an electric lighting system, with which the car is completely provided. As a shelter from rain or the heat of the sun, a 20 by 50-foot cable roof tent with 74 foot walls is furnished. When not in use, this is folded up and carried on the roof of the car.

Living quarters for two priests are provided in the forward end of the car. When the altar is not in use it is pushed to the extreme rear of the car, giving plenty of room for living quarters. In this forward space are contained lockers for personal effects, lockers for folding coats, bedclothes, drawers for books, stationery, a typewriter, cooking utensils, tableware, and a light supply of provisions. As many as three cots can be erected in berth style, suspended by means of brass chains, so that the priests and a chauffeur may be accommodated. In addition to this there are two extra arm folding cots for use, when desired, outside of the car.

### The Good Roads Movement

THAT there are upward of \$400,000,000

of good roads bonds issued and outstanding is indicated by the *Good Roads Year Book of the United States*, the 1911 edition of which has just been issued, containing a résumé of the whole road situation. It is evident that whatever may be the faults in methods of construction and maintenance, money is being spent in sufficient amount to bring about a vast improvement in the public roads. The Year Book shows \$137,000,000 of State and road bonds authorized, and \$100,000,000 of county bonds outstanding on January 1st, 1911, making a total of \$237,000,000. As this is based on reports from about 70 per cent of the counties in the United States, and as a large number of the individual townships have not reported, it is estimated that the amounts not reported would run the aggregate up to probably \$350,000,000 to which should be added ten or fifteen million dollars of the bonds voted in 1912 which have not yet been issued.

Encouraging progress in road construction during the past few years is indicated by the statement in the Year Book that while the percentage of all road improvement in the United States at the close of 1900 was 8.00 per cent, the revised statistics to December 31st, 1911, show an improved mileage of 10.1 per cent, or a net gain of 1.44 per cent. This does not sound so impressive in terms of percentage but it means that in the two-year period more than 34,000 miles of improved roads were constructed or 10,000 miles more than the entire mileage of national roads in France.

### The Ghent Food Congress

AT the Ghent International exposition which opens in April there will be held a congress of food adulteration and fake subjects. An interesting feature is a section where will be exhibited natural products in raw and purified state along with imitations or different kinds of adulterations. Model laboratories where food products are manipulated will also be seen by the public. Numerous lectures illustrated with lantern or moving picture projections, form another attractive feature.

The chapel opens and ready for service.

Motor chapel St. Peter as it appears on the road.

### Premature Explosion of Shells in Three-inch Field Guns

**P**ICTURED herewith is a three-inch gun of the field artillery of the United States Army, which exploded when being fired during target practice near Fort Canby, Pa., on last October 4th. This gun was made of high carbon steel, of which material most of the field guns of our service are made, and was of the built up high power variety, the principal parts of which consisted of a tube, jacket, locking hoop and clip.

These guns have a total length of 57 1/2 inches and weigh about 900 pounds. They fire a 15-pound shell and have a muzzle velocity of 1,700 feet per second, a maximum range of 6,800 yards, or about three and seven tenths miles, and are designed to stand a maximum pressure of 35,000 pounds to the square inch.

Fortunately none of the officers or men attached to the battery was killed by the bursting of this gun and none seriously hurt, which is but another of the mysteries often accompanying the exploding of ordnance, for the gunner whose seat is on the left of the breech and directly under the rupture had just left his seat and was sustained only slight injury from flying splinters. No 1 man of the gun crew whose seat is on the right of the breech was in that position and escaped unhurt.

At the time of the explosion the gun was loaded with a high explosive shell containing what is known as "F" powder and was loaded by the usual charge of approximately 24 ounces of nitrocellulose powder.

When the gun was fired the breech block was blown 90 feet to the rear (here by misdoing a soldier who was holding a horse) and the whole of the rear body of the gun was blown open on the left side, under a distance of about three feet. When examined after the explosion the forward or lead end of the shell was found to be in the bore of the gun, near the muzzle and a piece of the base was jammed at a decided angle in the bore about 50 inches from the breech.

Another more serious explosion is also illustrated herewith. It took place during the practice of the 8th Cavalry Militia two years ago, and it resulted in the death of the gunner.

It is hard to decide definitely the cause of these explosions, several of which have occurred in the firing of 3-inch field guns, and with varying results. One thing however is clearly defined: whether such explosions are accompanied by loss of life or not—expensive and valuable property, a character of which we possess far too little is totally destroyed. The most recent models of these guns are built of nickel steel, and to test their ability to stand the shock of premature shell explosion they have been subjected to a practical test, by the exploding of a shell in the gun chamber and with the gratifying result that the gun built of nickel steel is capable of standing the great strain without rupture. Our field artillery is inadequate, and our nickel steel guns too few.

### Dogs for the Dutch Army

By W. J. L. Kiehl

**D**URING the military maneuvers last summer it often happened that the *mitrailleur*—a quick firing machine gun for the infantry—arrived too late at the point of destination.

This inefficiency was caused by the difficulty of transport, for the gun with support weighs 175 pounds, the gun being 40 pounds and the support 135 pounds. This is a heavy load for men to carry, combined or separate. To remedy the difficulty the Dutch army authorities are now making experiments with the invention of a Belgian officer, i. e., a very light cart drawn by two strong dogs. This device has already been adopted by the Belgian army for the transport of infantry *edward* *lewis* and has been found extremely satisfactory—even more so than the transport by horses of this same kind of guns for the artillery.

The very light cart, whose construction can be plainly seen in the photograph, weighs 350 pounds. Dogs and cart can

very easily jump across any obstacle in the way and the gun can be placed in position by two men. The same kind of carts and dogs are used to transport the ammunition.

The way the dogs are harnessed is plainly shown in the picture. So proud are the dogs of their task and so faithful that none other than the men of the com-

pany is allowed to touch them. However, was too frail to be adapted for ordinary use as a fuel. At the same time it was observed that an important role was played by small amounts of oxygen in the gases surrounding the heated mass of coal.

More recently this line of investigation has been followed out further by Prof. S. W. Parr in collaboration with H. L. Olin. They find that under suitable conditions it appears to be feasible to prepare from Illinois coals, by cooking at low temperatures a coke satisfying all ordinary requirements as regards texture and fracture. We say "under suitable conditions"—for it appears to be essential to maintain an oxygen-free atmosphere around the coal during the process. This was accomplished in the experiments of Parr and Olin by heating by means of steam introduced directly into the retort. At the temperatures employed there was no chemical action between the coal and the steam.

The authors conclude from their observations that the fusible substance of Illinois coals is the true binding material in the coking process, that it is present in such abundance as to produce a coke of too open and spongy a character as a result of the evolution of the large amount of gaseous products which result from the decomposition in this respect is paralleled by the behavior of sugar in the process of coking, which yields as a result of the large volume of escaping gases a very porous mass of sugar coke or carbon. However, if the raw coal is mixed with a considerable amount of material which has already gone through the coking process, or which has at least given off the larger part of its gases, and this has been reduced in a fine division like bread, the resulting material of the fresh coal is able to disintegrate through out the mass and the gases may also escape without any serious expansion of the mass, with the result that a coke of good texture is formed. Exactly in a similar way if molasses or other sugar or glucose material be substituted for the fresh coal we shall have again the formation of a dense coke capable of retaining its shape under conditions of firing much better than when a plastic binder is used. In both cases a strongly caking mass is produced, which meets the requirements of handling, storage and combustion with the greatest efficiency and the least formation of smoke. A small admixture of raw coal may thus be made to serve the purpose of a binder for material otherwise wasted as coke breeze at a cost which would enable it to compete with the pitch binders now in use. This suggests a process of fractional coking or coking in two stages. The first result at the lower temperature furnishes a product which, when ground to a moderate degree of fineness and mixed with the small portion of fresh raw coal, would furnish the essential conditions for producing a coke of dense nature, with a binder so distributed as to give the material a strength quite comparable with that produced by coals of the regular coking variety. Moreover an advantage would be evident in such material especially for use in house hold appliances in that it would be more likely to burn in a complete and less difficult of manipulation in the matter of maintaining a fire than coke made by the usual methods.

For further information regarding this important investigation the reader must be referred to our current SUPPLEMENT. We shall here only add a brief reference to the work of another investigator, Dr. E. B. Douglas, who has shown that by working under pressure and at a moderate temperature we can accomplish in the brief space of a few hours a result closely analogous to that produced by nature in a long time. He heated cellulose at 150 degrees in water in a closed electrically heated furnace until the pressure became 800 atmospheres. Samples were taken from time to time and it was found that the cellulose had been changed to peat. The result was obtained in twenty-four hours, no further change being obtained in sixty hours.

By applying the Van't Hoff second law of reaction velocity, it is found that the same change from cellulose to peat at 150 deg. Cent. requires 7,000,000 years—a geological period.

An explosion that resulted fatally

pany to which they belong will dare to touch the gun.

### The Coking of Coal at Low Temperatures

**I**N a series of experiments carried out several years ago by Parr and Francis at the University of Illinois it was found that by coking coal at a comparatively low temperature say 700 deg. Fahr. or less, the heavy hydrocarbons—those chiefly responsible for its formation of smoke—could be removed, yielding a gas of high illuminating power and a tar with a high percentage of volatile oil. The solid residue in the still

possess a binder for material otherwise wasted as coke breeze at a cost which would enable it to compete with the pitch binders now in use. This suggests a process of fractional coking or coking in two stages. The first result at the lower temperature furnishes a product which, when ground to a moderate degree of fineness and mixed with the small portion of fresh raw coal, would furnish the essential conditions for producing a coke of dense nature, with a binder so distributed as to give the material a strength quite comparable with that produced by coals of the regular coking variety. Moreover an advantage would be evident in such material especially for use in house hold appliances in that it would be more likely to burn in a complete and less difficult of manipulation in the matter of maintaining a fire than coke made by the usual methods.

For further information regarding this important investigation the reader must be referred to our current SUPPLEMENT.

We shall here only add a brief reference to the work of another investigator, Dr. E. B. Douglas, who has shown that by working under pressure and at a moderate temperature we can accomplish in the brief space of a few hours a result closely analogous to that produced by nature in a long time. He heated cellulose at 150 degrees in water in a closed electrically heated furnace until the pressure became 800 atmospheres. ## Discovery of the Infantile Paralysis Germ

By Giovanni Grandpré

THOUGH at present we are unable to stop the ravages of infantile paralysis, the recent discovery of the germ responsible for it is a long step in that direction.

In no more than three quarters of a century since Hideo, a German physician, made clinical observations of a character which established acute poliomyelitis (infantile paralysis) as a disease of a distinct character. Twenty-nine years ago Strümpell first broached the theory that this, in common with certain other paralytic affections, is due to the presence of a germ.

From the time of the recognition of infantile paralysis as such, about fifty epidemics have been brought to the attention of physicians for systematic study. The one which prevailed in Poesden in 1888, and which furnished valuable data for extended research, seemed the starting point for an annual recurrence. By turns in France, Italy, Germany and the United States, human beings—principally very young children, have gone down in numbers before its blight. And in 1905, Wickham laid emphasis upon what has proved to be a most important fact, that those cases of infantile paralysis which never fully develop in certain people, pass a large part in the period of the disease.

In order to understand this, differences in the nature of residence in individuals must be taken into account. Thus a child of three years is taken sick with headache and fever. Three days later, entirely without warning, paralysis creeps up the legs, ascends to the arms and after an interval of possibly five days, later fever with the heart action and causes death.

Another child in close association with the fatal case may have precisely the same symptoms, but the fever develops rapidly, the paralysis is slight, and the abortive type which is not the less to be reckoned with when public danger from the disease is considered.

Obstacles in diagnosing the illness were for a time insurmountable, not only because paralysis came on after a preliminary illness so slight as to be overlooked, but because the patient apparently recovered, he became, sometimes within a few days, suddenly and hopelessly crippled.

The presence of infantile paralysis came to be recognized at autopsy by scars along the spinal tract not to be found in other parts of the body. Though functional changes in organs were effected, the nervous system of the trouble was manifested as a further of symptoms. When paralysis was coming on the limbs of one side of the body would be a drag on those of the opposite side, the weight resulting in fatigue.

Though adults suffered from the disease, the largest known proportion was about one fifth of those stricken in the course of an epidemic, the favorite victims being children in their third year. In country districts, the disease seemed to radiate from the public school. The carrying agent was believed to be the human being, no animal suffering from a form of paralysis that could be studied as co-related to it.

Nine years ago, Landsteiner of Vienna confirmed Strümpell's theory of an infectious agent by transmit the disease to monkeys. This made it possible to study the disease objectively by a new method and since that time scientists have been giving it great attention.

Though the infantile paralysis virus does not flourish with equal facility in all individuals, it is hard to kill its presence in the brain, spinal cord and tonsils of recently dead human beings and monkeys has been shown by inoculation, for example of material obtained from the nasal passages of monkeys. Moreover, experiments show that the germ does not die of prolonged heating or freezing unless excessive.

Much of the important work along these lines has been done at the Rockefeller Institute under the direction of Dr. Flexner. Experiments on animals afforded the belief that the infection may be carried from and to the mucous membrane of the nose by nasal speak ing coughing, sneezing, etc.

It is now supposed that the virus enters the body through the nasal passages and is carried by the lymphatics along the route of the olfactory nerve to the membranes that envelop the brain and spinal cord. Whether intermediate agents, such as flies and other domestic insects, play a part in the transmission, is not yet definitely established.

Flexner's work for a long time dealt with prevention and alleviation. During the summer of 1911 a large number of patients suffering from this disease were admitted to the Rockefeller Hospital, while a still greater number were treated in the clinic.

Meanwhile, work was going on in the bacteriological department of the Institute which was destined to have great bearing on this particular study.

A year ago, Hideo Noguchi, the Japanese scientist

at the Rockefeller, succeeded in proving for the first time the *sprochke pallida* (the germ of syphilis). This was first discovered by Schaudinn in Germany, and later developed in animals at the Pasteur Institute in Paris by Drs. Laverdier and Bourdieu.

Noguchi's success in developing it was due to very special research on which he had been engaged for some time with reference to the culture of anorectic germs, germs that cannot be grown in the ordinary manner. As Dr. Flexner suggested, not long since, that he apply these brilliant new methods to the problem of growing the hitherto undiscovered germ of infantile paralysis.

This germ appeared to be one of the so-called "ultra-microscopic" variety, that is to say, a virus so minute as to be invisible through the magnifying-glass and to pass through the pores of porcelain (Berkefeld) filters.

Acting on Dr. Flexner's suggestion, and enforcing the very strict conditions of asepsis, Dr. Noguchi has grown the germ of this frightful miasma from the brains and spinal cords of children who have died of it, grown them in human serum kept in long, deep tubes. On the top of the serum is a layer of paraffine to keep out the air, and the germs grow only in the very bottom of the tube in the position most distant from the air.

In the light of this scientific feat, these germs appear to be truly ultra-microscopic, in spite of the fact that they are small enough to pass through the Berkefeld filters. They can be seen through the microscope as exceedingly tiny granules or globular bodies, in a variety of arrangements, growing singly doubly, in short chains or in masses. They can be stained a red color, while with well known dyes they stain by means of which the syphilis germ was first identified.

As a guarantee of the genuineness of this discovery, the crucial test proposed by Koch of Germany has already been successfully applied. This test has been explained in order to establish whether the newly discovered germ is really the cause of the disease under investigation. Germs which have been cultivated through several generations have given the experimental disease in infantile paralysis to monkeys. Then they have been recovered again from the bodies of these animals, precisely as in cases which have been so constantly under observation in the past.

It is needless to say that this discovery is of the very greatest importance in the diagnosis and treatment of cases, and that it justifies the expectation that the day is not far distant when science shall have this devastating disease under relatively perfect control.

## Lightning Calculations

Extracting Roots of Numbers by Inspection

By Alfred L. Leka

AT a recent meeting of the Société Française de Philosophie, M. Quinon astonished the members present by extracting cube roots and fifth roots of given numbers at sight. The matter has received considerable discussion in the daily newspapers, but for some reason the method employed has not attracted very general publicity nor has the *raisonne* of the process been exposed. I shall first of all describe the method as reported in *Le Matin* and *La Nature*, and shall then show how the rules given follow from simple mathematical considerations.

It should be remarked at the outset that the method, as described in the sources quoted, applies only to perfect cubes, and, generally, to odd powers of whole numbers. A few examples will best serve to explain it.

As an example, let us extract the fifth root of 3,125. If, given the fifth power of any of the numbers 1 to 9, and asked to extract the fifth root, we can do so instantly by inspection of the last digit. If the number given exceeds 9 the process is a little more complicated. It becomes necessary to determine the fifth power of the first three digits, as given above. An example will illustrate the method. It is required to find the fifth root of 229,845,007; this number being the fifth power of a whole number. The last digit of the root sought is 7. To find the other digits, we must first extract the digits of 229,845,007 which precede the tens of three units and do not exceed ten billions (ten thousand millions). In the present case they are 2,298. Now 2,298 falls between 4<sup>5</sup> and 5<sup>5</sup>, as will be seen by referring to the fifth powers above. Thus the first digit, but not one of the number sought is 4, and the entire number is 47, as the reader may convince himself by trial.

For cube roots the method is slightly different. M. Quinon observes that the cubes of 1, 4, 8, 6, 9 and in 1, 4, 8, 6, 9 are the cubes of 8, 4, 6, 8, 4, 6, 9, 2, 1, 4, 8, in numbers found by subtracting 3, 4, 5, 6 from 10. The cube roots of numbers less than 1,000 are therefore obtained by inspection of the last figure as follows:  $\sqrt[3]{10-9}=9-3=6$ ,  $\sqrt[3]{10-7}=9-7=2$ ,  $\sqrt[3]{10-4}=9-4=5$ ,  $\sqrt[3]{10-1}=9-1=8$ . For cube roots of the higher numbers we must annex the cubes of 10, for  $(10-2)^3=8$  and 8 less the remainder of 4, and the remainder has a root lying between 9 and 10. The digit in the tens is therefore 9, and the number sought is 98, as stated.

M. Quinon has similar rules for extracting the 7th, 9th, 11th roots, etc.

Now let us see how we can account for these remarkable facts.

Let us consider the case of the fifth root. We want to show that the last digit of  $a^5$  is  $a$ . This is the same thing as saying that the last digit of  $(a^5-a)$  is zero, or that  $(a^5-a)$  is divisible by 10. Now  $(a^5-a) = a(a^4-1) = a(a-1)(a^3+1)$ .

It is immediately obvious that if  $a$  itself is divisible by 10, then  $(a^5-a)$ , since it contains the factor  $a$ , will also be divisible by 10. Furthermore, if the last digit of  $a$  is 1, then  $(a-1)$  is divisible by 10. But  $(a-1)$  is a factor of  $(a^3+1)$ , which is therefore also divisible by 10. Similarly if the last digit of  $a$  is 9, then  $(a+1)$  ends in zero, and so does therefore  $(a^3+1)$ .

Now if  $a$  ends in 2, then  $a^2$  ends in 4, and  $(a+1)$  in 3. Hence  $(a^3+1)$  contains the factors 2 and 3, i. e., its last digit is again 0. Again, if  $a$  ends in 3,  $a^2$  ends in 9, and  $(a+1)$  in 4. Thus  $(a^3+1)$  ends in 0. If  $a$  ends in 4,  $(a+1)$  ends in 5 and  $(a^3+1)$  contains the factor 5, and 4, that is, its last digit ends in 0. If  $a$  ends in 5,  $(a+1)$  is an even number, and hence  $(a^3+1)$  contains the factor 10. If  $a$  ends in 6,  $(a-1)$  ends in 5. If  $a$  ends in 7,  $(a+1)$  ends in 8. If  $a$  ends in 8,  $(a^3+1)$  ends in 9, and  $(a^3+1)$  contains the factors 2 and 5. Our proposition is therefore proved.

The rationale of the rule for numbers greater than 9 is so obvious as to require no explanation. The rules for the third, seventh and other powers can be explained by a similar process, which may leave to the reader to work out. I will only add that  $(a^5-a)$  is divisible not only by 10, but also by 3, as the reader may show either by inspection of the fifth powers cited above or by a process of reasoning similar to that developed here.

## The Current Supplement

MR. FRASER'S article on the construction of a self starting induction motor is concluded in this week's issue of the *SUPPLEMENT*.—Mr. R. H. Rogers writes of "our freight trucks carrying us five times as much as our automobiles," and also of "the automobile." The musician among our readers will be interested in the illustrated description of a typewriter which prints music characters.—V. Jefferson Watts contributes an article on Knowledge and Morals, which is referred to more at length on our editorial page. V. Huntington gives a simple formula for computing gyroscopic forces in aeroplanes.—A highly efficient photo-mechanical process for preparing illustrations, which has been extensively applied and promises still further development in the future is described.—Prof. J. J. Thomson continues his discourse on "The Structure of the Atom."—A Whitehead discusses some indirect causes of imperfect interchangeability of machine parts.—Prof. A. W. Wray of the University of Illinois, collaborating with H. I. Olin, has conducted important researches on the cooling of coal at low temperatures. A detailed extract of their report appears in this issue of the *SUPPLEMENT*.—R. F. Baughford discusses the effects of the temperature of the soil on the prevalence of parasitic worms in the body of the animal afflicted.

## A New Method for Cooling Mines

AN AIRMAN engineer, M. Dietz, proposes a method for cooling the mines in which water overcomes the increasing difficulties. The temperature in mines, which increases with the depth of working, makes it necessary to fix a maximum number of hours per day for the miners, and in the German mines where the temperature often exceeds 56° C. (133° F.) the men do not work more than 6 hours per turn. Such conditions cause a greater expense for labor and a lessening of the yield, and the present method is intended to keep the temperature below 30 degrees at the working points so as to allow of a continuous work in the mines in other countries. After showing the reasons why previous attempts in this direction were not successful, he explains his method, which is to compress air at the surface of the ground and then pass it through a drying process. The compressed air then goes into an expansion apparatus or air turbine, where it expands and furnishes work to its machine. The air also becomes cold by the effect of the expansion on the well-known principle, and it is then taken by means of a proposed piping into the mine and delivered at the new point so as to secure a good ventilation and a cooling of the air within the mine. In this way, he claims that this mine can be cooled more effectively than hitherto.

### Inventors and Their Needs

To the Editor of the SCIENTIFIC AMERICAN

You render invaluable aid to the inventor by publishing the letter of Mr. Kennedy in your issue of March 20th. The subject surely demands serious action. The inventor, as a rule, is not "money-wise," his vocation is to serve humanity, and he should not be deprived of reasonable compensation permitted to fall into the trap of the mercenary. Many lose through indiscreet confidence in the personal representative of capital. I happen to know through experience. There may be a way to protect ideas, but the inventor has no money to go to law when called upon to defend himself.

I am now working upon ideas pertaining to a rotary gasoline engine, also a device for launching lifeboats in heavy seas and a life-saving device for use in the tall buildings when fire escapes, ladders, and all other means fail. It is remarkable that I have not already fallen in general use, but it is not, and as usual the device is of quite simple construction and of genuine merit.

You should reprint Mr. Kennedy's letter  
Cleveland, O. HOWARD BURN

### The Falling Elevator

To the Editor of the SCIENTIFIC AMERICAN

My attention has been called to an error in the issue of SCIENTIFIC AMERICAN of March 8th. On page 82 you say: "It is interesting to note that the falling distance is four times the stopping interval. Mr. Killiphouse will, during the latter interval, have his weight increased fourfold. Such is not the case. His weight will be increased fivefold."

Suppose the falling interval is 400 feet and the stopping interval 100 feet. Suppose a man weighs 100 pounds. Work done by gravity on man in total descent =  $100 (400+100) = 50,000$  foot pounds. This must be absorbed in the latter interval. The pressure of man on elevator =  $50,000$  foot pounds divided by  $100$  feet =  $500$  pounds. If the man's weight is 150 pounds he will "weigh," during the stopping period, 750 pounds.

This is supporting the stopping acceleration to be uniform which of course it can not be, for if his pressure were to change from 0 on the elevator to 750 pounds suddenly, he would collapse. Hence, as you point out, the negative acceleration must increase gradually. This will make the pressure of a 150-pound man during the last 750 pounds during the latter portion of the stopping period.

Atlanta, Ga.

### The Mississippi Problem

To the Editor of the SCIENTIFIC AMERICAN

I saw some articles in your paper discussing methods of improving the Mississippi River. There is one fact about the Mississippi to which you do not seem to attach any importance, and that is, it is a self-bearing stream, which should not be left out in any plan for the control of the river. It is, as you say, my pretense to regulate the quantity of water in the river by retaining in reservoirs, in the upper sections of the river, enough water to prevent overflows in the lower sections. Every inch in the flow of the river is carried in carrying capacity, not so much because of the volume added to the mass of the water, but because of the increased speed of the current. I saw observations made by an engineer at New Orleans which showed that at high water, a rise of twelve inches doubled the flow of water passing at New Orleans. As a difference of more than one foot at New Orleans would not have been sufficient to prevent the river from overflowing in 1912, reservoirs having the capacity of preventing the river from overflowing in that year should have been extensive enough to retain considerably more than one half this water that drained into the river, and this would require the condemning of a territory larger than several States. It is clear enough that the capacity of the river to carry water is not increased by the levees to increase this capacity, but it is not clear that levees are the only means which can increase the water-carrying power of the river. The effect of levees is to increase the thickness or depth of the water; the measure of the increase is from the level of the land to the banks of the river to the top of the levee; if there were no levees, the same thickness or depth of water would be secured by removing the required number of feet of earth from the bottom of the river. Now it is certain that it is absolutely impossible that so much water should be stopped every year.

It is likely that you have your own means only to protect the river from overflow, it is clear that to meet such a plan, there is something else to be done, but the foundation of the river is the water of the river and the river and the

tributaries. The only manner in which money can be profitably expended by one State in controlling this river, is by building levees, but with the general Government, the case is very different.

The general Government can utilize the natural law which governs the amount of sediment water holds in suspension, depending upon the motion of the water and on the velocity of that motion. If a given amount of earth be placed in the bottom of a vessel containing clear water, and the water be quite still, it will remain clear; none of the earth will rise into the water, all will remain at the bottom of the vessel. If the water be stirred and made to acquire a motion, it will take from the bottom and hold in suspension an amount of earth proportional to the velocity of the motion, the amount of earth in the bottom of the vessel will be decreased and the depth of water will be increased. If water resting on earth be perfectly still, it will become clear, but if the water acquire motion, however slow, it will contain sediment. Now the amount of sediment water will hold in suspension is in proportion to the velocity of the motion of the water, in order to deepen a silt bearing stream, it would be necessary either to increase the velocity of the current without increasing the amount of silt draining into the stream, or to diminish the amount of silt draining into the stream without diminishing the velocity of the current.

Surface drainage of rain water carries with it quantities of the earth over which it passes. Such water having all the sediment it can carry possesses no scouring power; it cannot deepen a stream, it may even cause a stream to shoal if the current be checked as, for instance, by the work at the Northwest pass.

Much of the sediment in the Mississippi comes from the amount of the land which the water carries. If the water were drained this water would be clear. While the Missouri would be deepening it would continue to discharge much sediment in the Mississippi and this river would not deepen at once, but when the current would have deepened sufficiently, its water would become comparatively clear, and the water coming into the Mississippi as clear water instead of as muddy water, would diminish the total quantity of sediment in the Mississippi, and the river would deepen in consequence. I mention the Missouri because of the quantity of mud it discharges, but the Ohio should not be overlooked, since this is the river which furnishes the water which floods the lower Mississippi.

Large quantities of water come from the Mississippi compared to the territory which it drains would seem to indicate that the rainfall in that territory is not sufficient. If this territory were the drained in the local source of the land, all that portion of the land behind the side and the surface would become more or less porous and would retain moisture to increase the yield of the land.

Deepening the river by means of diminishing the quantity of sediment in the water would deepen the channel at the mouth for ocean-going vessels.

There is a manner in which the deepening of the river would bring in returns enough to repay many times over any sum that might be expended. There are quantities of land, extending in some places more than a hundred miles in width from the Mississippi which, from having been moved by the floods of the river for generations, have become elevated by the silt deposited on them. These lands cannot drain into the Mississippi river at high water. As much silt was deposited near the source of supply than at a greater distance, the lowlands along the river have a gradual slope to the Gulf, so that by building levees which prevent the river from directly overflowing land behind the levee, this permits the draining of these lands into the Mississippi at points below. Above Red River, land on the Mississippi can not drain directly into the Gulf, but must return into the river. If the river were deepened so that at the highest point it could be reached, it would be as little as ten feet below the highest point it reaches now it would be difficult to estimate the gain that would result.

Thibodaux, La. JULIUS LAFORCE

### A Plan for the Patents

To the Editor of the SCIENTIFIC AMERICAN

Were all improvements to cease with the present day, all inventions to end, then an unjust, mischievous law that would deprive the inventor of his well-earned "monopoly" must be passed with impunity; for it would only rob one of the means of the nation, the men of progress, those men who have made the world better, living cheaper, convenience greater.

But will men of brains, men of genius, men of inventive talent, spend months and years of study, but to be disappointed, impoverished, and to see their machine for the use of mankind, some valuable process by which commodities are cheapened for the use of the country, when the patent laws will not guarantee them at least the pecuniary patronage as the result of years of disheartening labor? I speak

from experience as well as from observation. There are hundreds of inventions today that have never been patented by their inventors, and they want to know the knowledge of great value, inventions that rightfully remain undisclosed to the public. And why? Why? Because the public says: "We will take your invention and give you no just reward for it, and you want to study and labor." And the inventor replies to the public: "Keep your money, and I will keep my invention." The pressure of ignorant opinion might cause the enactment of less effective patent laws, but neither the public nor the inventor would be benefited. I would disclose his invention. And who is the greater loser? The inventor who must needs get his livelihood by means other than invention, or the great public, which never benefits by some improvement in, some commodity, which never even knows what benefit it has derived itself of?

I say the patent laws are not strong enough. We should have a patent law that would make it the duty of the Government to prevent infringement of patents without putting that burden upon the inventor. And we should have negotiated between the nation a universal patent law, whereby a patent might be taken out (at an additional not prohibitive cost) to cover all countries.

Washington, D. C. WILLIAM EDWIN EMMETT

### Certain Unrecognized "Patent Rights"

To the Editor of the SCIENTIFIC AMERICAN

Many inventions are produced almost simultaneously by parties having no knowledge of the other's doing, in which case the second inventor faces rather poorly under the present patent awards. In an interference suit the Patent Office awards priority of invention to one party, and will grant patents on their specific details to the other contestants who will be subject to the broad patent. This case has happened many times in many cases of merit and the second inventor's rights?

Most inventions of merit are worked out practically, often at great expense, and frequently marketed before a patent application is filed. When two or more inventions independently become equivalent at various times about the same time they may both be said to advance the art substantially equally. In such a case if the losing party in an interference shows that he would suffer by prosecution of the case, it seems to me that he should be not be allowed a license, secure by compulsion if necessary, under the master patent?

Probably in the future, inventions most beneficial to the community will be the result of careful scientific development. Instead of how much the work and thought of one person, an industrial advancement will evolve from experiment and elimination conducted by men in collaboration. The industrial and experimental laboratories of corporations, colleges and scientists will no doubt contribute most toward industrial progress.

If several well-equipped organizations are scientifically working to improve similar products, supply the same public demand, or open a new field, it will in many instances obtain substantially equivalent results. In such cases there will need to be provision that a technically second inventor be not deprived of his invention to his financial loss.

One of the risks in developing an invention is that someone else may be first and by a controlling patent absolutely prevent its use. The master patent may even issue subsequently to the patent dominated, provided it was filed before or within two years of such patent.

The parties adversely affected have no redress, but could receive equitable treatment by means of a compulsory license granted on reasonable terms. Would this not remove a certain speculative feature from the field of industrial development and make it a sounder business undertaking?

Another feature is that an inventor of a revolutionary improvement may find his progress blocked unless he engraves license to allow other inventors to use his name. Mr. Mithel, (Note SCIENTIFIC AMERICAN, November, December 28th, 1912.) A logical or almost obvious improvement may be patented to someone else who endeavors to exert undue tribute for the patent law, but it is not clear that the inventor of a new and valuable invention or those of much or little potential value to the country's industries.

Reverting to the evolution of inventions by the collaborative work of employees of corporate bodies, can we not find a way that the inventor of a new and valuable invention produced by experienced scientists, engineers and mechanics in the employ of an incorporated body. The patent law does not recognize such corporate inventing, and of course if it did should carefully protect independent inventors. Ottawa, Canada. F. D. WITKOWSKI.

## Brucker's Balloon Trip Across the Ocean

By Our Berlin Correspondent

THE daily press recently published a notice that the scheme for the transatlantic balloon expedition originated by Joseph Brucker, at the beginning of 1910, had been abandoned. Undoubtedly among the members of the expedition (Mr. Brucker, Dr. von Sauer, Capt. Nordens and Dr. Alt) were said to be responsible for the fact that the original plan of crossing the ocean with a dirigible, though with the aid of trade winds, had to be given up. However, some of the members were so greatly attached to the idea that Joseph Brucker made up his mind during the present spring to try the passage single-handed by means of a spherical balloon from the Canary Islands.

The balloon destined for this transatlantic trip was constructed and equipped in the relatively short time of six weeks and on February 24th performed a trial flight attended by representatives of the Bavarian military authorities. The balloon, 7,200 cubic meters in capacity, ascended on its stroke of 12.30 and after reaching in a short time a height of 2,500 meters, sailed between two thick cloud strata toward the Inn Valley, landing at 4 o'clock in the Chiemsee district.

Special importance is attached to the sprinkling arrangement designed on plans by Mr. Brucker and Dr. Alt of the Munich Meteorological Institute. This arrangement consists of rubber hose and is intended, in the case of intense sun radiation to sprinkle and cool the balloon with a spray of water thus preventing any undue expansion of the gas.

After this successful trial trip, the balloon Richard II was transported to Tenerife from which place according to Brucker's calculations, the cross-ocean trip will last six to eight days at the utmost. The basket is seaworthy and has been equipped in accordance with such a long trip.

## Protection of Ocean Liners by Subdivision

THE two accompanying illustrations, showing the inner skin which has been built into two notable ocean liners one the "Olympic" already in service, the other the "Imperator" which is about to enter the transatlantic service, prove how quickly the White Star Line and the Hamburg American Line have built into their ships the great lesson which was taught by the sinking of the "Titanic." Within a few days of the discovery of the loss of that ship, her sister, the Olympic, reached New York on her first voyage after six months reconstruction at the Belfast yards. At the time of the loss of the "Titanic" the SCIENTIFIC AMERICAN pointed out that the most important lesson of the disaster was not so much the shortage of lifeboats, as the fact that the "Titanic" herself was so little qualified to serve as her own lifeboat in case of serious injury and remain afloat until her passengers could be transferred to some receiving ship summoned to a rescue. We drew attention to the fact that the "Great Eastern," launched over half a century ago, embodied in her under water construction certain principles of sub-division which rendered her so safe a ship that she could in all probability have passed through the ordeal which sank the ship of fifty years later date. The "Great Eastern" was built with a complete inner skin, with longitudinal bulkheads throughout the engine and boiler room spaces, and with bulkheads, both transverse and longitudinal, which were carried up through the full height of the

plated structure of the ship to a level about thirty feet above the water line.

It was shown that, while warship constructors had retained and developed the features which made the "Great Eastern" a ship so difficult to sink, in the merchant marine there has been a gradual elimination of

The balloon in which Brucker hopes to cross the Atlantic.

The seaworthy basket of Brucker's balloon.

these elements, until nothing was left but the transverse bulkheads and the double bottom. We suggested that future ocean-going steamships could be rendered reasonably secure against sinking by building them with an inner skin and carrying the bulkheads to a reasonable height above the water line.

As the result of the Government investigations in this country and in England, and of the meetings of the various committees appointed to investigate the subject of sub-division, the principles to which we drew attention at that time have been broadly accepted. The White Star Company withdrew the "Olympic" from service and sent her to the Belfast yards, where alterations have been made which have cost the company about \$1,000,000. These changes, which have involved the working into the structure of the ship of an additional one thousand tons of steel, are as follows:

To the original three transverse bulkheads, an additional bulkhead has been added, dividing the ship into seventeen separate watertight compartments. The original height of the top of the bulkheads amidships was about ten feet above the water line. In the reconstructed ship about one half of the bulkheads have been carried up to the top plated deck at a level of about forty feet above the water line. Bulkhead No. 1 has been carried up to the foremast deck at an elevation of about forty five feet above the water line, and No. 2 bulkhead has been raised to C deck, one deck higher than formerly. Below the water, steel watertight flats have been built, covering the space between the stemhead and bulkhead No. 2, and forming two entirely separate watertight compartments. No. 3 bulkhead extends to B deck, No. 4 to B deck, No. 5 to B deck, No. 6 bulkhead extends to B deck, as does also bulkhead No. 10 and the new bulkhead known as No. 12A. Bulkhead 13 also is carried to B deck. No. 14 reaches B deck and No. 15 extends to D deck. The two after compartments are covered below water by watertight flats or deck near the water line. These changes more than conform to the suggestions made by the Senate committee that investigated the loss of the "Titanic."

A complete inner skin has also been built throughout the length of the boiler- and engine-room spaces, by carrying the floor of the ship up to the full height of the main frames, to which it is everywhere strongly riveted. The outer and inner skins are connected by a series of intervertical and longitudinal frames and each double side wall as thus formed between two transverse bulkheads, is divided into four separate watertight compartments by a central vertical and a central longitudinal diaphragm.

To assist in ridding the ship of water in case of injury, an eight-inch pipe which extends the whole length of the ship has been added to the drainage facilities, and it has connections which enable each tank top to be drained independently. This pipe leads to its own independent pumping plant.

Watertight electrically operated doors, all of which may be closed from the bridge are fitted in all the extensions of the bulkheads. It should be mentioned also that in the two bulkheads which intercept the working airway (which latter proved a serious factor in the loss of the "Titanic") watertight doors are provided.

All of the bulkheads, old and new, and the bulkhead doors, have been greatly strengthened by riveting upon them additional frames and angle irons, their strength being estimated for the maximum possible submergence of the ship.

At the time of the loss of the "Titanic," work on the construction of the "Imperator" of the Hamburg American Line, had not progressed so far that it was possible to introduce additional subdivisions designed to protect the ship against an iceberg collision such as is felt the "Titanic." The "Imperator," as at that time constructed, was provided with an inner skin, in the shape of the inner walls of the coal bunkers, which extend throughout the full length of the boiler spaces. This inner skin is situated from fifteen to eighteen feet inboard from the outer skin of the ship and, therefore, in the event of the rupture of the outer skin, say by a colliding ship, the inner wall is so far removed as to be beyond any likelihood of injury. This is the method of arranging the coal bunkers which is practiced in all the navies of the world, and it gives great

View of the space between the inner and outer skins of the "Imperator."

Dividing the inner skin (on the right) of the S.S. "Olympic."

## Babylonian Excavations by the Germans

### How Nebuchadnezzar and His People Lived

**By Edgar J. Banks**

THE excavations conducted by the Germans in the Mesopotamian Valley began in 1880, and are still continued. The ruins of several Babylonian cities, Abu Haur, Babel, and those of the Assyrian capital, Assur, have been excavated. The results have been meager in some of the ruins, in others, they have been of the greatest archeological importance. The general oversight of the excavations has been in the hands of a German architect, who has personally superintended the excavations at Babylon, and who has had a large and varied career in Oriental excavation work. He has been in charge of the excavations at Assur, and some of those at Marsh, now in charge of the work at Assur, deserves great credit. The funds for the support of the excavation have been provided by the German Government, and the German Emperor has been a liberal contributor. This German activity in Mesopotamia far surpasses that of any other nation which activity may be due to the fact that Germany has been the only nation which has been successful in the past few years, perhaps with the hope that when the German railroad across the northern desert to Bagdad shall have been completed, this land of many cities and of ancient ruins may be practically German territory.

### The First Excavations and the Results

Alan Habisz small ruin in central Babylonia, and Fara, a few miles farther north, were the first to attract the German excavators, the results at these sites being published in 1930 and 1931 respectively. Alan Habisz trenches revealed scarcely more than the walls of the houses from a middle period of Babylonian history, and the work was soon abandoned. At Fara, however, the work was continued for about nine months with a force of two hundred men. Beginning at one end of the site, the excavators dug a 30 m. trench 10 m. deep and a few yards apart were dug others, across the mound, and whenever the walls of a house appeared they were followed until the nature of the soil made it impossible to go further. The great abundance of pottery, some marble vases, vertical drains of tiles and wells only were discovered. Finally when the system of trenches had been carried the full length of the site, the work was stopped. The ruins of Fara only early came appeared. In the chambers were several large clay tablets covered with primitive cuneiform characters. It happened that the first light rain of the season fell on the 15th of March, and the excavations were stopped by the Turkish government. The inscription revealed the ancient name of the city as Shuruppak, and the tablets were found to be a list of the food which appears in the Gilgamesh epic.

A valuable discovery at Pura was a large arch sewer beneath the city. Though we have long been taught that the arch was of Roman origin, the arch of this sewer was perfect and symmetrical, and from an age not far from 4500 B. C., when the pre-Neutile Mumerians occupied the land. The bricks used in its construction were plano-convex, resembling in shape and also a small loaf of bread, they were burned to a dark red. The plano-convex bricks appear to have been the first burned bricks ever employed.

### Attacking the Elite of Babylon.

Could the excavations have continued a few weeks longer, more remarkable discoveries might have resulted. However, the Germans then turned their attention to the ruins of Babylon on the left bank of the Tigris, 70 miles south of the ruins of Nineveh. The ruins of Babylon had never been quite forgotten. Travelers of every age have described it. Nearly a century ago large square bricks bearing cuneiform inscriptions with the name of Nebuchadnezzar were taken to the British Museum. The bricks were taken from the most reliable source of revenue to the Arabs who have searched among them for bricks. Heliak, a city of 10,000 people, is constructed of them. The court yards of the houses and a large city square are paved with them; they have been employed in the construction of the walls of the palaces of the Europeans, and still the supply seems inexhaustible.

The ruins of Babylon consist of three large and several small mounds. Surrounding them is a ridge of dirt, reaching in places to a considerable height, and supporting the city walls. Herodotus says the walls were 335 feet high and 85 feet wide. Other writers claim that they were from 45 to 55 miles in circuit and that they were surrounded with 250 towers, and pierced with 500 gateways with gates of bronze. Though the

Germans have attempted to trace the walls throughout their extent, they have but partly succeeded yet it seems that the ancient writers were fairly accurate in their descriptions.

in their descriptions. The Arab mounds, Babel, the Tower of Babel, still retain its ancient name. Separate in shape it rises to a height of over 100 feet. Specially here have the Arabs long been digging for bricks. The Uthmans have paid little attention to this mound except to examine the walls which the Arabs have uncovered. Dr. Koldewey believes that an ancient structure which gave rise to the Biblical story of the Tower of Babel stood there. At the base the Arab diggings have revealed the huge arches of passageways leading through the mound, and they have led some scholars to believe that they supposed the famous hanging gardens of Babylon. Others supposed that the overhanging foliage of the several terraces had the appearance of being suspended in the air.

[illegible]

### Babylon a Comparatively Modern City

The antiquities discovered in the Kasr have not been so ancient as the Germans had hoped. Babylon is a modern city when compared with other Babylonian cities to the south. Minnerich King of Assyria from 705 to 691, boasts that he completely destroyed it, scraping even its foundations into the river. It is a fact that little or nothing previous to Minnerich's time has been found. The Babylon whose ruins still exist is the city of Nebuchadnezzar, the palaces and temples the Germans have excavated were constructed by him or by later kings.

An object of interest from the Kasr was found by Arabs long before the Germans began their excavations. It is a large granite lion standing over the figure of a prostrate man. The monument was never completed, and the Arabs have mutilated it by digging deep holes into its sides in their search for hidden wealth. It bears no inscription to tell its age or history. It is the only monument of the Kasr which has been found where it now stands as if to guard the ruins. The first valuable object discovered by the Germans was a black monolith, brought in ancient times as a trophy of war from the Hittite city of Karkameh. It adorns Babylon just as new Egyptian obelisks adorn New York and various European cities. The front face of the stone is sculptured with the Hittite warrior holding a weapon in the air, the second face is covered with the undepicted characters of the Hittite language.

### The Palace of Nebuchadnezzar

Waldenau's palace in the Kasr may be regarded as the greatest of Koldewey's discoveries. Little but the foundations of the palace remain and they are of square burned bricks, each of which bears on its lower face the name and title of the great king. The several hundred chambers of the palace are small—some of them are scarcely larger than a modern lavatory. The palace is built on a high platform, the main line of value. One chamber, much larger than the rest, had on one of its sides a low platform of bricks. This is supposed to have been the throne room and upon the platform the throne of the king may have stood. So thorough was Dr Koldewey in his excavations that he removed the bricks of the walls and the paving of the throne room, now only the place where

There was a sacred street in Babylon leading from the palace to the temple, along which the images of the gods were carried in processions, according to a religious rite. The gateway known as the Ishtar gate leading to the street, is most imposing, and gives us a good picture of how Babylon must have looked. For-

unfortunately it has escaped destruction at the hands of the Arab brick diggers. Whatever its original height may have been, it still stands 40 feet above the street. Its six square towers of burned bricks, mounting twelve feet each way contain on all their sides, one, above another beautiful reliefs of bulls and lions and dragons and animals of fantastic shapes. The reliefs are of brick glazed blue and yellow and white and the coloring is no fresher as ever it was. Each brick of the towers is shaped and glazed separately and so accurately, that the work is picture in brick. The work formed a part of the perfect culture. The art could scarcely be surpassed.

stipendons work done by the

been in Amran, the southern of the three large mounds. There, forty feet beneath the surface, below the accretions of the Arabs and Hebrews and Parthians and Persians who have lived and built upon the site was discovered longed the famous temple of Babylon. Imagine a hole an acre or more in extent and forty feet deep excavated entirely by hand and you will understand the untiring labors of the Germans. It is the first foundation of the temple was found, but the hole is large enough to show the walls and the similarity of the Babylonian temple with its outer and inner court, its holy of holies its secret chambers and passages, etc., to the Hebrew temple.

Vow clay tablets have been found by the Germans at Babylon. Their smaller discs consisted of Purlian robes, potters' weights, some implements like knives, beads, jewelry and similar objects. However in Junqun one of the smaller monuments to the south the Arabs found a large collection of clay tablets many of which came from the Hebrews concerning the Bagdil family I gild it is the Babylonian pronunciation of the name Jacob. The tablets teach that for many generations the most influential brokerage concern of Babylon was in the hands of the Hebrews family of Jacobs. Equally interesting was a clay barrel-shaped cylinder depicting a man in a chariot slaying lions.

The excavation of Babylon has yet come completed. Much of it will still remain forty or fifty feet of later ruins and future results may be of greater value than those of the past.

### The Excavations at Assur

The excavations at Assur the Assyrian ruin now called Sherghat which lies on the right shore of the Tigris about half way between Ninivah and Bagdad, have been of the greatest importance. Work began there in 1904. It is expected that it will be completed in about two years. *Assur was the first Assyrian capital city giving its name to the Assyrian nation before the older Assyrian monuments have been discovered. Assur continued as a sacred city until the fall of Ninivah in 609 B. C.*

# Inventions New and Interesting

Simple Patent Law. Patent Office News; Notes on Trademarks

## A Spring Substitute for a Pneumatic Tire

THE problem of supplying a substitute for the pneumatic tire for the wheels of automobiles is one that is interesting hundreds of inventors and designers of motor cars and anyone who shall succeed in producing a tire which, while having the advantages of a pneumatic tire, shall be free of the disadvantages, should reap a reward which when measured in dollars and cents will more than justify the efforts in this direction. We show a wheel which is claimed in the invention Mr. Axel K. Mills, to be a perfect substitute for a pneumatic tire embodying what the inventor calls a steel cushion and which it is claimed duplicates in operation the resilient action of a pneumatic tire.

The wheel comprises a rim portion which supports a tire portion composed of segmental sections these parts being made of steel. The segmental sections are pivotally connected to each other and are supported on what is termed a compression resistance mechanism consisting of pivoted levers arranged in pairs, the levers at one end being connected by springs and at their other ends operating through thrust links to force the segmental sec-

The "steel cushion" wheel.

tions radially outward. The wheel may have a steel tread or the segmental sections may be provided with sectional treads of hard rubber or other material for the purpose of decreasing the sound.

The operation is shown in the sectional views, wherein it is seen that the resistance to compression of any particular section which may be in contact with the ground is not wholly resisted by the parts of the compression resistance mechanism directly acting on that particular section and this is accomplished as will be noted by the interconnecting springs which operate on the levers of adjacent sections, so that the compression of any one section is resisted by the springs, levers and thrust links of adjacent sections.

We are advised that these wheels have been tested on continuous runs over the roads of New York and the New England States, extending upward of three thousand miles, and that a Ford car upon which they were placed was in good shape after the test and the wheels in perfect condition. For heavy truck wheels the treads may be of corrugated steel.

The effort of the inventor of the wheel was to secure a cushion tire as cheaply as possible from a cushion wheel, the latter being objectionable because of the constant eccentricity of the continuous rim

to the axle or hub. It is claimed for the Mills wheel that the action is very similar to a pneumatic tire in that the effort to road compression is exerted at points adjacent to the point of contact of the tire with the ground, as well as at that point.

## A Single Instrument Range-finder

TWENTY FIVE years ago the British War Office advertised for a single instrument range finder, and this started in-

Range finder comprising two telescopes with a single eye-piece.

ventors activities along this particular line. The first instruments employed mechanical methods and depended on the angling of end reflectors with a micrometer to measure the angles to which these reflectors had to be turned in order to train them upon the object. The failure of these instruments was due to the difficulty of cutting the fine threads required. The stereoscopic principle was then employed and then the refracting prism but the difficulty in the latter was that variations in the wavelengths of the different colors of light produced errors in the reading. Yellow rays predominate if the air is saturated with moisture, red rays if the air be dry, and blue and blue-green rays on a clear bluish day. The refraction varies of course with the predominating color, and as a result there are serious discrepancies between the readings on bright sunlight days and those on dull days.

The range finder we now have under consideration, like the original range finder, depends upon mechanical methods of measurement, but it does not contain the limitations of the original range finder for the reason that machine tools of precision have been in the meantime perfected to such an extent as to permit of the desired accuracy of measurements. The improved range finder consists of two telescopes X and Y, one approximate-

see the image brought in through the lens B of the movable telescope. The movable telescope Y is turned on the axis Z by a fine screw drum P until the object seen through the movable telescope coincides with the object seen through the fixed telescope. The object as seen through the fixed telescope is inverted. When this adjustment has been secured we have a right angle triangle with the axis of the fixed telescope at the base of the triangle and the axis of the movable telescope directed along the hypotenuse. As the base of this triangle is only three feet long, the angle between the axis of the fixed telescope and that of the movable telescope can vary but little from ninety degrees unless the object under observation is very close. If this angle is made 80 degrees 43 minutes the range figures out to 3,022.1 yards. By moving the telescope through the remaining 17 minutes or 1.029 seconds of arc, the range increases from 3,022.1 yards to infinity. The mechanism must therefore be constructed with such mechanical precision as to make it possible to detect an angle of one second of arc. In order to make the apparatus less bulky, prisms F are introduced into the movable telescope so that it can be materially reduced in length, while it has the same focal length as the fixed telescope. In order to permit of using the range finder at night, the variable drum is

Diagram showing how the pumping is done by the eccentric movement of the annular flanges.

provided with radium buttons at intervals representing fifty yards. The ordinary graduation on the drum can be made to read in 10, 15 or 20 yards.

## Improved Vacuum Pump

A VACUUM pump has recently been developed which is unique in that it contains no valves. Instead a novel mechanical movement is employed similar to that of the eccentric of a steam engine. In the body of the pump are formed two annular recesses into which project two annular flanges formed on an overlying plate. This plate, which is known as the "impeller," has an eccentric movement that causes the flanges to roll along the sidewalls of the annular recesses. Like the strap of an eccentric the impeller has a circular movement without revolving about an axis. In other words, each point on the plate de-

The vacuum pump with superposed motor

The impeller and the recessed body in which it operates.

scribes an orbit with a radius equal to the eccentricity of the plate with respect to the annular recesses. To produce this result, the driving shaft of the pump has an eccentric projection that enters an opening in the center of the impeller. The impeller is prevented from revolving on this center by a guide block, adapted to

side in a slot in a fixed part of the motor frame. The eccentric projection may be turned to adjust the throw. The power shaft is driven by a motor mounted above the pump and connected thereto by means of a belt. To prevent clogging of the pump, the base is chambered to provide for water circulation.

The manner in which the pump operates is shown in the diagram. The valve in the annular recess is shown by solid black lines, while the eccentrically moving flange of the impeller are cross hatched. Each flange with its corresponding recess is a complete jump in itself, being provided with an inlet and an outlet port, as indicated by the black dots. The successive positions of the impeller are shown in the diagram. Fig. 2 shows an advance of fifty degrees over Fig. 1, Fig. 3 an advance of sixty degrees over Fig. 2, and so on, the advance being in the direction of the arrows.

Considering first the inner ring it will be observed that as the points of contact progress in the direction of the arrows the crescent shaped spaces on the left hand side of the transverse partition are increasing, while that on the right hand side are decreasing, so that air taken in through the left hand port will be discharged through the right hand port. The same is true of all the crescent shaped chambers produced on each side of the outer impeller flange. The parts are revolved in heavy oil, so that there is no wear of contact. The pump may be used in the laboratory not only for the purpose of producing a high vacuum but also, by leaving the suction side open, for producing a blast for a blowpipe. By reversing the operation of the pump that is introducing water under pressure into it, it may be converted into a motor. In fact, it is possible to use one of the impellers as a motor, and the other as a suction pump, for the inlet and outlet ports may be entirely disconnected. Thus the city water supply may furnish the power to drive one part of the machine while the other is thereby caused to pump air.

### Notes for Inventors

**A Ball for Use as Deposit in Water Heaters.**—In patent No. 1,046,501 (George T. Hickmott of Pontiac, Mich.) shows a water heating device comprising a shell externally heated and having inlet and outlet openings and an inclined partition extending partially across it between the openings. A ball is free within the shell and rolls upon its bottom and also on the partition off which it rolls should be thrown up on the partition by the agitation of the boiling water. The purpose of the ball is to break up deposits of lime on the bottom wall and keep the wall clean and free of coating when hard water is being used.

**A Novel Cheese-cutter.**—In patent No. 1,046,090, to Elie P. Daution of New York, is provided a cheese cutting device having a rod to penetrate the cheese at its middle and a number of independent movable blades which swing upon and are movable longitudinally along the control rod, so that they can be utilized as cutters to cut out slices from the cheese and also as a cover for the cut end.

**Substitute for the "Eyes of Death" Shuttles.**—News comes from Massachusetts that its mill workers are demanding enforcement by the attorney general of that State of the anti-"Eyes of Death" shuttles law. Along this line it is interesting to note the issue of a patent, No. 1,047,087, to Herbert L. Litchfield of Southbridge, Mass., for a shuttle thrower which has a stiff, unyielding shank and a resilient, resilient hook portion at the end of the shank and adapted to enter the eye of the shuttle, the hook portion having at its extremity an open eye and being of such length that the eye of the shuttle is inserted into the shuttle as far as the shank will permit, the open eye of the shuttle is situated above the shuttle in position prepared to receive the throw of the shuttle.

**Base Ball Making.**—As is well known, base balls are covered by two dumbbell-shaped cover pieces. Frederick H. Perry of Beverly, Mass., has secured a patent, No. 1,046,092, for a method of making base balls in which the dumbbell-shaped cover pieces are applied to a ball outer with a layer of cement between the cover and covers and a series of wiping cloths are delivered against the cover pieces to absorb the excess cement which adheres to the ball center, after which the edges of the cover pieces are trimmed and sewed together.

**A Machine that Folds and Inserts Sheets of Envelopes.**—An Atlanta, Georgia, man, William Henry Young, has secured a patent, No. 1,046,707 for an apparatus in which a pack of envelopes are held with their flaps open and a folding machine has a blade which folds a sheet into two parts and then again folds the folded parts and the blade is then engaged with the sheet to insert the folded sheet into the envelope.

**A Sanitary Drinking Fountain.**—The purpose of Patent No. 1,047,792, is evidently to prevent the use of water as a drinking fountain in an unsanitary manner. The patent which issues to H. Mueller Manufacturing Company, of Doughton, Mass., as assignor of John C. Davis of Doughton, Mass., shows a novel and safe drinking fountain for use in public places. It means to supply a secondary discharge of liquid so positioned as to wet a person before his face can come in contact with the water, the nozzle being so designed as to permit the person to drink without receiving a bath.

**An Electric Signaling Glove.**—In patent No. 1,046,225 (Charles A. Schindler of New Rochelle, N. Y.) is shown a glove, a source of electricity such as a battery carried by the glove and has a (electro) audible alarm mounted on the glove and an electric lamp also mounted on the glove, which will react to the source of electricity with the lamp and with the alarm, and spaced contacts for the circuit wires are arranged on certain fingers of the glove and a circuit closing contact on another finger is adapted to engage either of the spaced contacts to close the corresponding circuit so the signals and alarm can be operated at will.

**A Car-Break Shoe.**—In patent No. 1,046,423 to Pittsburgh Brake Shoe Company as assignor of John Jacob Kneiser of Wildwood, Pa., is shown a brake shoe which has an insulating casing formed of wire fabric and in this fabric is a filling of frictional material with the ends of the casing corrugated.

**Some Charles Francis Jenkins' Patents.** The well-known Washington inventor, Charles Francis Jenkins, has recently issued five patents. One, No. 1,047,027, being for a gas engine starter in which there is a main rotating shaft and a distributor shaft with a projecting end and a rotary distributor supported upon such end and telescoping the shaft and revolute thereon with power devices acting between the shafts. Another is for a distributor shaft with a rotating distributor shaft and means for causing the distributor shaft to rotate the crank shaft at will. A second patent, No. 1,047,528, is for a motion picture apparatus involving improvements in connection with the projecting machine film box and film drum with a friction disk on the drum shaft and drum-driving device as specified. A third patent, No. 1,047,529, is for a film box with a projection with an engine cylinder, while a fourth patent, No. 1,047,530, is for an apparatus for providing boxes with doors and including a vertical wheel having a series of peripheral ridges opening into which receptacles are placed and to which they are delivered laterally, the wheel being rotated step by step and the die and plunger being provided for forming and inserting the ridges. The fifth Jenkins' patent, No. 1,047,531, is for a valve which is adapted to be opened by fluid pressure from one side and is combined with devices arranged to lock the valve positively in closed position when the pressure is lacking.

### Legal Notes

**Failure to Testify and the Presumption of Guilt.**—The case of Steinberger v. Hewlett decided by First Assistant Commissioner Billings, presents some peculiar questions. It was an interference between two sole applicants and the Commissioner held that view of the case was that of two independent inventors "It is very clear that Steinberger would fail but it appeared from the record that a joint application was filed by one Bank and the party Hewlett for the invention of the device prior to the sole application of Hewlett, which joint application was abandoned. It was contended by Steinberger in his testimony that he disclosed the invention to the party Bank and that the records of the Patent Office placed in evidence raised the presumption that Bank disclosed the invention to Hewlett. Hewlett advised to present no testimony so that no testimony is presented in his behalf to rebut the presumption claimed in behalf of Steinberger.

The Commissioner said that "where in a case involving the question of originality, as in the case at hand, no witness is available as a witness when the facts in his favor, if any there be, are peculiarly within his knowledge, the legal presumption follows that his testimony would be unavailing and that such a finding of fact is the decision of the Examiners in Chief and held Steinberger to be the original inventor of the issue.

**Recently Adjudicated Patents.**—Of nine adjudicated cases in a recent list, the DeMoulin patent, No. 553,499 for initiation apparatus and system of electricity was held void for lack of patentable novelty in Alexander deMoulin Heister and Co., 100 Fed. Rep. 145. Claim 2 of the Steinmetz patent, No. 560,911, for an alternating current system of distribution of electricity was held void in General Electric Company v. Albee-Heister Company, 100 Fed. Rep. 160. The Baldwin patent, No. 656,874 for an electrolytic gas-generator plant was held void and infringed and not infringed in claims 2, 4, 5 and 6 in Bloomer v. Baldwin, 100 Fed. Rep. 144. The Auker patent, No. 828,164, for discharge valve for steam-radiator was held not infringed and valid but not infringed in Monash-Younker Company v. Van Auker, 100 Fed. Rep. 123. The Aggerton patent, No. 828,404, for a relief device for water supply was held valid and infringed in Eggleston v. Melvick Heister Manufacturing Company, 100 Fed. Rep. 147. The Boldt design patent, No. 39,021, for a design for a bottle was held void on its face for lack of patentable invention in Charles Boldt v. Turner Brothers Company, 100 Fed. Rep. 119. The Evans design patent, No. 41,785, for a design for a lampshade was held valid and infringed in Macbeth-Evans Glass Company v. Rosenbaum Company, 100 Fed. Rep. 154. The Brewster design patent, No. 40,790, for a design for a clothes brush, has been held valid and infringed in Foster & Brother Company v. Tidgen-Tidgen Company, 200 Fed. Rep. 149. The Redwood patent, No. 625,517, for a mangle holder has been held not infringed in Redington v. Office Equipment Company, 200 Fed. Rep. 67. The Wurt's patent, No. 570,416, for a circuit interrupter device has been held, as to claims 3 and 4, void for lack of patentable invention in Condit Electric Manufacturing Company v. Westinghouse Electric and Manufacturing Company, 200 Fed. Rep. 144. The Carleton patent, No. 491,254, for a hair clipper, has been construed and held not infringed in Brown & Sharpe Manufacturing Company v. Cooke Clipper Manufacturing Company, 200 Fed. Rep. 149. The patent, No. 720,064, for printing telegraph receiver, as to claim 12 as modified and limited by the disclaimer filed, has been held valid and infringed in Moore Carving Machine Company v. Lucas Machine Company, 200 Fed. Rep. 77.

### Trade-mark Notes

**"Bona Fide" Refused Registration.**—First Assistant Commissioner Billings in ex parte Eisenstadt Manufacturing Company has refused registration of the words "Bona Fide" as a trade-mark for mugs, boxes, watches, etc. since those words were the initials of Col. James W. Bona Fide, a well known personage in the army and that the goods upon which they are placed are genuine and that the mark is therefore deceptive.

**Tires and Automobiles Not the Same Goods.**—In the case of G and J Tiro v. G J Motor Car Company First Assistant Commissioner Billings has held that rubber tires and automobiles are not goods of the same descriptive properties and that the use of a mark upon tires was no bar to the use of the same mark upon automobiles by another.

**No Appeal to Court of Appeals in Trade-mark Renewal.**—The Court of Appeals of the District of Columbia in My Justice Van Orsdel in the case of the Standard Oil Company of New York, has held that under the provisions of the Trade-mark Act of 1905 no appeal lies to the Court of Appeals from the decision of the Commissioner of Patents refused to renew the registration of a trade-mark.

**Recording Trade-mark Assignments.**—First Assistant Commissioner of Patents Billings in disposing of the petition of the American Telephone and Telegraph Company for an assignment of a trade-mark not recordable, which while purporting to convey the good will of the business obviously retains in the assignor title to a business which is an integral part of the business and is transferred. At the same time it holds that an assignment of a registered trade-mark must be recorded in full because it does not transfer the good will of the business as to the mark set up in the registration, where the goods mentioned in the assignment are so different from the other goods named in the registration certificate, that the business in the one is segregable from the business in the other. It is in considering this question all reasonable doubts should be resolved in favor of recording the assignment.

**World-wide Trade Marks.**—There is a movement on foot seeking to secure the world-wide recognition of trade-marks. How far this will meet with favor among the commercial nations of the world remains to be seen. By a resolution passed at the Newcastle meeting of the Association of British Chambers of Commerce, in a letter addressed to the Secretary of State for Foreign Affairs by the Association's secretary, to press upon foreign governments the necessity of establishing as an international law that "first public use" be the basis of the right of ownership in a trademark of a trade-mark. In one country priority of registration is held by owners, and use antedates the registration. It is proposed that the subject shall be brought up for discussion at the next international conference for the Protection of Industrial Property.

**The Amended Trade-mark Act.** In the amendment enacted and approved in the early part of this year to the trade-mark statute, it is provided that no mark shall be registered which consists of or comprises a device, a trade-mark, a symbol, a trade emblem, colors, flag or banner adopted by any institution, organization, club, or society which was incorporated in any State in the United States prior to the date of the amendment, or which has previously used that name, distinguishing mark, character, emblem, colors, flag or banner was adopted and publicly used by said institution, organization, club, or society prior to the date of adoption and use by the applicant. The effect of this will doubtless be to enable any institution etc., incorporated as specified and having used the mark as set forth in the statute to oppose said present the registration by a subsequent adopter of the mark.

**Dixon's Flake Graphite**  
speaks for better lubrication

**IF you forget to use Dixon's Graphite, you forget your car, and it is on the road to "Has-Been" before you know it.**

Dixon's Flake Graphite removes the cause of friction—metallic contact. The soft, oily flakes cover the metal surfaces with a permanent, almost frictionless, veneer of graphite which, unlike plain oil or grease, cannot be squeezed out. It has been demonstrated beyond question that it prevents wear and saves repairs.

## DIXON'S Graphite Grease

are composed of pure Flake Graphite and best greases. The leading automobile drivers of America have given them their unqualified endorsement. This proves their high quality.

**DIXON'S GRAPHITE GREASE No. 677** is unequalled for differentials and transmissions. It cushions the shock and reduces the noise of the gears.

Many firms in our home-land, lubricating the Motor—Send name and model of car with your request for this booklet No. 245.

**JOSEPH DIXON CRUCIBLE CO.**  
Established in 1897  
Jersey City, New Jersey

dead or dying flume is, of course, but a matter of good housekeeping, but should be carried out intelligently, for a tree once mutilated must stand on for years in mute reproach to the perpetrator of the act. Flaws should be cut off in a line with the trunk in such a way as to present the side of the cut in direct contact with the downward flow of elaborated sap. Start the cut from the underside to prevent stripping the bark and seal the wounds with a mixture of white lead and boiled linseed oil but with the cheaper brands of prepared putty. Where decay has penetrated the tree, clear out all rot matter following into the hardwood until all fungus mycelia have been removed. Form the cavity in such a way that it will enlarge as it recedes from the opening. All pulpit except at the bottom, where it should slope downward and outward to allow the draining of any sap or moisture which may collect behind the fling. Treat the interior of the cavity with the exception of the area near the opening with creosote and fill with cement colored a dark gray with lamp-black, creating the surface well back and even with the outer flume layer and leaving it slightly convex in shape. In large cavities, steel rim foremen should be used and the cement inserted in sections separated with tar so that the setting of the tree will result in a slight opening of the joints rather than in cracking of the concrete. Although filling cavities in trees only results in forming a mechanical support, the process of filling should be carried out along strictly scientific lines, following engineering rules and at the same time doing the work with the clean and precision that a dentist would use in filling a tooth. A filling with cement when not properly made is probably of more damage to the tree than good unless the cavity is thoroughly cleaned and disinfected. The space behind the filling becomes a veritable breeding ground for parasite fungi and insects, resulting in the ultimate destruction of the tree. This is especially true in the case where the cavity are thoroughly covered over with sheets of metal.

The process of boring and supporting trees by an artificial means is one which may be carried to extremes, the danger being that by the insertion of too many bolts of too large a diameter the timbers are weakened instead of strengthened. Bolts should always be placed through the limbs instead of around as bands, and should only be of sufficient size to furnish necessary support. They should be secured with a link midway between the side to take up the motion caused by the sway of the trees. The heads should be counter-sunk and set in tar or asphalt to prevent fungus spores from entering alongside the bolt. It is usually only necessary to bolt together limbs which spring from crevices which have become split or weakened. A single together of two flume with a mass of iron rods is always undignified and usually it is not necessary.

Outstanding trees or groups of trees because of great value by reason of their size, beauty, location or historic connections, but they are usually worth far more to their owner and to the public at large than merely what corresponds with those virtues and the matter of prolonging the life and beauty of fine old trees becomes well nigh a matter of civic duty in various cities, and cannot be too strongly commended.

### How the Indiana Harvest Wild Rice

A REPORT from the American consul at Kingston, Ontario, gives a graphic account of the wild rice harvest, which was in progress at the time of writing along the shores of Rice Lake, lying a few miles north of Oshawa. Here, as in some parts of southern Canada, and in Minnesota and Wisconsin, the gathering of wild rice is the peculiar prerogative of the Indians, who from time immemorial have used this grain as one of their principal foods. In the fall, it is the whites. In plow season, it was a common food of the European settlers, espe-

cially those engaged in the fur trade. In more recent times it has come to be regarded as a luxury by white people, as it sells for two or three times as much as ordinary white rice. In this country Chicago is still an important market for wild rice.

This plant (*Zizania aquatica*) is, of course, quite different botanically from true rice. It has a long black grain, and hence is sometimes called black rice, but it has scores of other names in English French and the Indian tongue. According to Dr. Jencks, the principal authority on this plant, "more geographic names have been derived from wild rice than from any other natural vegetable product throughout the whole continent." The Menominee Indians derive their name from it. It is the most nutritious cereal in America and many attempts have been made to extend its cultivation but with only much expense. To the average American it is probably less known as a favorite food of wild ducks and other water fowl.

In harvesting this grain the Indians use the same simple methods that were followed by their remote ancestors. We quote from the consul's description as follows:

In gathering sheaves are laid in the bottom of the canoe and a start is made for the rice beds. A man sits in the bow of the boat and paddles while his helpmate takes up a position in the stern and with the aid of two stout sticks breaks the stalks over the canoe and thrashes the rice into the bottom of the boat. This continues until the boat is nearly full when the rice is taken to shore and spread out to dry. After a few hours in the hot sun the grain is ready for parching. This is usually done by the woman who places it in a large iron pot and heat it over a slow fire, stirring it constantly until it is parched. It is then ready for thrashing. This is done by one of the men putting it in an iron pot or large wooden bowl, beating out a bag and with his hands on his feet and fringes that flail about his ankles, he jumps on it until the grain is separated from the chaff. The last operation is that of sifting. The rice is poured into bushel baskets, in small quantities, and squatted down in front of the tents on the shore, under the trees, or in places where there is a good breeze the women gently shake until the chaff is separated from the grain and is blown away by the wind. Crude as it may seem it is exceedingly effective and the work is accomplished clean throughout the whole process.

### Protection of Ocean Liners by Submarines

(Continued from page 238)

security throughout the central portions of the length of the ship against flooding of the boiler and engine room spaces. The new submarine that has been put into the Imperial German navy for the construction of an inner skin, from 3 to 4½ feet from the outer skin which extends from the bulkhead at the forward end of the boiler to the promenade, in the event of flooding through injury. An additional precaution has been the construction of two large triangular tanks aft of the peak tank, which extend the full width of the ship and are closed in by watertight steel floats, approximately at the load water line. We present a photographic view of this work, which is in progress, in the event of flooding over the skin at the bow of the ship and at the right the new interior skin. It will be noted that the heavy framing of this inner skin is well calculated to stand heavy work in pressure, in the event of flooding through injury. An additional precaution has been the construction of two large triangular tanks aft of the peak tank, which extend the full width of the ship and are closed in by watertight steel floats, approximately at the load water line of the ship.

Both of these companies are to be congratulated upon the promptitude with which they have applied the lesson of last year's disaster, and the very thorough manner in which the two great ships have been made better sailing against sinking through under-water damage of any description.

**Esterbrook Pens**  
Relief No. 314

It is an extraordinary pen that adjusts itself to any desired slant and writes smoother than the old goose quill. Made of special alloy of metal—won't corrode—and finished like a gold pen.

## Foreign Dreadnought Developments

WITH the exception of the United States, France is the only naval power of any stand out which announces the characteristics of her new warships to the public. In the majority of cases, however, the details leak out by some means or another, and in only a very few instances are the main features of large ships now under construction known.

The most striking point in recent dreadnought development is the increasing size and power of the gun. The British navy was the first to abandon the 12-inch gun as the main armament of dreadnoughts, and four battleships are now in commission—Orion, Titan, Conqueror, and Monitor—each of which have ten of these weapons, firing 1,200-pound projectiles in five center line turrets. The same caliber of gun is mounted in the four ships of the "King George V" class, and the four of the Iron Duke class, now completing. In the gun, it is a matter of inches. The length of the shell has been increased and 200 pounds added to its weight much of the addition being accounted for by an increased weight of bursting charge. Another notable development in British dreadnought design is the reduction of the main battery.

In view of the interest taken in America in the subject of the battle-cruiser, it is important to note that this type is now being abandoned in England. That, at any rate is the way in which the latest development of the capital ship is generally described, but it is equally true to say that the battlecruiser is being abandoned and that in the future only battle-cruisers will be built. The essential difference between the two types is that the battlecruiser has thicker armor, more guns and less speed than the battleship. Thus, to take two contemporary ships, the battleship Iron Duke has a 12-inch belt, carries ten 13.5-inch guns, and is destined for 22 knots, while the "Tiger" battlecruiser, has a 10-inch belt, carries eight 13.5-inch guns, and is destined for 26 knots. The first two battle-cruisers built for the British navy were designed for 25 knots, and the Iron Duke class are the first battlecruisers to be designed for more than 21.

Last year four large armored ships were included in the British program—the "Hibernia," "Harmattan," "Valiant" and "Warrior" and these will represent the amalgamation of the two types. Their designed speed is 25 knots, which if past experience goes for anything will mean a trial speed of 27 knots. They are to carry only eight big guns, but these will be of 15-inch caliber, firing 1,500-pound projectiles, the total broadside will be 15,000 pounds, and their main belts will be 12 inches, or 15 inches thick. It will be seen, therefore, that they will have the same main battery armament of eight big guns, as well as a very high speed while the only battlecruiser feature remaining to them will be the thick armor belt. It is noteworthy that in these ships the disposition of the main battery guns will be in the center line.

The German armaments have not been very happy with their dreadnought designs. The first eight battleships built have twelve big guns each (11 inch in the first and 12 inch in the second four) but only eight in the third four are available for broadside. The next, the Kaiser, and Friedrich der Grossherzog recently completed the number of 12 inch is reduced to ten, but there is a considerable gain in efficiency inasmuch as all can fire on either beam though only over a small arc, as two of the turrets are placed in the center. The next group, those of the Kaiserin class, have twelve 12-inch and although it is understood that there is a full broadside the arrangement of the turrets is not known.

It was not until the 1st of March last that the first German ship carrying a heavier gun than the 13-inch was launched. This was the "König," a 27,000-ton ship, which will have ten Krupp 14-inch guns, firing 1,800-pound shells in five center line turrets, the total broadside being 18,070 pounds.

From the point of view of design, the most interesting foreign dreadnought now projected are undoubtedly the French battleships "Normandie," "Gascogne," "Flau dré," and "Langue doc," which are to be laid down this year. These ships will be 574 feet long and 85.5 feet in beam with a displacement of 23,200 tons, a designed speed of 21 knots, and a maximum range of 12,000 miles of 12-inch of side armor. Their main armament will comprise twelve 14-inch guns, representing a total broadside of 16,080 pounds, and these will be mounted in three quadruple turrets on the center line, there being four guns almost in each turret. There will also be twenty-four 5.5-inch guns and six submerged torpedo tubes. The three-gun turret is now a well-established feature in many navies—it has been adopted by the United States, Italy, Austria and Russia, but the in foreword engineering about to be made by the French authorities will be watched with interest.

The Brazilian battleship "Rio de Janeiro," now completing at Armstrong's works at Newcastle, makes a striking contrast to those French vessels. Originally intended to carry twelve 14-inch guns, the ship was reduced to 22,000 tons, the "Rio de Janeiro" was redesigned at the desire of the Brazilian authorities after she had been some months in hand, and is now to carry fourteen 12-inch on a displacement of 27,000 tons, the total broadside being 14,800 pounds. The guns will be distributed over seven turrets, all mounted on the middle line—two forward (one superposed), two amidships between the funnels, and three aft (the center one superposed). The length of the ship is 670 feet over all and the designed speed 22 knots, but the main armor belt is only 9 inches thick. The anti-torpedo battery consists of twenty 6-inch guns.

Italy has always been noted for originality in war ship design. The "Dante Alighieri" carrying twelve 12-inch on a displacement of 20,000 tons, was the first battleship to be completed and that nation has now in various stages of construction five ships which are to carry thirteen 12-inch. Ten of these are arranged in the same manner as the 14-inch of the "Nevada" and "Okinawa," and there is an additional three-gun turret amidships. The American arrangement referred to is reproduced exactly in the "Morandi" and "Dandolo," laid down in December, but the Italian vessels will differ in having less armor, a designed speed of 25 knots, and a displacement of 28,000 tons. The big advance is to be made in the case of two ships to be laid down this year. For these vessels the Admiralty had under consideration two designs, one showing a ship of 26,000 tons carrying nine 15-inch in three turrets, and the other a vessel of 28,000 tons carrying twelve guns of this caliber in four turrets, 25 knots being the speed in each case. The latter design is stated to have been decided upon. Given another 600 tons these ships would be exactly twice as heavy as the "Dreadnought" of 1900. The Italian favor big ships, and their latest, if they be built, will surpass anything building or afloat, their total broadside of 25,400 pounds exceeding even that of our own "Pennsylvania," which is 16,000 pounds. She can scarcely say the "Pennsylvania" is a vessel of 28,000 tons, but the big displacement must be allotted to the powerful motive power necessary to drive her at 25 knots.

## Life Without Heat

At a time when the heat and vitality that has belated the British Antarctic expedition brings home to our minds in a dramatic fashion the deadly danger that confronts those who brave the terrible cold of the regions of eternal snow and see an additional interest invests the article of an eminent French man who discourses to us on the beneficial effects of cold. In a recent number of the *Revue des Deux Mondes* the late Admiral de Rochemore, who has been a witness of the cold of the polar regions, would seem like the overmastering heat of an intense tropical summer—temperatures which closely approach the ultimate zero of temperature, the awful and unimaginable cold of the Northern seas. For the Norwegians, that human beings (even the French) are a cold-blooded race, that very little heat would kill us, whereas there is reason to believe that we can stand any amount of cold. Judged from the standard of temperature met by every one of life, it is a very big thing of 40,000 deg. Cent. It is seen that we live on a very cold planet—we are not really much removed from the absolute zero of temperature. But although a rise of a few degrees would destroy not only all human life, but every form of life, it is a very small amount that has been conducted which show that life can successfully resist the extreme cold.

Living organisms, whether bacteria and above, have

been plunged in liquid air, i. e., have been reduced to a temperature of -100 deg. Cent., without apparently harming them. This was the "König," a 27,000-ton ship, which will have ten Krupp 14-inch guns, firing 1,800-pound shells in five center line turrets, the total broadside being 18,070 pounds. These facts have found application in the treatment of a disease, which is called "tetanus" or "lockjaw," which is caused by a bacterium called "Clostridium tetani." By subjecting them to extreme cold, they may be kept for an indefinite length of time, and when required for use they manifest their properties unimpaired.

Incidentally, these experiments remove the objection, based on the cold of inter-stellar space, to the theory that life may be transported from one planet to another. We now know that living organisms can survive the extreme cold. Prof. Pfister has made similar experiments on much more highly organized creatures, such as fishes, and has obtained similar results, a fact which leads Prof. Nordmann to suggest playfully that the process may one day be applied to man himself. In that case a way of escaping our troubles when they become too much for us, or when the great universal refrigerator leaves instruction that we are to be awakened in 80, 200 years' time. However this may be, it is certain that these experiments will lead to many applications of importance, and that they are of much interest to the general public.

Among the many industrial applications which have attended the artificial production of great cold, is the ready means it affords of obtaining large quantities of pure oxygen and pure nitrogen. Air consists chiefly of nitrogen, but sufficient oxygen and the fact that they liquefy at somewhat different temperatures has been utilized to obtain them from the air, a method which is analogous to the well known one of fractional distillation so valuable to the chemist.

Oxygen boils at temperature of -182.5 deg. Cent., and nitrogen at -185.5 deg. Cent. This slight difference of eleven degrees has proved sufficient to effect the almost complete separation of these two gases. The pure oxygen so prepared has many important uses, and is of such importance in present day agriculture. Under the auspices of the Ministry of War in France it is found that powdered aluminum in liquid oxygen forms a high explosive, having about twice the explosive force of ordinary gunpowder while the ordinary explosive is sufficient to melt the metal. It is about the same strength as dynamite. This is obviously a discovery which may have important developments.

The purity of the nitrogen obtained by liquefying air has been utilized in the formation of cyanides, which are of such importance in present day agriculture. The other constituents of the air, argon, krypton, neon, xenon and metargon, are also obtainable by this fractional liquefaction process. Neon, which is so rare that in 50,000 parts of air only one part is neon, may be obtained in quite appreciable quantities in this way. It is well known that when an electric discharge is passed through a tube of neon, the tube emits a beautiful glow. The discharge takes place very easily, a difference of potential of thirteen volts between the electrodes being sufficient to produce the glow. Neon is required for air. But in the ordinary way the beautiful reddish glow now fades, owing to the fact that impurities from the electrodes become mingled with the gas. A way of overcoming this has been found in the case of neon, and it is now possible to keep it transparent in studying the behavior of substances at low temperatures is the extraordinary absorption powers manifested by carbon at the temperature of liquid air. It will absorb gases so readily that it is one of the chief agents now used in the production of the vacuum. The impurities in a neon tube are absorbed by carbon surrounded by liquid air, and this method has proved so satisfactory that it has been found practical to utilize neon tubes as cheap illuminants in Paris. It is again useful as an indicator of the vacuum. It is again useful as an indicator of the vacuum.

**Removable Tents Upstays.**—Setting an excellent example in military construction, one of the large Chicago business concerns has just taken delivery of a number of new vehicles in which the upstays in the production of a cleaning purpose. Instead of being attached permanently to the heels and ends of the bodies, the upholstery is attached to boards which in turn are hinged to the body. This is a device which is used in the case of the cleaning purpose. Instead of being attached permanently to the heels and ends of the bodies, the upholstery is attached to boards which in turn are hinged to the body. This is a device which is used in the case of the cleaning purpose.

### Automobile

**Shorter French Salon Scheduled**—At the last meeting of the French Chambre Syndicale de l'Automobile, it was resolved that the duration of the next French Salon be restricted to 10 days, the last one was open 10 days. Waning attendance during the last days and the impatience of manufacturers to return to work, are understood to have prompted the resolution.

**Air Filters for Carburetors.**—Despite the fact that it has been proven that much of the so-called carbon deposit that collects in cylinders is due to dust drawn in through the carburetor, the marketing of oil gases on Modern lubricants are notably free from carbon content. To insure a proper test of a new oil it would be only fair first to fit a comparatively fine screen to the carburetor air intake. It will be found that the screen must be cleaned of accumulations of dust occasionally.

**An Ingenious Oil-level Indicator** Giving indication of appreciation of the thoughtfulness of motorists in general one prominent manufacturer has taken to equipping his cars with an oil-level indicator which short-circuits the ignition current when the supply of lubricant drops below normal. It is nothing more complicated than a tube inclosing a float buoyed up by the oil. The float carries a contact which touches another contact when the float drops, thus short-circuiting the magnet and giving unmistakable indication of the scarcity of oil.

**Electric "Cyclocars" for Berlin.**—For some time authorities of the city of Berlin have been experimenting with a new type of light electrically propelled vehicles. The cars are of mail and a number of the cars have been purchased by the city. The cars are small, they are not unlike the new type of small automobile styled "cyclocar" for the want of a better name, that has sprung into such prominence in England within the past year. They are capable of transporting 400 pounds at a maximum speed of 18 miles an hour the battery being of sufficient capacity to permit a working radius of approximately 40 miles on a charge.

**Worm Drive and Valveless" Engines Abroad —**  
Although development of the worm drive is practically at a standstill in England, where it first made its appearance, it is only just being taken up with seriousness by French builders, who, like the masters generally, have taken to such innovations with avidity and almost without the thorough investigation which invariably precedes British adoption of any new construction. The so-called "valveless" engine—Knight type and others—has also first made its appearance in England, on the other hand, is very much more in vogue on the Continent than it is across the Channel.

**Why Not Paper-maché Bodies?**—Now that paper-maché is used so extensively in other industries there would seem to be opportunity for employing it with profit in the manufacture of automobile bodies. The framework of the body for instance might be built up of netting and light steel braces with the paper-maché firmly pressed into the interstices of the netting. Such a body would be lighter than a steel body, less expensive to build than an aluminum one, and strong enough incidentally. Paper-maché is capable of being highly polished; it is quite porous so that enamel would adhere readily. It is also so pliable that it can be easily pressed into any shape or bent to any angle. It has a tendency to chip or flake off if the wheel metal is abused.

**Revenue from Battery Charging** With the increasing use of electric vehicles for both pleasure and commercial purposes, central stations are paying more attention to revenue charging as a prime source of revenue rather than as a secondary one, and the wisdom of the practice is reinforced by the fact that one electric light company last year earned \$150,000 net from this source alone. The previous practice of viewing battery charging as an excellent "side line" to assist in reducing overhead expenses, is rapidly giving way to the more logical view that it may with profit be made a specialty in charge of qualified experts ready and willing throughout the twenty-four hours instead of during only that time when the central station meters do not indicate the peak load.

**Gasoline Up in England**—Ehobing recent American advances in the price of gasoline, the British Shell International, which supply the bulk of the fuel used in England, have announced an advance of approximately 4 cents a gallon for Shell 11 and 30 cents for Crown. Shell 11 is the new Crown, which formerly sold for 39 and 47 cents a gallon, respectively. The new prices are 43 cents a gallon for Shell 11 and 30 cents for Crown. What is even more remarkable, as it indicates a measure to stimulate a demand for fuel known as Shell 11 which is priced at 30 cents a gallon. The specific gravity of the new fuel is given as 0.728 to 0.735, as against 0.716 to 0.720 for Shell 1 and 0.726 to 0.732 for Crown. The new fuel is known as Prati's asphalt, which has increased its price, bringing them on a par with those of the Shell products. Incidentally, it is interesting to note that the present price of gasoline in South America is 10 cents a gallon and this is sold purposely to attract the trade in the region.

**A Fixed Date for Easter**—This long-mooted question was discussed anew by Camille Flammarion in *L'Astronome*. It is doubtless regrettable that an epoch in the calendar which fixes the dates of so many other events, civil as well as ecclesiastical, should be subject to such extraordinary variations in its time of occurrence. The extreme range is over a month (March 22nd to April

The French astronomer points out that since for religious reasons Easter must be celebrated on a Sunday, in order that it should fall on the same date every year it would be necessary to reform the calendar as a whole—a step that he considers desirable for other reasons. Pending this consummation, however, he suggests that the range in the date of Easter might be reduced to a week, viz., from April 5th to April 11th.

**Relative Land and Water Areas of the World.**—In our school days we learned that water covers three fourths of the earth's surface, and land the other fourth. This statement dates back to a time when very little was known about the distribution of land and water in the polar regions, and needs to be considerably revised in the light of the latest polar expeditions. The estimate of the latest polar expeditions, Prof. Wagner estimates that the ratio between land and water is 1 242, in other words, that about three sevenths of the earth's surface is land, and the rest water. This estimate assumes that only 10 per cent of the surface north of latitude 40 degrees north is land, an assumption that may be considerably revised by the forthcoming expedition of the German expedition to the northernmost regions of the great unknown region north of British America and Siberia.

**Natural History Explorations in Borneo.**—For more than ten years past Dr. W. L. Abbott, of Philadelphia has been exploring the Malay Archipelago, and presenting all his collections in natural history and ethnology to the Smithsonian Institution. The latest annual report of the Institution, which has just appeared, contains a paper by Dr. Abbott, in which he has related that although Dr. Abbott has been obliged, through illness to abandon personal participation in this admirable undertaking, he has engaged the services of a collector and provided funds for continuing the explorations he had begun in Borneo. The field work will be carried on in eastern Dutch Borneo, the natural history of which is practically unknown, and from which there are at present no collections in American museums. A rich harvest is expected.

As Investigation of Anisotropic Barometers has been in progress for the past two years at the U. S. Bureau of Standards, in Washington, and will undoubtedly lead to improvements in the construction of these indispensable instruments. Interventions have been made of a large collection of instruments, from twelve makers. These have been subjected to mechanical, temperature, and pressure tests, and the results have been compared with the results of the best aneroid, which was held at the lowest pressure for 24 hours, in order to observe what is known as the "reep." This is defect in the action of an aneroid when subjected to a sudden and rapid change of pressure, consisting of a slight adjustment of the index to or toward the correct reading. Its determination appears to be the crucial point in ascertaining the quality of an aneroid. One of the objects of this investigation is the development of standard specifications for the purchase of aneroids by the Government.

Capt. Amundsen has received a grant of \$50,000 from the National Geographic Society toward his coming to the north polar expedition. In voting this grant, the research committee of the society desired especially to encourage the use of the ship *Fram*, which is lent to the oceanographic research, meteorological and magnetic observations, etc. Amundsen expects to start north from the Pacific coast some time in the summer of 1914. His ship, the "*Fram*," which now lies at Buenos Aires, is the oldest ship in the world. She is 35 years old, but will be sent through the Passages of the Northwest, as Amundsen has already arranged that she shall be the first vessel, other than a man-of-war, to pass through the big cut. The reversal of the coming expedition will be practically the same as that which made the recent journey to the south. The ship will sail westward, and it is expected that she will drift right across the polar barrier, following the supposed route of the Melville-Bryant expedition and the wreckage of the "*Jeannette*." In this case, the party should pass not far from the pole, and the magnetic observations appear to be certain.

**Fire Produced by Electric Hand Lamps**—Recently the city of Hagen, Germany, which was attributed to an ordinary electric hand lamp of the type provided with a wire guard. The matter was investigated and it was found that the ordinary hand lamp if provided with a 16 candle-power, 220-volt carbon filament lamp could cause a fire if brought into contact with sawdust or other equally inflammable material in such manner that there is little circulation of air to carry off the heat. But no fires resulted from tests of the filament lamps of equal rating. Although in lamps of 25 or more candle-power ignition could be obtained.

**Sterilizing Swimming Pools.**—For the past three years the public baths in the borough of Poplar, London, have been treated with a so-called "electrolytic fluid" which is an oxidizing fluid obtained by the electrolysis of magnesium chloride. A committee appointed by the Royal Sanitary Institute recently investigated the uses of this fluid, and found that it was not as probably harmful as they found them that when enough of the fluid was added to the water to supply one part of free chlorine for every one or two million parts of water, the pool was kept pure and free from odor and there was no tendency for the water to deposit any scale on the floor. This treatment, however, is unnecessary to renew the water often than once in ten days.

**The Electrical Auctioneers.**—Auction sales are accompanied by a great deal of noise, and in order to do away with this an electrical method has appeared in Holland which means quiet promising, and the sales are now carried out in a quiet and orderly manner. The method is by auction, according to the custom which prevails in the agricultural centers throughout the country in the woolly markets. Eggs are auctioned off in 2,500 lots, each lot being placed in a separate bag and marked with a push button and wiring. The seller is stationed in front of a large dial having prices ranged around it from lowest to highest. There is also a large board containing like figures, and the buyer is to select the price and are connected to the same. After the proper announcement of the lot of eggs as to quality and weight, the seller starts the hand slowly moving around the dial. When at any figure, the buyer presses his button and the hand stops. The number of the lot is then up on the dial, and the number is registered by an annunciator. As the hand moves on, the next bidder can register a higher number, and so on until the bidding is finished. The method is said to be simple and without a doubt can be applied to all kinds of auction work.

**Long-distance Wireless Telephony.**—The Paris daily papers state that wireless telephone messages were lately sent over a distance of more than 600 miles from Rome to Tripoli. Wireless telephony does not appear to have made any marked progress until the present time, since the well-known work of Poulsen and Prof. Majorana's experiments in Italy. This latter inventor used a sensitive microphone of his own design and in this way the "terrestrial despatchers" answered 260 miles in the region of Sicily. However, the recent results obtained by Prof. Vangi of the Military Wireless Institution, near Rome, are of a more important nature. He has succeeded in sending a message over a distance of 600 miles from a point at Tripoli, or about 600 miles from Rome. In these experiments he makes use of a kind of telephone hand which the Italian Government has patented. It is called the "Hand Bell." Using this apparatus of his hand he could, with apparent ease, transmit any voice which he wished to hear at a distance of 600 miles. The apparatus he used is not yet ready for delivery.

## End Dump Bodies for Commercial Vehicles

By Ross Babcock, M. E.

As divided as are opinions on the operative cost of commercial vehicles, one view of one mind that truck owners demand the reduction of lift time to the minimum. The attainment of maximum efficiency with any piece of machinery requires its operation at as near to full capacity as is possible, and the elimination of work or movement that is not strictly useful and the motor truck is no exception to the general rule. It costs very nearly as much to operate a truck light as it does to operate it loaded, and where it is not possible with the aid of removable bodies for instance, to reduce the ratio of time spent in idle running to time spent in performing useful work, other means must be adopted. Otherwise it is altogether likely that the yearly losses will be on the wrong side of the owner's books.

Until comparatively recently little heed of specialized body designs has been taken in commercial vehicle builders, though within the past few months this feature has come in for its just measure of attention. One reason for the noteworthy change of front on the part of manufacturers very likely is due to a general awakening to the fact that if out puts are to be increased, the motor must not only help the purchaser by showing him how to use existing designs with profit to himself, but in addition he must suggest new uses for his products or adapt them to uses heretofore served only by horse-drawn vehicles.

In this respect, it is interesting to note that the end dumping body either manually or mechanically operated slowly but surely is assuming the place of importance it undoubtedly deserves. There are abundant reasons why this should be so. (Given sand or coal or broken stone to handle for instance acute sight is not needed to make plain that antiquated unloading methods—shovels and the manual power of a "gang"—scarcely are compatible with the modernness expressed by the vehicle itself. Such methods need not take that virtually all the time saved by the motor truck in making the haul quickly is sacrificed in unloading. Hence it is entirely logical that some means of making up the deficiency be sought for and the dumping body truck represents that means. Already there are a score or more of makers who specialize in the construction of such apparatus, and if the present tendency can be taken as a criterion the ranks of these manufacturers without doubt will be materially swollen in the not far distant future.

There are four general types of dumping bodies, and they are nearly all of the upending variety. Side dumping bodies are not much used, probably because it is so much easier to maneuver a motor truck than it is to maneuver a horse-drawn one. Seldom is space so restricted that it is impossible to back the truck into position.

In designing these dumping bodies, the tremendous power of the screw is understood and has been very liberally made use of. Hence the screw-operated mechanism forms one group by itself. The other

Fig. 1. 1A and 1B.—Motor truck with dumping and "dismountable" body

Fig. 2.—Dumping body elevated by a double telescoping screw

Figs. 2A and 2B.—Telescoping screw details. Fig. 3A.—Plain screw elevator

Fig. 4.—Dumping body elevated by a power-driven plain screw.

three groups may be broadly classified into (1) those that employ screw sort of erect and (2) those that employ chain sort of erect and (3) those that are chain sort of erect and (4) those that are hydraulically operated.

In the first group, the vehicle shown in Fig. 1, and diagrammatically in Figs. 1A and 1B, is interesting, for it not only provides a means of dumping the body with the power of the engine, but the body is "dismountable" as well. For operation, it depends upon a longitudinal screw *A* driven through a pair of gears *B* by the engine. A nut *C* on the screw is in contact with an arm *D* which is permanently attached to the body. The body is mounted on rollers. As it is forced backward by the screw, the first pair of rollers drops into the curved end of the track on the chassis, thus forming a bearing on which the body tilts. When the body is to be dismounted, the truck is backed up to a platform of the proper height and then, instead of dumping into the curved end of the track, the first pair of rollers passes upon the platform and the body continues straight back until it is clear of the chassis, when the arm *D* is uncoupled from the screw at the nut *C*. To return the body to its normal position, the direction of rotation of the screw is reversed by an idler pulley which is brought into action by means of a lever conveniently placed at the driver's right hand.

In Figs. 3, 2A and 2B an altogether different and more novel arrangement of the screw and nut principle is depicted. In this case the screw is vertically mounted on a swiveling joint and driven from bevel gears and chain from the propeller shaft. The screw itself is virtually a double screw, or one screw telescoping into another. Thus, when the body is down, the height of the screw is only slightly greater than the height of the body. The double screw is operated from a pair of bevel wheels *E* and *F*, mounted on a shaft and arranged so that either may be clutched by means of a lever at the driver's seat. Engagement of the bevel *E* therefore causes the sprocket wheel *G* to turn in one direction, the movement being transmitted to the screw through the intermediary of a chain *H* and another pair of bevels, and thus to hoist the body. Engaging the other bevel *F* causes the chain to run in the opposite direction, thus bringing the body down again. The shaft on which the bevels *E* and *F* are mounted is driven from the propeller shaft through another pair of bevel gears. In operation, the inner screw first rotates within the outer one, raising the body half way, when a stop causes the outer screw to rotate within its casing, raising the body the rest of the way.

The arrangement shown in Figs. 3 and 2A is considerably simpler, though it has the disadvantage that when the body is lowered the screw projects above the body quite a distance. It is thoroughly protected, however, and there can be little objection to it unless the vehicle is to be used where the head room is very restricted. In this case the elevating screw *I* is driven by a short inclined chain *J* from a transverse shaft which is driven by a pair of inclined bevels on the clutch shaft. Rotating either bevel serves to rotate the screw in either direction, thus causing the

## The Elements on the Stage

Thunder, Lightning, Wind, Rain and Fire

THE production of thunder lightning wind rain and fire as well as astronomical phenomena has long attracted attention of theatrical engineers and electricians. We have been enabled through the courtesy of the officials of the Century Theater, formerly the New Theater in New York city to present to our readers a unique series of pictures which are of great interest. In passing it may be stated that the stage of the Century Theater is a most remarkable one and is especially adapted for spectacular productions and we hope at a later date to present an article on the stage proper. One of the unique features of it is the great turntable driven by an electric motor thus permitting one scene to be set while the audience is viewing another scene. The revolving stage is not needed in plays where drop scenes and cloths are used exclusively. The turntable was used in the fire scene in "The Daughter of Heaven" a drama of modern China by Pierre Loti and Jodith Gautier which succeeded "The Garden of Allah" at the Century Theater. The big Algerian play with its marvelous scenery and its wonderful sand storm was even exceeded in beauty by the gorgeous setting of the Chinese play. The scenery properties costumes and effects were a revelation of refined Oriental taste.

We need not concern ourselves with the play proper except for the fire scene, which occurs in the second part of the play. The Manchu advance has swept everything before it. Of all the Ming strongholds the palace citadel alone holds out. Gaping breaches have been torn in its walls by the

The three stages of thunder

enemy's artillery but the soldiers of the Emperor go on fighting with unflinching courage. The Empress is anxious to die with her faithful followers but is dissuaded from doing so by the king that if she is able to escape by the secret passage through the tomb of her ancestors she may yet live to see the sovereignty of her son established. Before she goes at the request of her soldiers she lights the great funeral pyre she has built in order that they may meet death at their own hands rather than fall into those of the enemy. The fire becomes brighter and brighter while the defeated warriors throw themselves on the blazing logs. The fire streams up and is set behind the top of the proscenium arch. The manner in which this effect is produced is very interesting involving as it does an interlocking series of effects which result in a most realistic effect without real fire.

The funeral pyre mechanism is 10 feet and is 6 1/2 feet high. It is dragged on a truck to the back of the turntable before the curtains are withdrawn to rise on the walls of burning scene. It is located over a trap so that when the turntable is revolved the pyre is brought directly over an opening in the lower portion of the stage flooring. The pyre is made of an iron frame covered with wire netting and covered with sand and cement. The opening in the floor of the stage serves to carry the base for the smoke and steam and for the artificial light used in carrying out the idea. The funeral pyre is also covered with silken materials such as artificial feathers. In addition to these fringes there are two or more mats which are so

Scaptocon drum for rain and reproducing thunder, lightning flashes and other machines.

Incantation scene. Air is forced through acid, ammonia and perfume absorbers.

## The Wright Decision

To the Editor of the SCIENTIFIC AMERICAN:

In reading the account in your issue of March 22nd of the decision in the Wright aeroplane case, I do not find that you refer to the Gottfried Schröder German patent, No. 77,000, of October 4th, 1894. This Schröder patent involved a wedge-shaped balloon, pivoted at its front end and having a flat underside, and the balloon contained sufficient gas so that the whole aircraft with its contents would be supported by the gas. The aircraft was propelled forward by means of a paddle operating like the screw propeller of a ship and driven by an engine. Transverse equilibrium is maintained by side wings pivoted and inclined simultaneously in opposite directions by means and link connections, and an upright universal rudder is pivoted and connected with a steering handle in such manner that the rudder moved in exact correspondence with the handle when in any direction. This patent appears to show all elements at opposite sides of the plane underside, the balloon in connection with a dirigible rudder. While you do not in your article, otherwise referred to, mention the Schröder patent, it is discussed in an appendix to the brief of Mr. H. A. Toussaint solicitor and counsel for the complainant in the case of the Wright Company v. Herring-Curtiss Company and Glenn H. Curtiss. In which appendix it is said, referring to the German patent, "It is only for a balloon machine. Judge Hand disposed of similar balloon proposals in the Franklin case, saying 'these are all for all lateral planes to dirigible balloons.' The whole problem is an entirely different when suspension is effected by a reservoir containing a lighter gas than air, that there is not the least resemblance between the patents and the patent in suit." It is thought, however, that the Schröder patent is always being interesting in the history of our navigation as an early instance of stabilizing device.

### ONE INTERESTED

[While the Schröder patent undoubtedly does disclose stabilizing surfaces, which may be used as ailerons, it does not follow that the patentee was aware of the necessity of operating the vertical rudder simultaneously with the ailerons to prevent spinning of the entire machine. The Wright brothers were the first to insist on this principle, without it dynamic flight is impossible.—Editor.]

## The Highest Type of Spring Wheel

To the Editor of the SCIENTIFIC AMERICAN:

Referring to the letter of G. F. Fisher in your issue of March 22nd, it is evident that Mr. Fisher is not familiar with the "highest type of spring wheel," since he states that the springs at the bottom of the wheel must necessarily be fixed in an opposite direction to those at the top of the wheel. His statement is true of most spring wheels, but there are wheels wherein the springs are all fixed in the same direction, whether at the top, bottom, side or any point in the wheel. This feature is not necessarily slight, depending entirely upon the strength of the springs used, and in all cases there is absolutely no feature of the springs during the revolution of the wheel except that caused by an irregularity in the roadway. There may be an initial resilience of one half inch for example, that is, a deflection of one half inch in the wheel from the center of the machine, and yet there is no feature of the springs in any direction during the revolution of the wheel in the movement of the car, except as before stated as is caused by irregularity in the roadway.

It should be noted with care, that no movement or resilience of one and one half inches and deflecting one half inch under the weight of the car may be weighted down by loading the machine to any point of deflection from one half inch to one and one half inches and at no point will feature of the springs occur during the movement of the car over an even roadway.

This result is obtained by attaching the springs from one part of the wheel to the other at points found in a line parallel to the axle of the wheel, thus forming a neutral point; thus a given movement in any direction from the neutral point must cause the same eccentricity of the points and the same flexure of the springs.

It should not be difficult for Mr. Fisher to obtain a deflection of a wheel of this description.

—NEW YORK CITY

HARRY E. STUBBS

## Compressed Air as a Protection for Earthships

To the Editor of the SCIENTIFIC AMERICAN:

It is my hope to make some statements in connection with compressed air as a protection for earthships in your issue of September 22nd, 1918. I am, however, a beginner in this line, and I am sure that you will be able to give me the best advice possible.

authorities to undertake a novel experiment more than a year ago." It is further stated that the test equipment on the armored cruiser "North Carolina" proved so successful that our battalions, including the "Pennsylvania," were shipped in the same way.

When, during the Russo-Japanese war, two Japanese battleships were sunk by mines I sent in April, 1904, to the Japanese minister in Washington, and later direct to the Japanese navy, several letters and memoranda in relation to the Japanese Navy Department, suggesting that they make their ships unsinkable by forcing entering water out by gas pressure. At first I suggested only self-inflating (by calcium chloride) balloons, later compressed air for inflating the balloons, and compressed air alone, without balloons. In a letter of April 20th, 1904 I stated that I intended not to divulge the idea until told that the Navy Department did not want it, in which case I intended to use it commercially or otherwise. The letters were acknowledged, and it was stated that they had been transmitted to the proper place. I never received a communication from the Japanese Navy Department, at least none referring to this matter. (A small contribution for the wounded was acknowledged by the paymaster of the navy.)

Three years later we had the "Japanese war scare." At a certain time so much was said about the probability of Japan going to war with the United States that I considered it my duty as a citizen to write to our Navy Department and state that during the Russo-Japanese war I had made some suggestions to the Japanese Navy Department, one of which was to make ships unsinkable by inflating them with compressed air, and whether they compressed air alone, asked whether they wanted to know the other suggestions.

The Navy Department answered: "Washington July 20th, 1907. Replying to your letter of the 15th inst., suggesting the use of gas to force water from compartments of vessels. You are informed that the Board on Construction, to which your letter was referred, reports that the ideas suggested by you are not novel, and are in some cases in connection with working operations. However, the Board is of opinion that the ideas suggested are not practicable nor desirable for naval purposes." (OTTO MEYER, Ph D)

Richmond, Va.

## The Value of Inventions

To the Editor of the SCIENTIFIC AMERICAN:

The word invention literally means anything contrived for any purpose that has not been used or known to the prior art. In a practical way inventions are understood as something designed to add to the human race, make money, and add to the advancement of civilization. Without inventions progress would soon cease and our vast continent would go back to the wilds.

If we were to take out everything in the United States that is founded on invention, there would be little left. If George Stephenson or someone else had not invented the steam locomotive, the railroad systems of the world would never have had their existence. Had Robert Fulton not invented means of propelling ships by steam the ocean transportation companies would not be carrying millions of tons of valuable merchandise from seaport to seaport. If McCormick had not seen the possibilities of the self-harvesting, we would still be harvesting grain by hand. After the coal stove, cotton gin, steam engine and a few other less important machines had been placed in working order, the greater number of the American people thought the world had been reached, and there could be few more improvements made.

Edison, Westinghouse, DeLaval, Marmon, Burroughs, and Knight did not look at things this way. These great inventors believed that the field of invention was as great as the sea in the future as it was in the past. So having this belief and an iron-bound determination these men began working on things that the supposed to be wisest men of the day thought was an impossibility to accomplish mechanically. They were not influenced to give up the job, and after many years of unremitting toil and study these great benefactors perfected the seemingly impossible, which has added millions in wealth to our nation, and simply changed the time of day and trouble.

Thousands of others have responded to this most noble and useful calling, which has kept the wheels of industry turning and the magnitude of commerce expanding from year to year. Not all inventors are profitable to our country or pay the inventor vast sums of money. Thousands of people find in this line because their machines and devices are not practical, or else they have not sufficient means and courage to promote them. I believe no bounds, I believe no limit to the utilization for the young American in this field are as great to day as they were fifty years ago.

If we expect to maintain a steady advancement in progress, it is necessary to apply the knowledge we have gained to the production of other and new devices in striving for still greater things. Having given this work several years of my time, I feel the greatest re-

quisite for success is self-confidence coupled with patience and thoroughness, for we all make mistakes. The greatest mistakes have been made more mistakes than perfection, but the mistakes are worth more than many failures cost. It is well worth our time and money influence in order to make the most out of the talent with which we are endowed.

For this country to continue in advancement, the Government must encourage that will thoroughly protect the inventors to the greatest possible extent. Tunnel Hill, Ga. SAMUEL H. KENNEDY

## The Spring Wheel Problem

To the Editor of the SCIENTIFIC AMERICAN:

Referring to a letter from Mr. M. K. Dumas in your issue of March 21st, please to give me the state that in my humble opinion both Mr. G. F. Fisher and himself are badly off the track in their ideas as to spring wheels. In my opinion a spring wheel is essentially and primarily a substitute for the pneumatic tire, the persistence of which latter, in the face of its enormous disadvantages, is sufficient proof of the fact that as yet the spring wheel is but a dream. Evidently Mr. G. F. Fisher had in mind a type of spring wheel very common in the Patent Office records where the spring is placed outside the rim and the intervening space filled with springs of some form such that they exert most of their force when the rim is displaced, allowing the use of deflection in compression on one side and tension on the opposite side. This wheel would be one in which spiral springs were arranged radially. On the other hand Mr. Dumas has in mind only that form in which the springs are of such form as to offer elastic resistance in all directions in the plane of the wheel combined with the above-mentioned rapid outer ring. Such a wheel is one in which the wheel is a disk with six axles holes in it parallel to the axle and a large hole in the hub. The six axles holes each contain pins fastened into disks on the hub, forming a wheel which can thus be moved in any direction an amount determined by the loss of one of the six pins in the six holes. Surrounding these pins are springs of various forms which are arranged in no matter how many layers (the inventor may be "They may, for instance, have the form of spirals like clock springs. Both these gentlemen seem blind to any other form of spring wheel, whereas the ideal, e. g., the one which most nearly approaches the pneumatic tire is a wheel in which one which can never substitute for it must have a flexible and not a rigid rim. I was astonished lately in going over a pile of spring wheel patents to find one after another with the same old form of the rigid rim, the incapable of slight movement against a spring of some peculiar form, whereby the inventor thought he could produce a substitute for air. In my mind the ideal spring wheel will be one in which the springs are so arranged that a small portion of the rim may be deformed in and only the springs directly under the "dent" be affected. This wheel can strike a stone and pass over it with very little shock since only one or two of the springs will receive the pressure, which can not raise the wheel from its course simply because only one or two springs are not strong enough to sustain the weight, as the wheel will be so constructed that when resting on a flat surface, a large number (say ten) of the spring segments of which it is constructed will actually be in contact with the ground and sustain the weight. This is just the way the pneumatic tire behaves when on the road. The fallacy of the other arrangement of spring wheels is that they are intended to try the experiment, by placing a solid rim on a pneumatic tire and using it. It is as rough as a steel tire when so treated. Yet there is the most resilient form of spring known placed in a wheel. No firm of spring wheel has ever failed to make a solid rim as well as that much added resilience in the vehicle springs themselves, except that they may save the axle to a slight extent. I gravely doubt whether the solid wheel placed properly in the tire to add strength, and in the springing, would not give much better results. In my opinion the spring wheel is not a thing which will be marketed in a small way or remain under a bushel. When it comes, the present demand, and the solid wheel, which is a solid under-matic tire, will be too strong to allow it to stay undeveloped. But it has got to be good. It must be not only a resilient spring but a resilient spring flexible tire. Suppose the spring disk did not have a rim, but was from \$100 to \$200 in diameter, while after three thousand miles of use sold for \$1.00 to \$2.75. As for me I would be willing to wait for it out of stamp steel springs even every one thousand miles instead of the \$1 of a resilient spring disk. I am sure that the ideal "spring wheel" arrives. I will.

Meanwhile many a man can save himself the price of a useless patent if he will try the experiment and apply the reasoning above, and not think air can be eliminated from a right spring wheel. A "lucky twist" called a "resilient spring member." City Point, Va. E. PAUL DU PONT.

## Russia's Submarine Cruiser

More Than Six Times the Tonnage of the Next Largest Submersible

By R. G. Skerrett

THE Russian government is determined to restore the fleet to the position it enjoyed prior to the war with Japan and to that end generous provision has been made for its rehabilitation.

More than once Russia has started the engineering world by her courageous initiative, and again we see this spirit in the submarine cruiser which it is announced the Russian Admiralty will construct. The reader will naturally ask, What is a submarine cruiser? We can answer this best by making a comparison, or, better a contrast. The biggest submarine yet built for the United States Navy is a vessel of something just short of 500 tons displacement submerged, and the craft

gether with the revolving turret forward, will be sheltered by armor varying from two to three inches thick. In the light surface condition, the cruiser is to have a displacement of 4,500 tons. This means that about 1,000 tons of water ballast must be handled and taken into the boat in order to get her ready for under-water work. The designer estimates that the vessel can perform this operation in three minutes, but this sounds too conservative in the light of experience with submarines of one tenth the displacement. It will probably take a good deal longer and the armor and the rapid fire guns will be very helpful while passing from the surface to the under water condition.

The biggest of the sea-going torpedo-boat destroyers to-day average about 1,000 tons, and these vessels have from three to four above-water launching tubes. These horns of the sea make speeds of from 28 to 32 knots, and are absolutely defenseless against an enemy's rapid-fire gun. Here we have a boat of from 4,500 to 5,500 tons displacement, extensively armored, and capable of firing a whole broadside of torpedoes from their sheltered positions below the waterline. But this is not all. A 4,500-ton ship is far easier to drive and to maintain at a speed more nearly her maximum than a lightly built surface craft of less than one fourth this displacement. Therefore, the submarine cruiser, ton for ton,

A Russian submarine cruiser of 5,400 tons displacement.

proposed for the czar's navy is to have a submerged displacement more than ten times as great, i. e., 5,400 tons.

Quite six years ago, Mr. Simon Lake planned and offered to the Russian government a mine-planting submarine torpedo-boat of large displacement, but the cessation of the war between Russia and Japan called a halt upon the project. Nevertheless, that design of American origin may properly be said to have influenced the Russian engineer, Behn Meyer, in this later development of a kindred type, but beyond that the two vessels are widely dissimilar.

The submarine cruiser is to be virtually an under-water torpedo dreadnaught, and she is also to be capable of planting mines while operating submerged. The torpedo equipment will consist of 26 launching tubes with a supply of 60 long 18-inch Whitehead torpedoes. There will be 16 tubes on each broadside with two bow and two stern launching apparatus. The mine-planting equipment will provide for the carriage of 120 naval defense mines. The vessel will have a battery of five 47-inch rapid fire guns for the purpose of repelling the attack of surface torpedo vessels. These guns will probably prove useful in defending the submarine cruiser during the interval when she is passing from her surface trim to a condition of readiness for submerged operations. As a further protection during this period, the inclined and flat portions of the superstructure, to-

We can get a better idea of the general character of this Russian craft from the following schedule of her principal dimensions:

Length between perpendiculars	400 feet
Beam, maximum	34 "
Draught, surface trim	23.5 "
Draught, maximum submerged, to top of turret	39.5 "
Explosive for surface	18,000 I. H. P.
Electric motors, submerged propulsion	4,500 "
Speed, maximum, surface	29 knots
Speed maximum, submerged	14 "

A vessel capable of attaining the foregoing speeds and radii of action above and below water should certainly prove a very formidable adjunct to the coast defense of any country, and it is plain to see that the relatively sheltered waters of the Baltic would provide an ideal field for the operations of a craft of this nature. A submersible cruiser of the present dimensions would be able to weather any gale and to hold the sea for a long period. In fact, the ship is designed to carry more than 300 tons of liquid fuel and be able to run from the Baltic around to Russia's naval base upon the Asiatic shores of the North Pacific.

will be a far more dangerous antagonist than a similar total displacement divided among four sea-going ordinary destroyers. Apart from this, the Russian vessel could conceal herself if she chose, and this the surface torpedo boat cannot do.

Two unusual features of the submarine cruiser are the armored revolving turret forward and the conning tower amidships, both of which telescopes and can be housed within the contour of the protected superstructure. The questionable feature of the design is the employment of storage batteries for submerged propulsion.

The naval defense of contact mines, 120 in number, are to be carried in one of the after compartments where they can not only be assembled, but launched through hatches leading outboard through the bottom. The mines can be planted while the boat is submerged.

The Russians know all too well the destructive power of this form of under-water attack, and a submarine vessel provides an ideal medium for carrying a field secret. The moderate depths of the Baltic lend themselves easily to this form of submarine defense.

The largest submarines or submersibles now under construction abroad are in the neighborhood of 800 tons submerged, and the naval world will await with interest the building and the performance of this Russian cruiser. Every material increase in the size of a submarine adds seriously to the power of action, the rapid submergence and the consequent loss of

# New York State Barge Canal

Completing One of the World's Greatest Engineering Works

By Noble E. Whitford, Resident Engineer

ONE of the chief characteristics of the early years of the twentieth century was the rapid and almost universal substitution of the machine—the product of man's brain—for the work formerly accomplished by his hands.

This statement is no new axiom, but the repetition of a recognized fact, cited here because the subject of this article illustrates its truth so strikingly.

New York State is engaged in enlarging and modernizing its canal—a system of waterways that were begun nearly a hundred years ago, when much of the territory they traversed was still the primal forest. Thus the old and the new stand in such close proximity and the contrast between the two canals is so marked—in circumstance and method of building—that a comparison shows the strides of a century's progress.

Times and conditions have greatly changed since a day, now ninety years past, when the arrival of a boat in New York city from the head of Seneca Lake was deemed of such importance that its owners, two farmers of Tompkins County, were given a public entertainment by citizens of New York and were presented with a memorial cup. This was the first boat of any size to come so far in the interior, and she had sailed much of her course over a canal then building, which was the marvel of the day. Conditions of the time are reflected in the fact that the timbers and cargo of this boat came from the forest and fields near where she was built, her owners were her architects, builders and navigators, her crew was composed of the men who had cultivated her cargo, and even her sails and rigging were manufactured by her owners, the materials for them having been grown on their farms.

When, two years later, the whole of this new waterway was completed, the lowering of the Seneca led a triumphal voyage that extended across the whole length of the commonwealth and lasted for ten days, ending with a pageant in New York city, the like of which had never before been seen on this side of the Atlantic. In half a dozen years and more, the New York canal has been engaged in another great canal project—one of the greatest engineering feats of the time—but there has been no little opposition in prosecuting the work, and its building has been so overshadowed by the contemporaneous construction by the United States of a more spectacular canal, that perhaps it is not strange that so few people, even among our own citizens, appreciate the magnitude and importance of the enterprise which is being rapidly pushed toward completion.

When it is known that the amount of work required in building the large canal (such as yardage of excavation and concrete and the like) is about three quarters of that at Panama, while its length is more than ten times that of the Isthmian waterway, there comes an appreciation of New York's undertaking. It is significant, moreover, that the large canal, including the construction of terminals at more than fifty cities and villages, is being built for about one third the cost of the Panama canal.

The near approach of the final completion is told in certain statements contained in the annual report which the State engineer has recently transmitted to the legislature. He says that the failure of contractors on the Champlain canal has delayed the completion of that branch in 1913, and that the boat to be expected is that it will be finished in 1914. He also intimates that the Oswego canal and the portion of the Erie canal lying east of the Oswego junction will also be completed in 1914, thus opening waterways to Lake Ontario to the coast. He says that probably by 1915 the western section of the Erie and the whole of the Cayuga and Seneca canal will be finished, thereby completing the entire large canal system.

On January 1st, 1919, the value of the work that had been put under contract amounted to \$77,534,644. Of the whole project only about four per cent, in length of the canal, remains to be awarded. The total value of work performed to the same date was \$53,000,000, or 70 per cent of the same. If we consider all contemplated work as under contract, then this amount already done would be a little more than 80 per cent of the whole project.

At several places portions of the new canal have already been completed, and the work there on the Erie canal, for example, is farmed to the new channel as soon as it is completed. One lock has been in commission for three years, although full operating machinery has not recently been installed. Of the finished sec-

tions, the locks probably furnish as interesting features as any. Some half dozen of them had received their electrical equipment last spring, and some of them were so located that traffic was turned through them. At Whitehall, at the head of Lake Champlain one might have seen a good example of a new lock, for this structure was in full operation during the season, passing boats of the old canal dimensions, usually in groups of six, since they were towed up the lake in fleets of a dozen or more.

A visit to this lock furnishes a most striking demonstration of the superiority of the large canal over the old waterway, for the locks that are now passing are but little changed from those used in the original canal a hundred years ago. Entering the power house at the foot of the new lock, we find an electrical equipment arranged in a compact space of a few hundred feet in every particular. It is necessary to keep this machinery running only during actual lock operations, since, within 80 seconds after water has been turned into the turbines lights in controller cabinets on the control buildings that are on the line in readiness now to begin a lockage at full speed.

Probably nowhere along the line of the canal will the march of progress be seen more distinctly and the contrast between the old and the new appear more sharply. This is in comparing the large canal lock tender with his brother of the old canal. The latter with his back against a great balance beam and his feet pressing a cloistered pulley, might have been seen straining every muscle to close one of the gates, then running across a bridge over the lock to close the opposite gate, next racing to the other end of the lock and out upon the gates to raise and raise the valve lever, and after the boat had been raised or lowered repeating the operation all of which had to be performed in a few minutes at end strength at each lockage, and then only 240 tons of cargo had been locked through.

The large canal lock tender at his operating stand near one of the gates, throws successive switches, first to open the gates for the incoming vessel, then to draw in the water of a canal in excess of a mile, or, perhaps, a pair of boats traveling tandem or a fleet of four, with their loads of 5,000 tons or more to the pair or fleet. Another switch opens the valves for filling or emptying the lock, both gates and both valves being controlled from either side of the lock without running over. All of these operations are performed by electrically-driven machinery which receives its current from the nearby power house, the motive power created at the lock furnishing the motive power.

At the present time the completed locks have been kept to determine the average time for performing a lockage. Assuming that the lock is ready for the entrance of the boats, the time required for hauling a fleet into a lock is 7 minutes, and during this time the upper valve are being closed, which operation requires one minute. As soon as the fleet is in the lock, the upper gates are closed, and this takes 45 seconds. The attendant walks from the upper to the lower end of the lock in 14 minutes. The opening of the lower valves takes 16 minutes, and the emptying of the lock takes 5 1/2 minutes, and the opening of the lower gates 45 seconds. Thus the getting of the fleet out of the lock consumes 5 minutes, making the total time for a complete lockage 2 1/4 minutes.

It is interesting to witness the completion of one noteworthy canal structure—the dam that impounds the water to form the Delta reservoir. This dam, which stretches across the upper Mohawk valley with a length of 1,100 feet and a height of 100 feet above the river foundation, is the chief feature of one of the two projects that will add two lakes to the map of the State. The Delta reservoir, or Delta Lake, as the people in the vicinity prefer to call it, is four miles long and two miles wide at the base of its triangular shape. It occupies the basin of an ancient glacial lake. The arrangement of the surrounding hills suggested to the early settlers the name which they gave to the hamlet that nestled in the western part of the valley. This village of Delta has now been obliterated, its site lying beneath the base of the new lake.

The capacity of this reservoir is 2,750,000,000 cubic feet. Although built primarily for supply purposes, its regulating ability will be considerable. The present low-water flow is from 100 to 150 cubic feet per second, but the greatest flow during the season of record is about 8,500 cubic feet per second. It is estimated that the gates are properly regulated, the reservoir will limit all summer floods to about 2,500, and winter floods to 3,000 cubic feet per second, thus

saving much damage to property in the Mohawk valley. Work is now progressing on the second great river valve that at Hocking, which is located in the foot hills of the Adirondack Mountains, when the delta area south of West Canada Creek above this point has an area of about 372 square miles. The dam for this reservoir will be in the middle, not at the structure with concrete core wall. Its total length will be 1,800 feet, the masonry portion being 500 feet long. The river valve, which will measure 14 miles counting both branches has a capacity of 144,000,000 cubic feet. In regulating floods this reservoir also will have considerable influence. The natural flow of the stream has a wide variation, ranging from 110 to 30,000 cubic feet per second. It is estimated that proper regulation will reduce a flow of 40,000 cubic feet to one of 10,000 per second, or less than half the maximum rate.

During the past year or two, several interesting phases have been added to the canal question. Among them the terminals rank first. The State was somewhat slow in beginning that part of its transportation system which a railroad company would consider first, but the work of providing suitable terminals is now being pushed rapidly to have them in readiness for the opening of the canal.

The legislature of 1911 ordered a survey of the Black Hills between Cuthbert and Socie Harbor on Lake Ontario, to determine the feasibility of making that stream a part of the large canal system. A bill to provide funds for this addition received favorable action at the hands of the legislature of 1912, but a measure for supplying additional funds was given precedence, and only one referendum carrying an appropriation may be submitted to the people at any general election. Probably this subject will come forward for public attention later.

Another subject of considerable public consideration is contained in a recommendation recently made by the State engineer to the legislature. The locks will accommodate boats of 42 or 43 feet beam, but two such locks cannot pass in certain sections of minimum water depth, in the stretch of 183 miles between Lake Ontario and the Hudson River by way of the Oswego and Erie canals, there are only about fifty miles of this minimum width. The State engineer has recommended the appropriation of an extra two million dollars to widen these sections, and to construct a new passage for boats of maximum lock capacity from the canal to Lake Ontario and through the Welland canal to all of the Great Lakes. The use of vessels of 3,000 tons capacity or over, would be possible by this change.

Last summer the landing of two parties of scientists from foreign lands over the line of the large canal showed that its fame is recognized beyond the limits of the home country. These parties traveled by private excursion trains and were composed chiefly of representatives of foreign governments, being men who are eminent in engineering and other scientific pursuits. Representatives of the State engineers department acted as personal guides, and much interest was manifested.

## A New Method of Fertilizing the Soil

ANew method of applying chemical fertilizer to fruit trees is proposed by M. A. Adair and he finds that it gives much better results in experiments which he conducted in the orchards of the University of California. The method is to simply spread or strew the chemical fertilizer on the ground at a certain distance around the trunk of the tree, but the author finds that this has a great advantage in that the fertilizing principle does not pass into the ground, but is retained in the soil. The usual method is to simply spread or strew the fertilizer on the ground at a certain distance around the trunk of the tree, but the author finds that this has a great advantage in that the fertilizing principle does not pass into the ground, but is retained in the soil. The usual method is to simply spread or strew the fertilizer on the ground at a certain distance around the trunk of the tree, but the author finds that this has a great advantage in that the fertilizing principle does not pass into the ground, but is retained in the soil. The usual method is to simply spread or strew the fertilizer on the ground at a certain distance around the trunk of the tree, but the author finds that this has a great advantage in that the fertilizing principle does not pass into the ground, but is retained in the soil.

Large concrete in trench, foundation work resumed.

Truss bridge, across canal.

View of pond, as far east, all dam work is done at canal.

Reaches, concrete wall for dam at Hunkley reservoir.

The canal shows at center, Lake Champlain. West, mouth of dam and lock.

Lock No. 1 at Hunkley, center, bridge of canal.

Bridge in substation, section of lock, substation was placed.

Pool between two at Watford Bridge of lock. Concrete arches, working channel within pool.

BUILDING THE BARGE CANAL OF THE STATE OF NEW YORK.

Top of lock and bridge, over dam, 2000 feet in length.

Installation of gate and lock, bridge, at Hunkley dam.

The lock at Hunkley, 1000 feet with lift of heavy and dam, 1000 feet.

Completed dam at the Hunkley reservoir.

## Inventions New and Interesting

### Simple Patent Law, Patent Office News, Notes on Trademarks

#### A Moth-proof Fly Book

THIS importance and value of having a thoroughly good fly book is something that every angler for trout, bass or salmon realizes. Since the earliest days of casting the artificial fly a safe and convenient means of transporting them to and from the stream and of protecting them against moths has been a necessity. To-day, with modern skill and more particularly the adaptation of celluloid to various purposes, we have reached the point where it is possible to make a moth-proof fly book which is in every respect practical. The accompanying illustration shows a book invented by F. J. Cooper of San Francisco. It is constructed on the book-and-leaf principle so that it is possible for the angler to take with him just such flies as he will be likely to need on his trip. The envelopes or leaves are manufactured of a thin linen on the lower two thirds and of celluloid on the upper third. The entire envelope and flap are strongly bound with twine to make them durable. The angler will readily appreciate the value of this celluloid upper portion, for it enables him, at a glance, to select the required fly and avoid the entire necessity of handling flies which are not wanted. It also avoids the possibility of friction, which in the case of the more delicately constructed flies is a matter of considerable importance. On the flap of the envelope is left a space on which the name of the fly may be written. Any number of envelopes may be secured and used as a safe filing place for the angler's stock of flies. The book is provided with a genuine linen envelope for leaders, also a solid leather pocket for other requisites of an angler's trip. Ample space is allowed for six or eight fly envelopes. Being completely inclosed, the flies are protected from moths.

poised by either crank or gears. The bait is thus permitted to attain high speed.

#### A Gearless Automobile Differential

By R. M. Babcock, M. E.

BY way of overcoming the shortcomings of the very common type of automobile differential mechanism,

A moth-proof fly book.

there recently has been brought out by a Detroit inventor a new style of gearless differential in which the problem of obtaining equal distribution of power to both driving wheels has been attacked in a manner

cost, this fact is made plain by the accompanying illustration. In the mean time, however, it is being tested on a heavy commercial vehicle by one of Detroit's greatest axle makers, and the results of the test will determine largely its future.

The construction of devices of a similar nature has been attempted before, as witness the patented inventions of such noted engineers as Thomas B. Jeffery and Alanson P. Brush and others, though in the new gearless differential the principles adopted or adapted by others in attempts to solve the problem have been relegated to the background.

In its simplest aspect, the device is an adaptation of the well known ratchet and pawl mechanism, though it differs from it in that both springs and ratchets are eliminated. The place of the former is taken by gravity alone and the place of the latter is taken by small cylindrical pins which are free to move within peculiarly shaped slots. The device illustrated was developed for use on commercial vehicles, two being employed, one on either end of the driving jackshaft, which is solid and is driven in the orthodox manner by means of a ring bevel gear and pinion from the engine.

The outer member A has its inner periphery recessed as shown, one set of recesses serving for forward drive and the other set serving for reverse and braking. A plate mounting the driving chain sprocket is bolted to this member and serves also as a cover for the mechanism. The inner member B is slotted as shown in the picture and the slots house five cylindrical pins C, C', C'', C''', C''''.

In operation, when the inner member B, which is splined to the driving axle, is rotated, one of the pins rolls around its slot to the position shown in the picture, C', thus preventing further movement of the inner member without moving also the outer member A, to which the driving chain sprocket is attached. The drive thus is dependent upon a single pin. In the reverse direction the other set of pins will come into action.

In order to minimize the jar caused either on starting from rest the pawl catches either end of the jackshaft are set one 45 degrees ahead of the other, so that one eighth revolution of the driving shaft in either direction serves to lock the driving and driven members.

When the vehicle is being driven along a straight road, the pawl comes on each side lock and transmit the power equally to both wheels, provided the coefficient of adhesion between each wheel and the road is the same. Immediately a curve is reached, however, the outer or faster running wheel over-runs its pawl cam and the inner wheel receives all the power. When one wheel encounters slippery roadway, the lack of adhesion between wheel and road operates to release the pawl cam on that side and the drive then automatically is taken by the other wheel, where better traction is obtainable. Under similar conditions with the ordinary type of differential all the power would be transmitted to the slipping wheel and it would continue to slip, performing no useful work. Hence, the gearless differential would seem to be a better equalizer than is the other.

Advertising Device to Show Wear of Stockings.—Most of the wear on hosiery comes at the toe and heel.

A patent, No. 1,000,000, has been issued to the United Demonstrating Machine Company of Columbus, Ohio, as the assignor of Ernest E. Jarns of the same place for an advertising device in which two stockings are spaced apart, and a sliding vibration mechanism between the two, striking alternately the heel of one and the toe of the other, and a further adjustment mechanism for the stockings at the heel and toe.

A gearless automobile differential.

#### Fishing Reel

THIS fishing season is close upon us, and every fisher of Walton will soon be thinking of going over his outfit in preparation for the season ahead. Next in importance to the rod, if not as important as that article is his reel. All who have cast a fly, bait, spoon or fly, know the value of a thoroughly substantial and reliable reel.

In this part of his equipment, as in all things connected with angling, simplicity is of the greatest importance. A reel which has recently been put upon the market is shown in the accompanying illustration. In appearance it is in keeping with the finest outfit, but appearance is not its only good quality, for its mechanism is of the simplest kind, yet it is constructed so as to overcome many of the difficulties encountered in casting, such as the tendency of the spool to overrun the weight of the line at the end of the spool, and the spooling of the line by tumbling the outside layers, for with this reel it is not necessary to touch the line in casting.

The thumbing lever, by which the spool is freed and the brake applied to the center of the spool, make it possible to run the bait at will. When the thumbing lever is pressed down to hold the spool tight, preparatory to the cast, it automatically throws out a crank and gear mechanism, so that the spool revolves freely. After a cast is made to wind in, you merely press the crank toward the reel and this throws the clutch back to action the spool turning with the crank. It is extremely simple. Press the lever and the spool is free. Press the crank and the spool is again in engagement.

The frame of the reel is of Vietnam alloy, with the crank and removable, making the spool and other operating parts readily accessible. The spool is made from aluminum. As a reel for bait casting particularly it is of unusual value to anglers, for upon releasing the lever, the bait easily accelerates the light spool, which is unham-

pered by anything other. Not only are gears eliminated, but springs and friction devices also are wanting, for which reason great claims are made for it. Whether it ever will come to anything remains to be seen, for its manufacture suggests a number of difficulties that it would seem must result in rather high production

cost, this fact is made plain by the accompanying illustration. In the mean time, however, it is being tested on a heavy commercial vehicle by one of Detroit's greatest axle makers, and the results of the test will determine largely its future.

## The Motor-driven Commercial Vehicle

This department is devoted to the interests of present and prospective owners of motor trucks and delivery wagons. The Editor will endeavor to answer any questions relating to mechanical features, operation and management of commercial motor vehicles.

### End Dump Bodies for Commercial Vehicles

(Continued from page 381)

out 11 to travel either up or down raising or lowering the body.

Traveling from the screw and operating mechanism the rack and pinion mechanism illustrated in Figs. 4 and 41 probably is the simplest of all those illustrated. It is so simple in fact that it scarcely requires explanation. The curved rack 12 is attached to the body and operated by the pinion 11 which in turn is operated through a train of gears giving the required reduction. A hand crank connected at 13 serves to operate the train of gears and the motion of the driver is the elevating motion.

In Figs. 5 and 51 the rack and pinion principle also is employed, though the method of application is quite different. The rack 11 is mounted on the body. Rotation of the pinion 16 by means of a crank attached at 17 serves to move the body backward until it overbalances and tips itself. To draw it back into position a chain 18 winding on a drum 19, which is operated through a train of gear wheels set in motion with a crank attached at 20 is employed.

With the aid of a special fifth wheel arrangement the body illustrated in Fig. 6 has been made particularly adaptable for use in constricted areas where it is impossible to back the vehicle into position for unloading. The body is swung around by hand (the fifth wheel is mounted on rollers) and dumped manually through a combined chain hoisting and movable fulcrum arrangement, shown diagrammatically in Fig. 6A. In operation, the chain 21 which is attached to the arm 22, is wound up on a drum 23 through a train of gears set in motion with a crank attached at 24. The arm 22 has a roller at its lower end which travels on a metal track thus reducing friction to the minimum. The body returns to its normal position by gravity.

A somewhat similar arrangement is shown in Figs. 7 and 71, though the method of application of the movable fulcrum is quite different. The arm 25 is pivoted to the body and travels on a track on the chassis, the chain 26 being attached at its lower end and wound up on a drum 27 operated through a train of gear wheels by a hand crank attached at 28. Thus winding up the chain draws the arm 25 to the rear and hoists the body, which returns to its lowered position by gravity alone.

Operating on the rolling fulcrum principle which permits the application of the greatest power at first, with a gradual diminishing of power as the load is raised

Fig. 5A.—Details of Fig. 5. Figs. 6 and 6A.—Swiveling dumping body

Fig. 7.—Elevating gear employing a sliding fulcrum.

Fig. 7A.—Details of sliding fulcrum. Fig. 8A.—The rolling fulcrum.

Fig. 8.—The rolling fulcrum varies the leverage as required.

Figs. 9A and 9.—Details of a hydraulic pressure device.

into position and less effort is required to raise it, the arrangement depicted in Figs. 8 and 8A is unusual and is different from any of the others. The arm 25 is pivoted to the body and operated by the chain 26 running over a chain wheel 21, which is worm-driven from a shaft 22, driven in turn by spur gears from the propeller shaft. The body is hauled down by reversing the motion of the shaft 22 by means of an idler gear controlled by the driver from his seat.

The mechanism governing the hydraulic hoist shown in Figs. 9 and 9A is operated from a countershaft extended at the front end of the rear set. On this shaft are mounted respectively a chain sprocket and a driving clutch. A lever permits the clutch to slide along the shaft and engage with the sprocket. Alongside the rear set there is a countershaft mounted in ball-bearings from which a rotary oil pump is driven. The pump is connected to the cylinder of the hydraulic ram by means of a section pipe 34 leading into the top of the cylinder. The oil under pressure forces the piston 31 up until the top of the stroke is reached, at which point a strike valve opens three ports in the piston, allowing the oil to escape freely into the top portion, thereby holding the body at rest. The actual lifting of the body is accomplished through the intermediary of a flexible steel cable 35 passing over two sheaves 36 and under a central third sheave 37. Thus, for a given lift of the piston the body is raised twice the height. The third sheave acts as a compensating device equalizing the lifting force on both sides of the body. The whole mechanism is firmly secured to the chassis, but in such a manner that it can be detached as a complete unit without disturbing the truck chassis itself.

### Horse Trucking Costs Estimated by a Team Owners' Association

ONE of the problems which the motor truck transportation engineer has to face when he comes to compare motor vehicle with horse transportation costs is the lack of any definite figures on the cost of using horses.

Members of the Team Owners' Association of Boston, which is made up of a hundred or more of the leading men engaged in the trucking business of that city, recently became involved in a discussion over this question, which resulted in the employment of a certified accountant to investigate the subject, and his report was read before a meeting of the association. This report is in part as follows:

"To start with, there are 393 or 396 (Continued on page 344.)

## The Final Choice of the Discriminating Purchaser

After trying out several different types of motor trucks for the past two years, The Atlantic Ice and Coal Corporation, of Atlanta, Georgia, has recently ordered fifteen White Trucks for immediate delivery.

Responsible firms prefer to purchase truck equipment from responsible manufacturers. This is one of the reasons why the final choice of the discriminating purchaser is invariably White.

Another point of importance is the fact that White Owners continue to buy White Trucks. When Whites are used, experimentation ceases.

White Trucks are the most economical trucks to operate.

**THE WHITE COMPANY**  
CLEVELAND  
Manufacturers of Cadillac Motor Cars, Trucks and Taxis

## 29 More G. V. Electric Trucks For the New York Railways Company

The Third Avenue Railway Company received their first G. V. Emergency Wagon in May, 1911. Today they have in all 8 G. V. Trucks.

What is now the New York Railways Company bought their first G. V. Truck in November, 1911. On March 25, 1913, they placed their entire order for new electric truck equipment with the General Vehicle Company, Inc.

The order calls for the following machines —

- 1 1000 lb. wagon with express type body
- 2 1000 lb. wagons with panel bodies.
- 1 5000 lb. panel money wagon.
- 5 2 ton emergency wagons.
- 14 3½ ton trucks with steel dumping bodies.
- 4 3½ ton trucks with platform and stake bodies.
- 2 8 ton trucks with platform stake bodies.

This order represents an investment in G. V. Electrics of over \$100,000.00. Over 100 other public utility corporations, including some in Manila and Rio de Janeiro, use G. V. Electrics and many of these are standardizing on the G. V. product. They can safely do so, for money can buy no better. We can offer you road transportation machinery proven by 12 years' use.

The look of Nature, and the World's side—  
The dog, the man, the world's side.

## Your Week-end, Your Hupmobile And a Breath of Life in the Open

The steering Hupmobile—the car that “runs wherever a dog can” — turns at last into Farmer Hooke’s lane. You remember that Day—the one Perfect Golden Day. It is given to each of us to live and treasure just one such day. Dawn was just breaking—a spring day, the Dawn of a New Summer—when you and Billy and Ned and Dave left the doorway any street and strayed for that Light.

But Hooke, Junior, has beaten you to it. He grins through his freckles, holds to his string and then leads you off through the hickory grove to the hatched-out Lake of your Dreams.

Then, when the shadows are dancing through the hickories and the Sun and hickies, you pile into the Hupmobile, and wing through the trees, reaching back to the city—in actual miles very far from the Lake of your Dreams, but in the Hupmobile—very near.

Yes, who likes the freedom, new and clean from the everyday grind, who likes the perfect day, too, with a Hupmobile?

Yes, who likes the freedom, new and clean from the everyday grind, who likes the perfect day, too, with a Hupmobile? Yes, who likes the freedom, new and clean from the everyday grind, who likes the perfect day, too, with a Hupmobile? Yes, who likes the freedom, new and clean from the everyday grind, who likes the perfect day, too, with a Hupmobile?

Hupmobile “32” Touring Car, \$1000 f. o. b. Detroit  
In Canada, \$1150 f. o. b.

Whisper  
Four-cylinder motor, cylinder 144, inch bore by 114-inch stroke, and inch bore. That means plenty of power, and that means plenty of fun.

Full touring car axle. Wheelbase, 106 in. Tires, 12x16 in.

Exhaust of exhaust, made by 144-inch stroke, and inch bore. That means plenty of power, and that means plenty of fun.

estimated that 10 per cent of the total production was not reported in 1912 and 25 per cent was not reported in 1911 and previous years. The total output would come to 24,125 for 1912, as against 18,710 for 1911 and 12,008 for previous years, making a total output up to and including 1912 of 54,820. The estimate for 1913, based on the report of 170 companies, plus 10 per cent, is 66,514 which represents a growth of considerably more than two hundred per cent. The mean average price of all commercial vehicles produced in 1912 was \$1967.47. The average price of gasoline cars was \$1,948.05 and of electric vehicles, \$2,406.18. The average price of gas trucks in 1911 was \$2,070.16, and in all preceding years combined \$1,665.70, while the average price of all electric cars in 1911 was \$2,739.01, and of all preceding years \$3,369.72.

### Motor Truck Researches at the Massachusetts Institute of Technology.

To the Editor of the SCIENTIFIC AMERICAN: Remarks by Mr. John Hirthle, Jr. in the March 26th issue of the SCIENTIFIC AMERICAN have been noted by this writer.

We believe that the motor truck researches being conducted by the Massachusetts Institute of Technology are very thorough and sincere but as Mr. Hirthle states that the bulk of the support for conducting these experiments and tests was furnished by electrical interests, we are inclined to believe that that was why the electrical figures appear so favorable. We do know that there are over 400 Pierce-Arrow trucks in daily operation in various parts of the country, and some of them cost more per mile to operate than stated in the table published in your February 22nd issue. There are seventy of these trucks under the writer's personal supervision in this vicinity, and they all operate for less cost than mentioned in this table.

If the Massachusetts Institute of Technology were experimenting with old trucks or with new inefficient trucks, the high figures they get for gasoline trucks would be required for them.

From the actual work done by Pierce-Arrow trucks in this vicinity, the tire cost per mile averages less than 5 cents.

Homer C. Rein,  
Manager, Truck Department,  
Harrille Motor Car Company

### Overloading the Motor

By John R. Eastle

THERE is probably no one thing that will need a motor truck to the repair shop quicker than overloading. Over speeding is about equally hard on the vehicle, but a driver always knows when he is exceeding the safe limit in this respect, while overloading is often done unconsciously.

The reason for this is that few operators know accurately the weights of the commodities which they transport on their vehicles. When horses were used this knowledge was unnecessary, for the behavior of a team always shows whether the load is too heavy for it.

A motor truck, on the other hand, will move a load a ton or more in excess of its rated capacity without showing the terrible strain to which it is being subjected. This strain will soon tell, however, and frequent trips to the repair shop inevitably follow.

To avoid overloading of motor trucks or any other type of commercial vehicle it is necessary to know the weight of each package or unit that is loaded on it. In some cases weighing platforms on which the loaded truck can be run are available, but then the tendency would be to "let her go this time," rather than remove part of the load.

There is, of course, always a margin of safety over the rated capacity of a motor truck, but it is not advisable to take advantage of it, and when unusually rough roads and steep grades are to be encountered it is best to "keep the wheels on the ground."

## 26 Girls could not equal one Addressograph

The Diamond Rubber Company of Akron, Ohio, wrote to the Ingersoll-Rand Co., Easton, Penn., as follows concerning their Addressograph Equipment:

"Our largest day's work with the two Addressographs we have, on circular work, ran a little over 42,000 addresses. The largest day's work we ever had before using the Addressograph, was 21,700 addresses by 26 girls."

### A Complete Address Per Second

The Addressograph enables your inexperienced office boy to address all classes of mail matter and forms, such as statements, checks, record cards and clock cards, payroll sheets, etc., at the rate of 50 to 60 per minute. It is a mechanical impossibility for the Addressograph to make a mistake. Each address is clean-cut, accurate and looks like the best typewriting.

### A Modern Card Index

The Addressograph is more than a mere addressing machine—it is a complete card index system. The address plate can be equipped with printed form proof cards for keeping information right on each address plate—vertical sub-dividing tabs can be furnished for arranging the address plates in any desired card index order.

More than 40,000 of the brightest and shrewdest men in the United States profitably use the Addressograph—many of them in your line of business. Let us tell you in dollars and cents just what this efficient machine will save you.

### ADDRESSOGRAPH COMPANY

807 WEST VAN BUREN STREET, CHICAGO, ILL.

NEW BOOKS, ETC.

**THE INTRODUCTION OF RADIIUM.** Belong the introduction of this new experimental lecture delivered at the University of Glasgow by Frederick Soddy, M. A. F. R. S. Independent lecturer in physical chemistry and radio-activity in the University of Glasgow. With illustrations. Third edition revised and enlarged. New York: C. P. Putnam's Sons, 1912.

The previous editions of Mr. Soddy's excellent book on radio-activity have been so fully reviewed in three columns that a detailed notice of this third edition is hardly necessary. We can only repeat what we have already said, i. e. that the book is a model of straightforward and unpretentious writing, that it is not only popular in style but accurate in expression. Mr. Soddy has of course included accounts of the new discoveries and developments in the domain of radio-activity. The technical production of the new radio-activity substances mesothorium and radithorium now have a considerable and growing importance for which reason they are considered at length. We are glad to see how carefully Mr. Soddy handles the subject of the transmutation of elements which has been thrust into public view by sensational newspaper accounts of the late William Ramsay's experiments. On the whole those who take an interest in the new chemistry and who wish to read a concise and yet popular account of the modern chemistry of radium in the field of radio-activity will find Mr. Soddy's book an extremely useful for the purpose.

**THE CAROLINE ENGINE ON THE FARM.** A practical, comprehensive treatise of the construction, repair, management and the use of this great, iron horse, as applied to all farm machinery and implements, with a complete glossary. By Xiao W. Putnam. 170 illustrations. New York: The Norman W. Henchy Publishing Company, Ltd., 1914. \$2.50.

The uses for the gas engine are legion. It is the mechanical horse of the farm, the power for the mechanical man of the neighborhood. It can be used in the house, in the barn, in the field and in the garden. There is hardly any part where there is a man to do the work the gasoline engine cannot be used to advantage. In many American farms this engine may be found that vary in size from one and two horsepower to fifty and sixty horsepower and that are used for almost every imaginable purpose. Just how extensive is this application of engines it is difficult to state with any degree of certainty. To secure accurate statistics is to show the actual number of farm engines in use, but the number must be large. For example, in 1911 three companies alone made upward of 100,000 engines ranging in size from two to fifteen horsepower. Eighteen men manufacturers report that they had sold since starting in business 555,000 engines, while twenty-five firms reported in 1912 that they manufactured for the year over at least 700,000 engines. As nearly as we can determine there are 750,000 engines of gasoline and oil engines in the United States and fully five hundred of these make a specialty of farm engines. Obviously it is time that some book should appear which is devoted to a subject of such vast importance for the farm, machinery to the average farmer means simply ingenious harnesses ropes and binders. Mr. Putnam has performed a useful service in meeting what must be a real demand for a complete farmer's handbook on the internal combustion motor and its agricultural applications. The applications of gasoline engines to farm and domestic work that he reveals are really astounding. We can only wish that Mr. Putnam had omitted the rather flowery praise of his work published on the title page.

**PRACTICAL METHODS OF SAWING DISPO.** For Residents, Home and Institutions. By Henry N. Orison, M. A. M. B. C. E., and H. Burdett Cleveland, Assoc. E. L. Am. Soc. E. L. New York: John Wiley & Sons, 1912. Pp. 162 pp., illustrated. Price, \$1.50 net.

The work is particularly addressed to house-builders and home designers with its elementary technical terminology. It gives detailed practical information as to the construction of a small plant to successfully deal with the average farm or country house. It does not seek to duplicate the sawmill and the trained man in the handling of large problems and unusual conditions. Directions are given for building and operating a mill, and the principles are explained in such a manner as to permit the student from taking them. However, except in ordinary work, a mill may be from directly modern and up-to-date standards, they are at least preferable to the home-walled contrivance as usually used. Radio-sonic friction and sawing fires are dealt with in subsequent chapters. The work takes the small division is given over to estimates of cost.

**ENGLISH SECTA. A History of Nonconformity.** By W. B. E. Selbie, M. A., D. D. New York: Henry Holt & Co., 1912. 16mo., 250 pp. Price, 60 cents net.

In fulfillment of the plan of the publishers, the English University Library series to include within its scope every subject of vital and significant importance. The brief history of nonconformity its origin and progress down to the present time, will be welcomed by the many for whom the English has a real and deep interest.

**ONE-ACRE-TOUR FRACTION.** A book for the man who has the opportunity of making a fortune in a few days. By J. S. Springer, New York: The

Wear Proof—So Error Proof

**THE Warner Auto Meter** does not possess a single wearing point in its speed indicating system. It operates on the magnetic principle.

Every centrifugal speedometer—every speedometer operating on the gyroscopic principle possesses no less than twelve (12) wearing points.

How can the latter begin to compare with the former, how is it prepared in any way to give accurate, intelligent speed indication?

In a nut shell, you have the reason why 95% of all the speedometers made in the United States are magnetic.

The Warner Auto Meter does not have a single wearing point for the simple reason that the speed indicating device consists of but two parts. The first is a magnet and the second a disc which sets over it—provided on magnets. Bearings will not wear appreciably inside a human life. The magnet, revolved by its connection with the flexible shaft to the road wheel, itself exerts a magnetic pull on the aluminum disc. The two do not touch.

Every centrifugal instrument is a complex combination of springs, bars, arms, case and thus, great metal parts. There are no less than 120 wearing parts in each.

The magnetic speedometer is protected by U. S. Patent. Assume that a centrifugal speedometer. It is just what indication of the recognition of the magnetic in transient as the practical, accurate type.

An inaccurate speed indicator is worse than useless. Unless your car has a Warner it is not efficiently equipped. See that it is. It means dollars to you in the wear or keeping an accurate car on the road, gasoline and oil consumption.

Interesting literature and a handsome catalogue on request.

## Safety in Travel

More glowing tribute cannot be paid the accuracy of the modern watch than this—in all the complexity and immensity of railroad traffic hardly a single life is imperilled, or a dollar lost, because of imperfect timekeeping. Remembering then that the

## Hamilton Watch

*"The Railroad Timekeeper of America"*

Master Lewis C. Henry of the Pacific  
Express Company's Broadway Limited  
is in one of the many fast trains  
which carry Hamilton Watches and  
have carried them for years.

is carried by **over one-half (56%)** of the railroad men on American railroads where Official Time Inspection is maintained, it is only fair to assert that the Hamilton Watch has played no small nor uncertain part in ridding travel of one of its greatest dangers—danger arising from inaccuracy of time.

Trains are dispatched on "hair-line" schedules by Hamilton time—because Hamilton time is "travel safe."

Hamilton Watches are made in correct sizes for men and women and sold by jewelers everywhere.

Movements only are \$12.25 and upward. Complete watches, certain sizes, are \$38.50 to \$150.00. Ask your jeweler about them, also about fitting your present watch case with a Hamilton movement.

*Write for "The Timekeeper"*

It illustrates and describes the various Hamilton models and is a book well worth reading if you are thinking of buying a fine watch.

## This chart scratches Electricity from the luxury list

Electricity and electrical comforts—once called a luxury—are becoming a necessity in the average home.

And while the climbing cost of other necessities is putting them in the luxury class the falling cost of electric lighting is making it easier and easier for us all to afford it.

I look at the Chart—it is based on Government figures.

Twenty five years ago, electric light cost ten times as much as it does today. Seven years ago it cost three times as much as it does today.

All this has been effected by the progress and inventiveness of electrical manufacturers and by the enterprise and improved service of electric lighting companies.

One thing alone—the development of the tungsten filament as used in EDISON MAZDA LAMPS—has subtracted *two thirds* from the former cost of electric lighting. Still another

economy is effected by Holophane Reflectors, which *avoid waste* of light by scientifically directing it to where it will be most useful.

Edison Mazda Lamps give you *three times* as much light as old-style carbon lamps from the same amount of current. Put them in your home and you can have as much light—and even *more*—than old style carbon lamps give you and *still* save enough current to operate some of the delightfully convenient electric devices shown below.

*The Guarantee of Excellence on Goods Electrical*

*Electric Wiring Costs Less, Too*

You will be surprised to find how little it now costs to equip your home for all these electrical comforts. The walls will not be marred. Your nearest electrical dealer or your lighting company will direct you to a good electrical contractor. Ask them also to show you the various sizes of Edison Mazda Lamps and the many electrical conveniences for the home, bearing the G-E trade mark.

## The Human Factor in Safe Transportation

NOTWITHSTANDING the many excellent devices that are being provided to secure safety on American railways and the improved conditions of maintenance of track and roadbed, as well as the gradual extension of block signals and other protective appliances, there seems to be a very marked increase in the number of railway accidents each year. In part this can be explained by the increase of operation such as increased speeds and weights, present new problems, and in many cases an attempt to be made to carry on much traffic over track where rails and roadway are not always adequate.

But there is one important respect in which there has been little progress, namely the responsibility of the individual employee. Today it is the human factor that is most growing in any discussion of safety on American railways. The deficiencies of the human factor and especially direct personal responsibility have been established in many collisions and derailments, and in numerous minor accidents. This has been revealed by operating officials. By them the question is often considered one of discipline only in which their efforts have been weakened by the indifference of labor organizations and controllers that secured merely questions of discipline. But it is now realized that by stimulating individual interest and responsibility on the part of the employees, railway operation can be made safer and traffic can be carried by the economies themselves more economically and expeditiously.

Indeed, the matter has a distinct economic bearing. Payments made on account of injuries to persons during 1911 aggregated \$25,070,717 or 0.149 per cent of the gross earnings for that year and for loss and damage to property \$3,978,718, or 1.28 per cent of the gross earnings making a grand total of nearly \$30,000,000 or 2.19 per cent of the gross earnings. This stands for gross waste and expense in the industry, and the further investigation is made using these lines the more is this apparent. With or without such damage suits the railway may in part compensate the sufferers, or by accident insurance or work compensation the injured may be distributed, but it is the responsibility that pays either in diminished earnings or dividends, increased transportation charges, or increased promptness or assessments. Furthermore, to the railway it self the loss of life of a capable employee is at least a temporary derangement of the entire transportation, requiring readjustment that may involve more or less time and expense. As in other industries skilled railway employees are no less an asset than material equipment and they should be conserved with even greater care.

The problem of safety resolves itself into the training of efficient employees and their conservation when once trained. Toward realizing this end there has been within a few years, a distinct tendency toward improved discipline of the employees in transportation, requiring readjustment that may involve more or less time and expense. As in other industries skilled railway employees are no less an asset than material equipment and they should be conserved with even greater care.

It has been brought to the attention of the employees with blunt force that they, rather than the presidents, superintendents and other officials, are the ones to suffer in accidents, that while stockholders might pay, it was the man who was killed and their families who were left in straitened circumstances, that the rail road formulated rules and operating conditions to be observed, and that under no circumstances was there to be any room for error or for the employee to take any advantage for the sake of a few cents taken that might cause the slightest mishap. It was shown to the railway employee that most of the accidents on railroads were

due to their carelessness, disobedience of orders or rules, and negligence.

For example, much trivial matter as projecting nails on platforms, or more particularly on locomotives from freight cars, together with the tracks, are annually responsible for a large number of serious injuries to railway men, and the slightest amount of caution in this respect would save many thousands of dollars loss in wages, many men suffering with serious injury, and many billions properly to pile ties, lumber and other material, to close tracks, to remove objects in train yards over which a freight locomotive might stumble in the dark, to illuminate the interior of engine houses properly, and the like.

The constant supervision and care to prevent house-keeping and maintenance, are responsible for a list of casualties that is striking in its aggregate. But such misfortunes it may be urged are small and bear little relation to the large wrecks in which a score of passengers may be killed or injured. The same condition holds in the direct processes of operation. The trainman may not take the trouble to go back far enough to protect the rear end of his train, the engineer may think he can make time by taking track he is entitled to the track foreman may consider a certain section of line with imperfect ties or poor surfacing will answer, while maintenance of way officials may consider short cross-overs safe, though realizing the fact that the regulation will be exceeded in passing them. In these things if the employee is to be held responsible, the projecting nail on the track, the increased safety for him and his fellows is provided, if the brakeman will go back sufficiently to protect the rear end, whether it means a longer wait or delay of the train, until the engineer is able to call him back, the lives of passengers and employees alike are safeguarded, if the track master will avoid unsafe cross-overs at speeds which he knows will be used, there will be a corresponding gain in the safety of the system.

Obviously it is more than a matter of discipline. If the personal interest of each employee can be aroused, then a great step forward is taken. That this can be done and has been done is shown by the improved results of a number of roads where so-called safety committees have been organized. These committees are formed of representatives of each class of operatives and certain operating officials. They carry on a campaign of education and inspection, call attention to the rules and insist on their strict application, train the employees to the proper conditions that are in any way dangerous, and to suggest means for safer and better operation. They also urge the employees to eliminate from the service those whose conduct is likely to produce loss of life or injury to their fellow workers. Such safety committees are now organized on lines representing over half of the entire mileage in the United States and they have received the most enthusiastic commendation of the railway authorities, as well as of the Interstate Commerce Commission.

## Another Mad Patent Bill

EXORT the tariff and the currency, no subject seems so attractive to the legislative flogger as that of patents. The latest bill which seeks to improve our patent system springs from the fertile brain of Mr. Stephens of Ohio. Its object is to require citizens of foreign countries who may apply for patent registration, or for letters patent, in the United States to pay the same fees as to subject here to the patent and copyright laws and regulations of their own government.

Apparently the practice of law is not complicated enough for Mr. Stephens. He would require patent laws to follow not only the laws of the country, but to acquire an intimate knowledge of all foreign patent practice as well. The judges of our federal courts would have to interpret foreign patent law and to apply them in international cases, although they have difficulty enough in interpreting and applying our own. The Patent Office would be required to keep an elaborate set of books in order to collect taxes and to enforce other burdensome regulations.

Fortunately this spring madness is not likely to be taken very seriously. Investors have reason to be thankful that tariff reform is now again engendering legislative attention.

## Solving New York's Pier Problem With the Model Basin and the Moving Picture

THIS pier problem of the North River has vexed for some years both the municipal engineers and the army engineers. Both bodies have taken opposite views as to the propriety and wisdom of lengthening the beaching spaces for great transatlantic express steamers. New York had hardly said that she desired a group of wharves where she could "dock" her ships when she was long enough for the "Hugoboss" or her sister ship, which was to be the "Titanic." When proposed that plans of these

structures would be built, wherever on the river, the Secretary of War granted permission for the temporary extension of two of the pier docks in the Chelsea section, Fort Clinton, on the Jersey side of the river.

Many then, the chief authorities of the port and other municipal boards have not agreed where the proposed pier should be built, and the time allowed by the Secretary of War for the continuance of the temporary extension referred to is about close to an end. What has appeared to be a critical stage of the situation is recently been relieved by the announcement that the city of New York is now ready to start work on new piers. With that understanding, the War Department has permitted the temporary extensions to remain a while longer.

The present Chelsea piers bound on one side the narrowest section of the North River, and tidal conditions have been radically changed there in the course of the last few decades by encroachments which have tended greatly to increase the force of the currents. The dock authorities of New York have held that the 100-foot temporary extensions to two of the piers could be maintained without adding to the difficulties of river traffic. The army engineers have maintained otherwise. At this stage of the controversy the chief engineers of the United States Army turned the case over to Naval Constructor D. W. Taylor, U. S. N.

That distinguished authority looked upon the problem largely as a development of the phenomena of reaction between the water and the shore. He has been recent on a reduced scale the flanking shores of the river with piers of suitable proportions. He sought to determine the sectional influence of a great river approaching and leaving her dock, both upon river traffic and upon the utmost value, and the problem of making records of all of the disturbing influences created by express steamers ranging in size up to a thousand feet in length, moving picture cameras were employed to catch every movement. Data have been obtained of the utmost value, and the problem of further extending the Chelsea docks has been thus disposed of. What would have continued to be a subject of discussion has been helpfully and suggestively settled at a very moderate cost.

Apart from the character, the manner in which this question has been brought to a focus and analyzed through the medium of the model basin has a native wide significance. Encroachments upon the tidal basins of many of our ports and the immediate dangers of commerce have caused impatience to be made, which, later on, may lead to troublesome conditions. Just as current velocities in some parts of New York harbor today are eighty-odd per cent greater than they were years ago. These changes add to the difficulty of river traffic and to the difficulty of all towing that must be done against the sweep of the tide. There, of course, of suitable proportions must be built for ocean liners as they grow, but they should be placed where they are least likely to disturb the regimen of the stream seriously. When these questions arise hereafter the model basin will be able to guide us more intelligently and will safeguard us against mistakes which may hamper harbor shipping in the years to come.

## Reliability Requirements and the Cost of Electric Power

MANY factors enter into the economics of electric power production. For the best economy it is, of course, desirable that the load be distributed as evenly as possible over the twenty-four hours of the day. The demand for electric power during the daylight hours, in plants whose main output is spent for lighting purposes, but there are other factors whose influence is more difficult to gauge in actual terms. That Dr. H. H. Woodruff points out that the cost of power depends among other things upon the requirement of reliability and continuity of service, a requirement which varies greatly in importance from case to case.

A breakdown, even of a few moments, in the electric power supply of a large city with a constant demand for lighting, running elevators and so forth, will not only cause great inconvenience and annoyance, but, as in a crowded theater for example, bring public and disaster in its train. This case is somewhat different as regards the demand for electric power in other and similar institutions. There a few minutes' breakdown is no doubt a cause of loss, but not comparable in its results with a failure extending over twenty-four hours, say. Then again, in certain cases a shut-down of even a fraction of an hour may mean great loss. If the current is cut off the factory it may mean that the chemical operations, even for a quarter of a minute, the whole charge may be lost, and the furnace itself may be destroyed.

There are many cases where the demand for electric power is so great that the loss of even a few moments may mean great loss. If the current is cut off the factory it may mean that the chemical operations, even for a quarter of a minute, the whole charge may be lost, and the furnace itself may be destroyed.

Women beheading the sardines and packing them in boxes

Sardines in racks mounted on carriage in the drying room

# The French Sardine Industry

By Jacques Boyer

WHEN you purchase a box of sardines, do you ever think how many hands it passed through before it reached yours? The little silvery fishes have been subjected to a long series of perils on the part of the fisherman who extracted them from the meshes of their nets, the women who cleaned them, cooked them and immersed them in a bath of oil, the tinsmiths who sealed the tins and a supplementary host of packers, carriers and wholesalers and retail dealers.

When the fishing boats arrive at their home port the sardines are taken to the factories where they are beheaded, cleaned, washed and then put into vats of brine, in which they remain from 15 to 45 minutes according to their size. On their removal from the brine they are laid on grids which in fine weather are carried to an open drying yard and in bad weather are placed in racks mounted on carriages which are placed in chambers traversed by a current of hot air.

When the sardines are dry the grids are taken to the kitchen where they are plunged into huge vats of boiling oil. This operation is watched by women who take care to remove the sardines before their flesh has been heated to excess.

After the sardines have cooled they are deprived of their tails and packed in tin boxes by women seated at long tables. The boxes are cleaned as whole halves and quarters. The quarter box contains eight sardines and is the most familiar size. Sometimes plastic-filled lemon or pickle and other condiments are put to the bottom of the box.

The filled boxes are placed on large trays and carried to the oiling room where the vats are quickly filled with oil flowing from a row of taps which the operator controls with one hand while with the other she brings each box in turn under a stream of oil.

The boxes are sealed either by soldering or by folding and pinching the edges. In the former case the soldering iron is continually heated by a blow pipe as it passes along the edge of the box which is clamped to a turn table. A single blow pipe furnishes the air blast for fifty or sixty flames tended by as many men. In the newer factories soldering has been replaced by the more rapid and more hygienic operation of folding and pinching which is performed by special machines. Effectively that the lid is hermetically joined to the box.

The sealed boxes are sterilized at a high temperature in autoclaves and are then rolled in sand to remove oil and other impurities from their exterior.

A curious and important fact in the biology of the sardine is the adduction with which these little fishes appear in great numbers and consequently valuable property is consequence of changes in

Filling the boxes with oil flowing from a row of taps

Workmen sealing sardine boxes by soldering.

seasonic conditions. According to M. Charles Rabot sardines appear in dense schools wherever they find the most favorable degree of temperature and salinity and disappear as soon as the water has been replaced by a current of different character. Unfortunately we know nothing of the physical conditions which the sardine seeks or of the movement of various strata of water along the coast. We do not know whether the sardine prefers warm or cool water, very salt or moderately salt water, nor do we know the temperature and salinity of the sea at different seasons, depths and distances from land.

In Brittany sardines are caught with a vertical net from 1000 to 1200 feet long and 20 to 40 feet deep which is supported by cork fastened to its upper border and is attached to the stern of the boat by a cord several yards long. As the boat moves slowly against the current the sardines are lured to the net by salted cod thrown on the water. The net is made of three or four fine that it is almost invisible and the meshes are of such dimensions that the sardines thrust their heads through them and are caught by the gills. Not raised after a few minutes trawling some times yields several thousand sardines.

This simple and time-honored device gives good results in the hands of the Breton fishermen but their rivals of the Gulf of Gascogne and the Atlantic coast of Spain and Portugal prefer the circular seine, which is made by completely surrounding a whole school of fish with a vertical net and then drawing the bottom of the net together by means of a draw stiling. The great bag thus formed is gradually contracted by hauling in and the imprisoned sardines are removed by means of landing nets.

The circular seine is very effective but its employment on the Breton coast is hardly practicable as was proved by experiment a few years ago. The French jockers nevertheless would like to have it adopted in order to increase the catch. Some experts recommended the Guinean net, a floating cage of netting open in front and on top which is towed behind the boat and entraps the sardines as it advances. When the catch is deemed sufficient both openings are closed by drawing cords. The top is then re-opened and the sardines are removed with landing nets.

The French fisherman however, fears that an increase in the catch will lower the price, and they are reluctant to adopt any improved device although the packers require cheap raw material in order to meet foreign competition, particularly that of Spain and Portugal, which annually throw about 1,800,000 cases of sardines upon the market. The problem, therefore, is a difficult one, and its satisfactory solution will require many years of combined effort from both sides, before the persistent tendency to sell from the demands of fishermen, tinsmiths and packers.

Right of way, showing joints after eighteen months wear

The 'Cleveland Flyer' stopped by the automatic system

### A Safety Automatic Train Stop

For the past year there has been under test on a five mile stretch of the Pennsylvania Railroad just outside of Pittsburgh, an automatic train stop system which possesses many points of considerable interest as pointed out in the article entitled "Successful Automatic Train Stop" in the *Scientific American* of January 14th last, chief among the requirements of the successful system are that it be entirely on the closed circuit principle that it be included in the circuit of the ordinary automatic block signals and that any fall out of electric or mechanical contact is a serious stop position. The present system conforms to all these requirements and in addition claims as further advantages that it requires no appliances on the roadways which might be damaged by rolling stock or that might be affected by sleet or snow, and requires no appliances on the engine which might be carried away by a projection from the roadway. Another important advantage it offers is that it can be made inoperative below certain speeds or it will release the brakes when the speed has been reduced to a certain value, making it unnecessary to come to a full stop before proceeding. Thus the engineer is allowed to use his discretion in passing a danger signal so long as he moves slowly enough to come to a dead stop. The instant the red danger presents itself to him it is well known that block signals are sometimes thrown out of order by lightning and any disarrangement of the system will result in the showing of danger signals. Under such conditions it is a decided advantage for the engineer to proceed even against the signals provided he maintains a cautious and safe pace. It is often considered desirable to have a record made of a stop in order to disclose a lapse on the part of the engineer in running past a danger signal. In the present system such a record may be made, not only of the full stop but in case there is no stop of the speed at which the train passed the signal. These adjuncts however, are not shown in the accompanying drawings of the system.

The apparatus carried by the train is mounted in the tender. The locomotive is insulated from the tracks and rear couple of the tender so that the circuit of the train apparatus is completed through the rails. As illustrated in Fig. 1 the locomotive is indicated as *L*, the tracks of the tender at *T* and the rear couple of the tender as *R*.

The apparatus comprises a low voltage battery *BH* adapted to energize a magnet valve *M* operating a brake valve *B*. In the circuit of the magnet valve is a relay valve *R* which is energized by current coming through its own contact so that if the circuit is once broken the relay must be re-energized through some other contact which is provided by cut off valve *C* or speedometer *S*. As a means of indication, whether the apparatus is under proper control the lamp *HL* is provided on the locomotive together with the key *K*. The

Instrument box carried by the tender

Fig 1—Diagram of engine apparatus in normal running condition

Fig 2—Diagram of engine apparatus when entering an occupied block

cut-off valve *C* then limits held open by a coil spring and when a cam follower is raised for air from the train line to the brake valve *B* and it is so connected for electric lamp *HL*. When the valve is fully closed it closes contact *C* in circuit with the relay *R*. The spring prevents the valve from falling in this position. When the valve is fully closed it breaks contact *C* for the lamp *HL* and cuts off the valve *B* from the train line.

The operation of the stop apparatus is accomplished as will be explained below. In the first position *F* a current *F* is made to flow through the system from the track which will normally the energy of the relay *R* permitting the contact *C* to be broken the circuit. If the valve *C* may be located in such place as to be broken in the track and making it impossible for the engine to enter the track until the train has come to a full stop. The speedometer *S* is provided with contacts that are closed at any speed desired so that a stop can be avoided if the speed is low provided the engineer closes the circuit of the speedometer by depressing the key *K*. He may also use this means of releasing the brake when the speed has been sufficiently reduced.

As the operation depends on the integrity of the insulation between the tender and its track it is necessary to provide a leakage device *L* in this insulation. This is accomplished by making the insulation in two sheets *II* with a steel plate *II* between them. The steel plate is made a part of the circuit of the engine relay and is so placed that any leakage through the insulation will pass the relay *R* and cause it to open. Since the rail between engine and tender is part of the engine circuit any breakage in *II* will at the same time will de-energize relay *R* and apply the brakes unless some other path be provided for the engine current.

At any location such as a block signal where it is desired to control the engine, insulated joints *I* and *I* (Fig. 3) are placed directly opposite in the track and track apparatus is provided to make this path if the track ahead is safe but to break the path or place it in an obstacle if the track is unsafe. The track apparatus at each station consists of a track relay *T* and insulated joints *I* and *I* as used at present automatic block signals a high resistance line relay *J* a detector relay *D* and a low voltage battery *B*. The relay *J* is connected in the same interval *II* used for operating the automatic stop and is controlled by track relays *T* at signal ahead. Two of the contacts of relay *J* serve as a relay switch controlling the relation of relays *D* and *T* the engine battery *B*. In order to be certain of the insulation of the insulated joints a master *M* detecting a break down is provided in the relay *J* which is normally de-energized and controls track relay *T* through a back contact but if the insulation of the joints should decrease current breaking across will energize relay *J* and thus de-energize relay *T* and relay *T* at the signal.

Fig 3—Diagram of the track circuit showing an occupied block

[illegible]

One of the accompanying photographs shows the 1 R R Cleveland River 11 night train at the automatic system. The man in the ground at the side of the tender has his hand on the valve key releasing the brakes after the engine has been automatically stopped. The relay and valve are all located in this box under the side of the tender.

## An International Congress on School Hygiene

ALL the leading institutions every State in the United States colleges and universities of note in this country and various other leading educational and scientific medical and hygienic institutions and organizations as well as such well known organizations will be represented at the fourth International Congress on School Hygiene in Buffalo August 25th to 30th are asking to a preliminary statement just issued by Dr. Thomas A. Storer of the College of the City of New York concerning the program of the congress.

[illegible]

It will the entertainment of delicious in any way be neglected. Buffalo have just subscribed \$40,000 to ward covering the expenses of the congress. The Buffalo citizens committee has planned for a series of social events including receptions and a grand ball a banquet in the park and excursion trips to the great industrial plants and to the scenic wonders of Niagara Falls.

The Congress is open to all persons interested in self defense who may join as regular active members. The payment of a \$5 fee Application for membership should be sent to Joe Thomas 4 Storey College 11 City New York New York City

### Death of Prof Slaby

**P**ROF. ADOLPH H. SEARS, of the Charloftonburg, Va. school, died on April 24 at the age of sixty-three. He was a pioneer in the field of wireless telegraphy. His first experiments were begun in 1897 on his return to Germany after having assisted Marconi with

his work in England. With the aid of Count Arco he developed the system known as the "Shirley-Arco," which later was combined with that of Hertz to form the "Telefunken" system. By using capacitors to store the electric energy he was able to accumulate the energy sufficient to establish wireless communication over a distance of twenty-one kilometers (12 miles). Hertz discovered that the ether is sensitive to differences of potential rather than to differences of potential difference, hence to produce the maximum effect it should be placed at the upper extremity of the antenna. As such a location would be inconvenient he modified his system by adding a horizontal wire of equal length to the vertical antenna. This modification was later placed in his ether at the end of the wire. Prof. Hertz also contributed much to the tuning of wireless telegraph apparatus using in the receiving set the autotuning coil with sliding contact so familiar to all wire telegraph operators which was invented by his associate, Count Arco.

### The Intractable Missouri-Mississippi System

In our front page illustration this week we have attempted to present in isolated form some statistics concerning the longest and in many other respects as well the greatest river system in the world. The Mississippi River is only about 2,900 miles in length and the Missouri River is well under 3,000 miles from its source in the Rockies to the point where it enters the Mississippi but its total length is the lower Mississippi to the Gulf of Mexico is 4,300 miles. How can we compare the two rivers? The only way is to compare them on a graphically in our front page illustration. You can consider also the Mississippi River equals in length the lower river in Asia.

The heart of the North American continent drains into the Missouri-Mississippi system. Two-fifths of the total area of the United States is comprised in this vast funnel-shaped river basin. No wonder this enormous body of water is dreaded when in flood and yet the very vastness of the basin it drains mitigates the danger for the chance of a combined flood from all the tributaries (if the river is remote) as pointed out in the report by Col. (Mell) Townsend, president of the Mississippi River Commission in the current SUPPLEMENT. The entire Missouri-Mississippi drainage area receives its water from the Gulf of Mexico and the Atlantic Ocean. The Gulf of Mexico sends its flood south to radiate in the northwest to the north or the northeast portion of this great drainage basin.

What a flood on the Mississippi means is shown graphically by comparing it with the Niagara River. The total discharge through the Niagara is estimated at 240,000 cubic feet per second. The average discharge of the Mississippi River is 610,000 cubic feet of water per second. In time of flood this is increased many fold. A record was established just over when in the vicinity of the mouth of the Red River the aggregate discharge of the river and the crevasse amounted to over 2,900,000 cubic feet per second. This equals more than eight Niagaras.

In our illustration we have represented this error as water flowing into a huge water tank. In order to hold a single annual discharge this barrel would have to have a capacity of 1,000,000,000 cubic feet, or would have to be 100 feet high, 12.5 feet wide and 100 feet long. It would be the height of the Woolworth Building. If the river entered into a lake of the size of New Jersey it would take it one foot in ten hours. The water would be so shallow that the amount of water flowing down the Mississippi would swamp it. It is how inadequate would any reservoir system be to keep the flood in check. As a matter of fact the present levee system is comparable to a reservoir system for which its confining walls the river is allowed to spread by the wind and the waves. The water is not at a normal depth and yet the waters are uncontrolled. At present the contents of the levees along the Mississippi River amount to 240,000,000 cubic yards and it would take 100 years to build a levee system of this kind adding in round figures the same number of cubic yards for each mile of river.

It is interesting to note that the Indiana River carries down in a single year enough sediment to build all of the present levees and practically all of the projected levees. Out of the Missouri River the Mississippi receives annually 400,000,000 cubic yards of sediment. The Mississippi River carries down annually 1,000,000,000 cubic yards of sediment, comparing it with the total excavation from the Panama Canal, which is estimated at about 210,000,000 cubic yards. In our illustration we show a dump car of a standard 12 cubic yard type, but enlarged proportionally until it is big enough to hold the entire contents of the Mississippi River. The Mississippi River is only a mile in length measured inside the body of the car. A large enough car would measure inside 6,100 feet in length and the body would measure over seven thousand feet in height. This we have illustrated by comparing it with the Panama Canal. The Panama Canal is only a car, would have where, larger than the car.

Shaner Building and only the Westport Building would reach up to Market St. His estimate of sediment is based on a report by Chas. Baker, who made observations at St. Charles, Mo., since February to October 1979. He showed that the average sedimentary discharge was 2.3 cubic feet per thousand cubic feet of water and this rose to a maximum of 16.7 cubic feet of sediment per thousand cubic feet of water. Four hundred thousand cubic yards per year means 12.7 cubic yards per second, that is over a railroad. In other words, if this sediment were carried by water it would fill a small swimming pool, 100 feet long, 10 feet wide and eight feet high the year round at the rate of seven miles per hour to deliver the material in the same volume as it is delivered by the Missouri.

## A New Method for Inducing Immunity Against Disease

In recent years there have been a number of successful experiments on a large scale with a view to inducing immunity against typhoid fever. It has been found that the method of injecting the preparation under the skin is in some cases compensated by disagreeable consequences. The use of the hypodermic injection is also by itself an additional danger point for in the hands of careless workers there is danger of blood poison. For these reasons many investigators have sought for another method of vaccination against typhoid fever. Prof. Jules Courmont of the University of Lyons has turned out a method

With the aid of his assistant Dr A Reichen, Dr Courmont first tried to introduce the vaccination material through the mouth of the animals with which he experimented—rabbits, goats and guinea pigs. The material used consisted of a quantity of the typhoid bacteria, which he had previously grown in a nutrient mixture, and then heating the mass to about 128 deg Fahr. The heat kills the bacteria but does not affect the poison. If a small quantity of this is introduced into the body the white corpuscles are induced to secrete the appropriate anti-toxin, and thus prepare the animal for the reception of the real toxin. But it was found that swallowing the toxin did not produce the desired results. This can be understood when we consider that the action of the poison on the stomach, the liver and the pancreas upon the toxin must either have destroyed it or modified it considerably before it could be absorbed into the blood through the walls of the intestines.

When it was demonstrated that this method was not efficacious Prof. Courmont conceived the idea of getting the material into the large intestine *directly*. For this purpose he used the same animals and gave each a number of irrigations; the results were entirely analogous to those obtained by the method of intratyphoid injection. To make sure that the method would apply to human beings the same experiments were repeated with a number of volunteers. Each received three enemas containing about three ounces of the killed typhoid culture at intervals of five days. As it was of course impossible to infect the young men with typhoid bacilli, the results of the experiments were of course negative. This was not the case when the irrigation was effective another method had to be resorted to. That was testing the behavior of the blood in relation to the specific microbes. Now in every case experimented upon it was found that the serum of the subjects blood killed cultures of typhoid bacilli. And in no case was there any unfavorable or untoward reaction. This method of treatment. This method, moreover, such for our future health.

Intestinal vaccination of the same kind was also tried on the experimental animals using the bacteria of blue pus instead of typhoid bacilli. The induced immunity was complete in every case.

### The Current Supplement

**T**HE most important official exposition of the problems of controlling the Mississippi flood is unquestionably a paper read before the recent National Drainage Congress in St. Louis by Col. C. McE. Townsend. I 'B A president of the Mississippi River Commission. This address is published in full in the current issue of *Engineering News-Record*. An article in this position is distributed by Rear Admiral Pearson, U. S. Navy. Col. Townsend's paper is a masterpiece of clear and logical presentation. Mr. Easlick contributes an article on the hardness of metals—A paper mill engine of new design is illustrated and described—Mr. G. B. Corliss' review of the development of the gas industry is concluded in this issue—A new automatic railway signaling system, derived by an Australian engineer in England, is described in detail. The paper contains the attention of many, since the days of Mr. Humphrey Davy—An article in this issue deals with electric lamps for mines. The fifth of Mr. S. S. Thomson's lectures on the structure of the atom is reported this week. The sixth and last of this important series, in which the great English physicist summarizes the state of knowledge of the atom, will appear in our next week's issue. This brilliant presentation will appear in our next week's issue.

# Floods and the Problems of River Regulation

By Charles Whiting Baker, Editor in Chief, Engineering News

Condition of caving bank at Caruthersville, Mo., at the time of beginning bank protection work.

**T**HE heavy rainstorm which swept across the country from Illinois to New England during the first week in March caused greater property damage than any other storm that has ever visited the United States. Public attention has been largely concentrated on the loss of life and property in such sorely stricken cities as Dayton and Columbus; but there were numbers of other smaller cities and towns in Ohio in the valleys of the Miami and Scioto and Muskingum rivers which suffered as severely. In fact all through southern Ohio and Indiana and the whole length of the Ohio valley every town and city located on a river bottom sustained heavy loss.

No widespread were the floods reaching eastward through northern Pennsylvania across the State of New York and even into New England, and westward and southward along the Mississippi River to the Gulf of Mexico, that nothing short of a census enumeration could determine approximately the damage suffered by probably a hundred thousand households and as many farmers in injuries to land.

Immediately following this widespread destruction there has arisen a public demand that something be done to guard against like destruction in the future. Bills are being introduced in Congress; prominent public officials are expressing opinions; the daily news papers are making diverse suggestions. It is important that the public should have an intelligent understanding of the subject.

And in the first place it may help us to form sound opinions if we understand that there are clear and

definite limitations as to what is possible of accomplishment. After all man is a puny creature compared with the mighty forces of Nature. He has indeed harnessed some of those forces, but he has been able to do this only by studying the laws which govern those forces and working in harmony with those laws. Long ago the work of the engineer was defined as "the harnessing of the great powers of Nature for the service of man." It is the engineer's business to know what can be and what cannot be done with those forces.

## The Cause of the Recent Floods.

The first thing an engineer does when he sets about the solution of a problem is to measure and weigh the quantities with which he has to work. As soon as the news of the recent floods came, engineers set to work to determine the rates of rainfall which caused them and the volume of flow in the flooded streams at various points. It is now known that the rainfall which caused these great floods was phenomenally heavy over a belt of country stretching as far north as Ohio along the low and flat divide between the rivers which flow north into Lake Erie and those which flow south into the Ohio River. At Marion, Ohio, 10.69 inches of rain fell in four days; at Bellefontaine, 11.16 inches; at Danversville, 30 miles east of Marion, 9.70 inches. This is as much rain as ordinarily falls in the space of three months in this section. It fell at a time moreover when the ground was already saturated and when there was very little evaporation so that almost the whole of this enormous amount of water flowed quickly off into the streams. It was the long

time that this steady downpour continued and not the amount of rain falling in a single hour which caused the damage. A summer thunderstorm often delivers a heavier precipitation over a small area for a few minutes or even an hour than fell in the same time in this Ohio storm. Such heavy thunderstorms over a small area often do excessive damage in the washing out of roads and culverts through the overflow of brooks and small streams. In the Ohio floods, however, hardly any of the small roadway culverts were washed out, but the bristling over the larger streams were carried away, proving that it was the long duration of the steady rainfall extending over a wide area, which was responsible for the great damage.

One of the most common and widespread fallacies with reference to floods is that they are more frequent now than in former years, and attain higher elevation, and that this is due to the clearing of the forests and the cultivation of the land, the draining of swamps, etc. This idea is so firmly rooted in the popular mind that it will probably surprise many to hear it called a fallacy especially as many distinguished men have given the theory prestige by their support.

It must be said nevertheless that in the opinion of the highest scientific authority the presence or absence of forests on a watershed has very little influence on floods in the streams which flow from it. It is another common fallacy that the presence of forests increases the amount of rainfall. There is no satisfactory evidence that this is the case at least under the climatic

Crevasse in the levee at Wilson, Arkansas, taken from the south end of the break.

Part of the broken end of the levee is shown in the foreground, the other end is beyond the trees. The water is pouring through this half-mile apart, with a ten-foot head and is flooding an area forty miles wide and one hundred miles long.

conditions that exist in the United States.

The idea that the climate is gradually changing stands on no more substantial basis, when one studies the weather records extending back not merely over the few years that the average person remembers but over a half century or a century. There is no reliable evidence that there has been any appreciable change in climate, so far back as authentic historic records extend.

There are, however, from causes not fully determined recurrent cycles of wet years and of dry years. Such a cycle of dry years, for example, during which hundreds of cities in all parts of the East suffered from insufficient water supply as a result of the drought, came in an and about two years ago. As according to the old adage, one or three follows another, we are apparently now beginning a cycle of wet years during which the average annual rainfall will be excessive instead of insufficient.

#### Forests and Floods.

It may be of interest to explain some of the reasons why the presence of forests upon a watershed has comparatively little effect upon floods during from it. That it does have some influence in equalizing the rate of runoff from a drainage area during periods of ordinary rainfall is well understood. But the match of dead leaves which covers the ground under forest trees has only a limited capacity for absorbing water. According to the depth of this match and the character of the underlying soil this match may be able to absorb like a sponge perhaps half an inch or even two inches of rainfall. After the point of saturation is reached however further soaking in is very slow, and if an additional heavy rainfall comes, it runs off very rapidly on the water surface formed by the rain which has previously fallen.

Some of those who have strongly advocated forest cultivation as a protection against floods have attempted to illustrate the behavior of the forest match in absorbing and equalizing rainfall by covering an inclined board with a sheet of blotting paper and showing how the blotting paper absorbs water sprinkled upon it, while water sprinkled on the bare board runs quickly off. But if this little experiment is carried further, it gives an excellent object lesson why we may do not and can not prevent floods. Continue the sprinkling of the blotting paper with water and after it has become saturated the water runs off as readily as it would from the smooth board without the blotting paper.

This is what happened in the recent Ohio storms. Day after day the rain steadily poured down upon ground already saturated from the winter snows and rains, and as soon as the ground surface was covered with water the additional rain flowed rapidly off on the surface of the water underneath. When it is remembered that the total depth of the rain which fell in this two-day storm was nearly a foot at some points, it can readily be understood why there was a rapid and enormous discharge into the Ohio River and why this discharge would have taken place and the great floods have resulted just the same, even if the whole State of Ohio had been covered with the primeval forests.

Another idea there are many thousands of feet beneath the surface of the earth were covered with forests. As explained above, the forest match has a limited capacity for absorbing water.

The lower Mississippi, inundated by floods from the 20,000,000 acres protected from inundation by levees. The lands protected by the levees are wonderfully fertile, and many plantations are valued at \$100 to \$500 per acre. Such as the levee in the great flood of 1913 inundated only a small part of this area.

flood in this river on March 27th to 28th was enormous and caused great damage at Cairo and Albany, yet the height which the flood attained and the volume of water flowing in the river were after all less than in the flood which occurred in September, 1859. Now the Hudson River above its junction with the Mohawk receives nearly all of its water from the southern part of the Adirondack region. In 1857 nearly the whole of this region was covered with primeval forest. Better proof that a forest cover upon a watershed cannot prevent great floods in the streams flowing from it could scarcely be given.

Old records show also that in 1842 there was a flood in the Ohio River at Pittsburgh which was five feet higher than the flood of last month. In 1842, however, a very large part of the water sheds of the Allegheny and Monongahela which meet in Pittsburgh to form the Ohio was covered with dense forests.

As to the prevalent idea that the cultivation of the prairie and the draining of the swamps has increased the floods in the Mississippi River it is of interest to note that the greatest flood height on record in the Mississippi River at St. Louis occurred in 1844 and the next highest in 1783. At both these dates the entire territory drained by the upper Mississippi and the Missouri rivers was in its natural condition. The trifling amount of settlement and cultivation at that early period could have had no influence in the rate of runoff.

Similar instances without number could be multiplied all going to prove that the volume of flood flow in our streams and rivers has not been materially altered by any changes which man has brought about. The floods which have wrought such destruction this year, therefore, are nothing but what has occurred before and will doubtless occur again and there is no evidence to show that they are likely to come with any more frequency in the future than in the past.

#### How Far Man is Responsible

While there is thus no evidence to show that the changes brought about by man upon our continent at least have affected the rate of rainfall or the runoff from drainage areas so as to have any influence on floods, there are certain changes for which man is responsible which have affected the ability of the river channels to carry these floods.

When rivers pass through cities their channels have often been narrowed by gradual filling in of the banks on either side. Individual property owners along the shore have a strong temptation to do this because of the additional area of land which thus occurs. Bridge piers and dams in a stream also operate to reduce the channel capacity. Most serious of all, however, are the levees which have often been placed across the flood plains of rivers.

An ancient knows most streams and rivers flow in a comparatively narrow channel through a broad valley and are bordered on either side by broad stretches of meadow or bottom land. These bottom lands are termed by geologists the river's flood plain. They have gradually been built up through long ages past by the deposit of sediment from the river when in high flood.

To man with his short span of years on the earth, it seems high enough to cover these bottom lands with crops at long intervals

part and it seems incredible that these broad plains with their deposits of sand and gravel and all many feet in depth have all been brought down and deposited by the stream during periods of high flood. The deposits themselves however tell a story whose truth it is impossible to controvert. These broad level bottom lands along every stream are proof in themselves that the river has in past ages frequently covered these plains and while it is true that many such bottom lands probably gained much of their deposit during the glacial epoch following the glacial period when enormous runoffs and erosion occurred, it is also true that many of these flood plains are the results of deposits made within historic times.

In other words, every river has two channels. The first its ordinary channel, carries the whole flow of the stream at all ordinary stages the second or flood channel is inundated by floods which may occur on some streams once in a decade, in others once in a half century or century or perhaps at even longer intervals.

The bottom lands, or flood plains along a river are invariably fertile and produce river lands they usually support a dense population. Again nearly all cities and towns are built on rivers of greater or less size. They were originally located there because of the advantages of transportation or water power or water supply and as they have grown they have spread over the flood plain of the river and are subject to inundation, therefore when once in a century or oftener, a record-breaking flood in the river occurs. The height of such floods is increased, as is also the velocity of the current by the obstruction to the water's flow by the encroachments on the channel and the buildings and the obstructions built on the river's flood plain.

Still another way in which man has defiled the capacity of rivers to carry floods is when by cultivation, forest removal, road construction, etc., he has caused earth and sediment to be carried into the streams, which has tended to fill up the channels.

The amount of this injury to river channels, however, has been probably overestimated by many. The large rivers have suffered little deterioration of their channels so far as measurements can determine. There are, however, certain sections where the work of man has undoubtedly injured the rivers. Most notable are the rivers of California which years ago received the debris from his drastic mining.

So far as the rivers whose floods caused such destruction in Dayton and Columbus are concerned it is doubtful if any material shoaling of their channels had occurred as the result of sediment carried into the streams. The volume of the flood water was so vast that had the ordinary river channel been as much as five feet deeper or five feet shallower, the flood destruction would have been little affected either way.

To recapitulate then, the recent floods were caused by an extraordinarily heavy rainfall, and nothing that man has done in removal of the forests, cultivation of the ground or drainages of swamps had anything to do with it. Such floods have come before and will come again but at long intervals. To such occasional devastation every city built upon a river's flood plain is liable, but since floods are not increasing in frequency or in height the danger is no greater to-day than it always has been.

It must be remembered, however, that the flood plains of a river may be at various elevations. Some parts may be overflowed by such high water as comes every year or even several times a year some parts are reached only by such floods as come on the average at intervals of five or ten years, other places are inundated only by such extraordinary floods as may occur at intervals of a century.

#### How Floods May be Controlled.

There are two general methods by

A lake steamer was broken from its moorings by the force of the current and was carried against the pier of a swing bridge across the river. It knocked the bridge of the pier into the river causing a loss of a quarter of a million dollars.

Wreck of a swing bridge over the Cuyahoga River at Cleveland, Ohio.

This net floating over the section of bank to be protected, is being held in place by wire nails while stone is unloaded from the barge and placed evenly upon it in the crib provided. It will sink uniformly in place and will extend from the water surface toward the bottom of the river like a great rock curtain. These revetments, as they are called, cost from \$20 to \$30 a running foot. If the caving banks could all be treated in this way the channel would remain permanent.

Example of bank revetment work.

which the flood waters of a river may be controlled and prevented from spreading over its flood plains. The first is to build embankments or levees along the river banks so as to confine the waters within the ordinary channel. The second is to build reservoirs upon the tributary streams which form a river and store up in them the flood waters, to be gradually discharged later to supplement the river's low-water flow. The relative merits of these two methods are just now the subject of active public discussion.

The reservoir system is, upon a superficial observation, very attractive. The proposition to store the water which would otherwise rush down the valley creating waste and destruction along its entire path to the sea, and to use this stored water to develop power, to irrigate lands in time of drought or to increase the low water flow of the rivers for the aid of irrigation—all this seems to us from to be an ideal plan.

Moreover, its advocates can point to instances where river regulation by these methods is being actually accomplished. The Croton River for example, which furnishes New York city's present water supply, has had so many reservoirs built upon its watershed, that unless a very heavy rainstorm should come at a time when the reservoirs were all filled, the entire flow resulting would be caught and stored for the city's use. Boston stores the Nashua River's flow in a similar way. At Panama, the floods in the Chagres River are now stored in the great Gatun Lake, which will become as it reaches its final depth and area the largest artificial body of water in the world. Still again in the arid West, great irrigation works are dependent on the storage of flood waters in huge reservoirs.

#### The Reservoir System.

It is to be especially noted, however, that all these reservoir systems are on rivers of small size. Further, their construction has involved a huge expenditure of money. The city of New York has spent millions of dollars on a single one of its reservoirs in the Croton watershed. The Gatun dam is an essential part of the \$400,000,000 Panama Canal works. Such expenditures can be afforded because of the high value of water used for a city's water supply, or even for irrigation.

When we apply the cost of reservoir construction per million gallons of water stored to the huge volumes of water required to be stored if we are to take care of the flood waters of rivers draining thousands of square miles, the magnitude of the sum required becomes appalling.

During the recent floods at Columbus, Ohio, the volume of the Scioto River's flow where it passed over a great weir dam just north of the city was very accurately determined. In round numbers, at the crest of the flood, the river passing through the city had a volume of 130,000 cubic feet per second. A river in flood with a swift current may have an average velocity of four miles an hour or approximately six feet per second. Such a river with an average depth of 10 feet would have to be 1,500 feet in width to discharge a volume of 130,000 cubic feet per second.

If the reader will picture to himself some of the natural lakes or artificial reservoirs with which he is familiar and imagine such a great river flood, more than a quarter of a mile in width, sweeping down into it, he can realize how brief a time it would take for such a flood to fill it.

In the city of Columbus, the river covered the entire width of its flood plain, a breadth of over two miles. There are very few artificial reservoirs anywhere which have as great a width as this. When one witnesses such a river as the Scioto, which at lowest water can hardly float a row-boat, transformed into a stream four half a mile to several miles in width, it can be appreciated what vast reservoirs would be required to store any considerable part of the flood flow.

Where could such vast reservoirs be

located? The river which flows past Columbus drains some of the most fertile and densely populated farming regions of Ohio. The dwellers in these upper valleys would resist to the utmost the appropriation of their lands for reservoir bottom.

Moreover, storage reservoirs can be economically built only where a deep narrow gorge occurs on a river below a broad level valley. Such reservoirs exist in northern Ohio are lacking. Still further, in order to have prevented the recent floods by storing the flood waters, reservoirs of huge capacity would have been necessary on the Walsh, White and Whitewater rivers in Indiana, on the Maumee, Cuyahoga, Miami and Muskegon in Ohio, on the Allegheny and Beaver in western Pennsylvania, on the Genesee, Mohawk and Hudson in New York, and on a multitude of smaller streams besides. And the next great flood bringing rainfall may come on an entirely different territory, where these reservoirs would be of no use.

At the recent National Drainage Congress in St. Louis, Col. C. M. Townsland, U. S. A., president of the Mississippi River Commission, presented a graphic statement showing how the floods on the lower Ohio and Mississippi rivers are due to rainfall upon their lower tributaries rather than from the distant headwaters in the mountains, where the advocates of reservoir control propose to store the water.

In the recent Ohio flood region, the city of Cairo, at the junction of the Ohio and Mississippi, was so threatened that women and children were sent away and the city was more than half depopulated. The crest of this flood reached a greater height at Cairo than any ever before recorded. Suppose there had been a huge storage reservoir available, not merely on the headwaters of the Allegheny and Monongahela, but at the city of Pittsburgh itself. Suppose there had been another such huge reservoir at St. Paul, Minn., capable of taking all the flow of the upper Mississippi. Suppose another had existed at St. Joseph, Mo., sufficient for the whole flow of the Missouri.

The length of time required for a flood wave to pass downstream from these several points to Cairo is known. Suppose, therefore, that in order to protect Cairo and the lower Mississippi Valley from the recent flood the gates of these reservoirs had all been closed, so that not a drop of water would have been allowed to flow past Pittsburgh or St. Paul or St. Joseph until the flood wave be too late to meet the flood from the lower Ohio tributaries and add to the volume at Cairo. Col. Townsland then shows that the recent flood flow of 2,000,000 cubic feet per second, which the river at Cairo attained at its record height, would have been diminished by only 35,000 cubic feet per second by such reservoirs, or less than two per cent of its total volume.

Limitations of space forbid a further estimation of the inherent difficulties which make control of the floods of great rivers by artificial reservoirs as difficult and impossible in practical execution as it is attractive when viewed superficially.

#### Morris of a Good Levee System.

Attention may be turned, therefore to the levee system of river control, which has been adopted by engineers the world over to protect the flood plains along a river's course from inundation. In the United States the best known example of river control by levees is the lower Mississippi River. This river is now bordered on either side by levees having a total length of some 1,600 miles, containing nearly 200,000,000 cubic feet of earth. These levees protect from inundation some sixteen million acres of lands as fertile as any on the globe. In its present condition the levee system is sufficient to confine all ordinary floods, and in the years from 1867 to 1912 the floods of the Mississippi were held between the levees except for a few small breaks in 1903. The extraordinary flood of 1912 and the one which is now passing down the river have each exceeded all previous records in height and will doubtless result, as they should result, in large expenditures to raise and strengthen the levees and to erect carrying locks along the river.

Along a few weak points in the levees failed in last year's flood and in the year before. The levee at New Orleans is one of the best. But the levees have been built up to the height and the width and the strength that nature has made it so admirable. The levee at New Orleans is the best system along

the river were willing to tax themselves for To raise and strengthen the levees so that they would be safe against floods much higher even than those of the present year would cost less than \$1 per acre of land protected, and as much of this land is worth \$100 per acre or more, it will be seen that such strengthening of the levees is easily practicable financially at the expense of the property protected.

It is doubtless too much to expect that the general public, deceived as it is apt to be by the pseudo-scientific of the newspapers, will form correct opinions on such matters as river regulation and flood control for a long time to come. It may be hoped, however, that the public will learn to rely in such matters on the opinions of expert engineers. Already the Secretary of

The prehistoric mounds of mound mounds are sometimes thirty feet high and one hundred feet in diameter.

#### Live stock which has taken refuge on a prehistoric mound.

War has convulsed a board of engineers efforts to report upon the recent floods, and there may eventually result a Federal engineering organization which will deal with matters of river regulation for the country at large, at least where interstate rivers are concerned.

It is not for a moment to be expected that such an engineering organization could perform such imposed duties as the general prevention of floods, but it could have jurisdiction over river channels to prevent their improper obstruction and narrowing. It could advise a city, or a State as to what protection in the way of levees or land elevation by filling was requisite for reasonable protection against floods and it could control the construction of levees for water power, irrigation, water supply, etc. so that State boundaries should not stand in the way of providing for the great

#### Antiseptic Properties of Tobacco

LIKE many other narcotic poisons, nicotine has certain properties which give it definite value in medicine when employed in the proper way and by competent agents.

Thus poultices of fresh tobacco leaves have long been employed to give relief to cases of gout, neuralgia, and rheumatic pains. A concentrated solution of the fresh leaves is said to be useful for rheumatic affections. Tobacco is also employed as a remedy for skin diseases of cattle, and is commonly used to destroy parasites in vineyards and orchards. Recent inventors showing its high value as an antiseptic agent are commencing to use it for this purpose. (From from which we quote. The researchers of Tassinari and Molich have now demonstrated the actual antiseptic value of tobacco with regard to both to vertebrates and to invertebrate creatures.

Tobacco smoke serves to retard or arrest the development of certain pathogenic bacteria. Anonin obtained from tobacco, when mixed with water, is said to be a powerful antiseptic. It is also used in the form of a disinfectant. It is also used in the form of a disinfectant. It is also used in the form of a disinfectant.

This bactericidal and antiseptic action has not yet been fully elucidated, but the Italian physiologist (Cavallaro has proved (in a *Stomatologia*, Milan 1910) that smoking not only increases the flow of saliva, which probably explains the antiseptic action of smokers after eating until they are able to inhale in pipe or cigar) but also sterilizes it. He also declares that tobacco is never the cause of oral inflammation and the epithelial tissues of the mouth, though it may be the determining agent which makes such cases, which are many and complex in character active.

When these statements of Cavallaro were published they aroused much controversy, being bitterly attacked by the numerous writers who were supported by a series of clinical experiments. He concludes, however, have just been brilliantly confirmed by the work of Prof. Wenke of the Imperial Institute of Berlin, who made many experiments during the recent cholera epidemic.

Prof. Wenke was struck by the fact that the recent cholera epidemic of that city were not attacked by the disease even when living in surroundings similar or identical with those of the victims.

The medical investigation he found that the water employed in one of these factories contained considerable numbers of septic vibrios, yet none of these was found alive on the finished cigars. This led him to definite experiments. Some of the tobacco leaves were moistened with water containing the bacilli of cholera in the number of 1,000,000,000 to the cubic centimeter. At the end of 24 hours these were all found to be dead.

A second experiment was made with water containing cholera germs, placed on a glass plate and exposed for 5 minutes to tobacco smoke, which completely sterilized it.

Finally it was found that a fumigation of from 25 to 30 seconds with tobacco smoke sufficed to disinfect the dress of patients seriously affected by attacks of cholera.

It is believed that other harmful microbes will be shown by future experiments to be similarly destroyed.

#### A Silicious Wood Preservative

TECHNICAL journals have recently mentioned the impregnation of timbers with metasilicic acid and naphthalene. But the new West process has been described in this method. Diatomaceous earth, a silicious material, is ground so fine that ninety-two per cent passes a two-hundred mesh screen. This is mixed with the melted paraffin and the naphthalene and timbers immersed in the mixture for four hours. As compared with the twelve to twenty four hours required in crocinating, this is noteworthy. Furthermore, it is an open vat process. The wood is permeated to the center and resists the attack of marine borers and decay twelfth gaining in resistance. No hot water is used, nor does the wood become waterlogged. Hardwood like white oak which resists other treatment yield to this preservative. The expense is small, for the mixture costs only three cents per pound and less than two pounds of solution are required for each cubic foot of timber.

This is the levee line along the St. Francis River; it extends from Point Pleasant, Missouri, to Helena, Arkansas—a distance of two hundred miles. When a break like this occurs, three million acres are flooded if the entire basin fills up. This view is taken from the inside and shows the height of the earthen wall that is holding back from ten to twelve feet of water at the river side.

A pen built around a leak on the inside of the levee with sacks of earth.

benefit to the greatest number of people with the minimum of expense.

#### The Death of Carl Hagenbeck

ON April 16th, Carl Hagenbeck, the well known dealer and trainer of wild animals, died at the age of sixty-five. He supplied many of the zoological gardens of the world as well as many circuses with their collections of wild beasts. His famous private zoological garden in Hamburg has been described in these columns. Our readers will recollect that instead of confining animals in cages, he allowed them to roam at will in the open air, preventing their escape by means of ditches filled with water.

# The Hydro-Aeroplane Meet at Monaco

## Description of the Machines and the Tests Which They Had to Undergo

WE illustrate on this page some of the score of more hydro-aeroplanes and flying boats which took part in the second annual meet at Monaco. While nearly two score machines were to compete in this meet, but sixteen qualified by being exhibited prior to the meet on April 3rd. These included three hyper-duskin monoplanes, two Nieuport monoplanes, two Borel flying boats, two Astra biplanes, two Breguet biplanes, one d'Ardie biplane, one Morane monoplane and one de Moravay monoplane with foldable wings. These machines were arranged in four rows just inside the harbor line as shown in our illustration. Three or four of them made their first flight at this meet on the 4th ultimo. In the evening, however, and throughout the whole of the next day a heavy gale prevented any flying, and the machines were obliged to be sheltered with the exception of two—Prevost's biplane and the de Moravay foldable wing monoplane, both of which rode out the storm at their moorings. The latter machine was illustrated in the *Scientific American* as something over a year ago. It is a novel machine, the wings of which are arranged to pivot around an axis near their inner end and to fold back alongside of the body of the monoplane.

No flying of any account occurred again until Sunday, April 6th, upon which day preliminary flights were begun, thanks to the Maurice Farman and Labouret on the Astra biplane, together with Weymann and Espérandieu on Nieuport monoplanes, accomplished the starting, towing, and navigability tests. Gilbert on a Morane monoplane carried out the first and Prevost, on the Breguet biplane, the last of these three tests.

The following day Labouret's Astra biplane landed on one wing and capsize with serious result. The three hyperduskin monoplanes were also put out of commission, seemingly from striking the water too sharply. Fortunately, this did not happen until after Prevost had succeeded in completing the three tests above mentioned, and also the altitude and volplane test as well as being the only one to accomplish the two latter tests up to that time. The two Borel monoplanes completed the starting, towing, and navigability

tests while Garbat and Bregat finished. The various tests to be made were divided under six heads, and were as follows: (1) The starting test. After the machine had been brought to a standstill on the water, the motor was stopped and the pilot obliged to start the motor with the sole assistance of the passenger and without touching the propeller, and then to cover a distance of 100 meters between two lines of buoys.

(2) Altitude Test.—The machine must rise from the water to a height of at least 300 meters and return to the water in less than thirty minutes.

(3) Volplane Test.—The machine must rise from the water to the height of at least 100 meters, shut off the power, and glide to the surface.

(4) Handling Test.—The machine must be brought to the crane and fastened to same so that it could be raised and lowered without damaging it.

(5) Towing Test.—The machine must be towed by a rowboat or motor boat over the course used in the first test.

(6) Navigability Test.—The aeroplane must circle a course of 6½ kilometers under its own power without leaving the surface of the water. All the above tests except No. 4 took place outside of the harbor in open water. As the result of this, Fischer had his Henry Farman biplane pretty well smashed by a downfall into the water when he was flying in a terrific wind of forty miles an hour velocity early in the meet while Louis Garbat was drowned as a result of his machine diving below the surface when he was skimming close to the waves on April 6th. The accident is said to have been caused by the tip of one wing striking a wave, whereupon the aeroplane dove beneath the surface, causing the aviator to be drowned before he could free himself. This is the most remarkable hydro-aeroplane fatality which has occurred, and it was probably the result of flying too close to the water when there was a heavy sea.

The race for the Jacques Schneider International Aviation Cup for Hydro-aeroplanes occurred on April 17th and was won by Maurice Prevost on his 100 horse-power three-engine hyperduskin monoplane.

The race was over a course of 150 nautical miles, and besides the cup there was a cash prize of \$5,000. The photograph of his machine with the completely enclosed motor, having a conical rounded shield, is reproduced herewith. The race was an international affair, with Charles T. Weymann representing the United States with a Nieuport monoplane, Garros with a Morane monoplane and Espérandieu with another Nieuport represented France.

Early in the race Garros experienced engine trouble and had to alight upon the water and be towed back for repairs. After his second start, he again had engine trouble and was again towed into port, but as Espérandieu had abandoned the race, Garros took heart and started for a third time. Prevost, of course, reached the finishing line first, but he was skimming along on the surface of the water and was not flying. It was decided that he must cross the line once more, this time in full flight, in order to win. Weymann, who was pressing him close, was obliged to descend on account of motor trouble. He had failed to carry enough lubricating oil to finish the race. Also, not knowing that Prevost was obliged to cross the line again, he quit without attempting to finish. Garros was still flying when Prevost made his second crossing of the finishing line, but he immediately landed and withdrew when he saw the race had been won. The race was down under ideal weather conditions, but it was not at all exciting on account of the numerous motor failures.

As for the machines which participated in the Monaco meet this year, most of them were equipped with double floats. There were several examples, however, of single float equipment, such as that shown on the Breguet biplane fitted with a 200 horse-power, horizontal, circular Salmon motor illustrated in one of our pictures. Whether there is a single or double float under the front of the machine proper, there is always a small float under the tail to carry the weight in the rear. In the case of the Henry Farman biplane, two cylindrical floats were used—one on each side at the rear. The single floats are generally notched and are in reality single step hydroplanes, but when double

Rear view of Borel flying boat.

Note peculiar floats on ends of triangular wings forming lower plane of this biplane. Also elevator hanging down over vertical rudder.

Fischer's Henry Farman biplane at rest.

Note the sharp angle at which the machine is placed, also cylindrical floats at rear.

Breguet biplane with 200 horse-power Salmon motor.

In addition to the single main float, there are two smaller boat-shaped floats, one on either side.

Astra biplane, showing motor of the Charles T. Weymann, with propeller mounted on a vertical shaft.

Many of these are generally flat on the bottom after the manner of the Currier. Most of the foats are flat, more-or-less affairs, though some of them are more or less pointed and rounded off on top. As a rule, they are made of wood or of veneer, but when cylindrical foats are used, these of course are of metal. The foats used on the Monoco monoplane have little wings on each side for the purpose of stopping the foat from diving and drawing the machine under in a sea.

There were a number of flying boats on the order of those originated by Curtiss and Doucet-Lerques. One of these, the Bregat, we illustrate. This is in reality a monoplane, although it is in tendency to be a biplane and is really in the biplane class on account of the small fus, one on each side of the boat, that support the lower plane. These fus each have rather clumsy, rectangular, fish-shaped foats beneath their outer tips. The men occupy a position side by side in the front part of the body of the machine, which forces the boat, while the Gnome motor is placed above at the rear edge in a notch in the plane.

Curtiss is at the present time building a new form of flying boat for Mr. Harold McCormick of Chicago, in which the motor is placed forward of the two planes and about half way between them, while the boat is beneath the planes and the passengers occupy a position about on a line with the rear edge of the planes, but beneath them. This seems an excellent design as in case of a plane into the water, the motor would be unable to fall upon the occupants or in any way trouble them. The placing of the motor in the boat well forward would also seem to be a good location.

The Monaco meet has demonstrated the safety of the hydro-aeroplane and the usefulness of the flying boat, and without doubt such craft will increase and multiply very largely both here and abroad during the coming summer.

### Artificial Limbs: Ancient and Modern

By Arthur H. J. Keane

MAN is undoubtedly the superior of the Autom in many ways, but it cannot be concealed that, in some things, animals have considerable advantages which we may well regard with envious eyes. Take the crab and the lobster (to mention but a couple by way of example) for instance, should one of these creatures lose a limb as the result of accident, attack or strife, kindly nature at once sets to work to supply the individual with a fresh member quite as good if not better than its predecessor.

Man, on the contrary, has to rely upon his wits to make good those losses which result from his wars, street accidents, railway collisions and other *de re malis* chances to which he is exposed at any minute. Many of the marvelous artificial limbs now obtainable are regarded as essential products of modern times, but, as a matter of fact, appliances of this kind are by no means modern. In the museum of the Royal College of Surgeons, Lincoln's Inn Fields, London, there is an artificial leg, made about 600 B. C. of bronze, wood and iron. Again, who has not heard of the famous "Iron Hand" made in Nuremberg, Germany, in 1504, for the German knight, Otto von Blichenstein? Among the old-time Indians, ears, noses and lips of plaster were quite common, one of their ordinary punishments being to cut off these useful parts of the human anatomy. Croquet and Roman gladiators who had lost a leg or an arm in the wars used to replace them by very capable substitutes, and Plinius speaks of a Roman soldier who (about 100 years B. C.) was famous for his wooden hand with which he was able to fight as an able swordsmen. In 1604 the Duke of Brinsford had to use an artificial hand.

Artificial limbs with movable joints were also largely used by the famous Amleth (Hamlet) in 1600, the celebrated Frenchman, the Father of the "Mephistopheles," the young man, Henry II., and also Francis II., Charles IX., and Henry III. The celebrated King of Sweden, who was the subject of the famous Swedish story, probably had some of the most perfect artificial limbs made in his time.

Artificial arms and hands. About the mid of the sixteenth century Falcioulli a Florentine surgeon, mentioned artificial arms of gold, silver and crystal painted in different colors. He also describes gold and silver arms which were either tied to the hand with strings, or else sewn on the skin of the scalp by the aid of gold and silver wire. Silver noses are spoken of also as having been in use for a long time.

Artificial arms, legs and hands are fairly well known and need but little description. Of the more concealed members we may mention artificial feet which vary considerably in construction, material and price. After

slightly. The simplest form of artificial foot is a peg at the end of a "bucket" which holds the stump. The center of the artificial ankle is often on the ball and ankle joint principle. The artificial foot is sometimes extended by means of cutaneous strings fastened at the back of the knee, with flexible bands passing down over the upper surface of the foot. In some operations (amputation below the knee) pressure can be borne on the extremity of the stump and the foot can be made to suit the purpose and occupation of the patient in amputations above the knee the weight can be borne either on the extremity or by a leather shoul. The simplest form of artificial hand is a leather shoul held to the arm stump, and so fitted that a knife fork or spoon can be screwed into it. Other hands open and close by hydraulic pressure the leather hand is of wood with a movable thumb. Prices of artificial limbs vary greatly for instance an ordinary hand leg on which the cripple leans with the stump pointing to the rear can be had for about fifteen shillings, while a jointed mechanical leg may run up to as much as fifty guineas.

One of the greatest triumphs ever reported in this curious industry however is undoubtedly the one incident here worn by a man whom Dr. Faill (a French doctor) exhibited recently to the members of the French Medical Academy. Owing to the accidental discharge of a fowling piece the whole lower portion of this man's leg was destroyed and a portion of the tibia seriously damaged but by a marvelous piece of mechanism the patient has had his appearance restored to him. The mechanism consists of four parts. In the first place a silver grooved cone in which the lower row of artificial teeth are fixed attached to the tibia contain the upper teeth there is also a second part of industrial rubber and gum to hold the upper front teeth, which is trailing in two small lower lips, shaped as in a hook into the nostrils. The third part consists of the chin and lower lip which are made of special soft rubber painted in flesh that in a most deceptive manner. The chin is also covered by a false beard. At the back of the portion there are several small screws which pass through holes in the teeth holding them thus join the chin and lip to the artificial upper jaw and palate. The fourth and last piece is the upper lip and nose, also made of flesh tinted soft rubber and covered with a false moustache. Thanks to this artificial contrivance the man is able to speak and chew his food, walk at a short distance it is impossible to discern that his face is not natural. The different parts have to be renewed every day, and well washed with water and soap.

It is to be hoped now that alchemists in the air some good points will discover an artificial skull capable of withstanding bombs and shot dropped from the clouds.

### A New Solvent for Compressed Acetylene

THE tank of compressed acetylene, carried by autos for their lamps is safe enough because the gas is dissolved under pressure. In acetone. An attempt to compress the pure gas would result in an explosion, immediate or delayed but violent. The search for a substitute for acetone has resulted in the recommendation that acetaldehyde be used. It is cheap and will become cheaper as it is made by the partial oxidation of acetylene alcohol but it possesses other advantages.

In industrial practice fifty ounces of acetone dissolves, as a rule, thirty seven ounces of acetylene at 70 deg. Fahr. and two hundred and fifty pounds pressure, while eighty two ounces of acetaldehyde have dissolved forty eight ounces of acetylene at 70 deg. Fahr. and two hundred and sixty pounds. It is evident that acetaldehyde is the better solvent. It burns with a heat nearly as great as that of acetylene itself, and in metal cutting or welding by the oxy-acetylene blow pipe it cools the flame very little. With acetone there is only an hour's warning before the gas gives out but acetaldehyde develops a round, black spot in the flame five or six hours before exhaustion of the gas.

Note the most foats at ends of lower plane. The one beneath the tail is hidden, but the struts supporting it are visible.

Front of Prevost's Deperdussin with 160 horse-power Gnome.

The three foats are clearly seen. Note the hemispherical wind shield in motor in foreground. The body has a strutsless form.

General view of the hydro-aeroplane "port" at Monaco.

what is known as a Hay's or a Choquet's operation (loosening the heel and a part of the sole of the foot), the main idea is to make a preventable appearance with a modified foot. In cases of higher amputation where an artificial ankle-joint is needed, it may take the form of a transverse rod working in a socket, or of two "rule joints," one on either side of the stump, the lateral yielding of a foot is sometimes limited by side supports which yield to lateral pressure. One of the best modifications for the real foot is a curved sole (Parker foot), where the movement has a natural appearance. Though the substitute itself is somewhat un-

# The Heavens in May

## Motions of the So-called "Fixed" Stars

By Henry Norris Russell, Ph.D.

As we look out upon the constellations, which after a brief acquaintance become so familiar to us, we may be from year to year impressed with the utter absence of change in their outline. More exact studies of the motions of the stars which compose them only deepen this impression, for we learn that no changes which would be at all conspicuous to the unaided eye have taken place in the appearance of any one of the stars from its rise in the last three thousand years. But when we scrutinize our minds to a different timescale measuring the intervals between our languid observations, not in years, or even centuries, but in hundreds of thousands of years, we come upon quite a different state of things.

It may seem bold to attempt to forecast at all what the heavens will look like a hundred thousand years from our era, but for the brighter stars their apparent motions have been so carefully observed that, if they continued to move over the heavens at the same apparent rate, their positions even at that very remote epoch, could be forecast accurately enough to make a very fair star map for naked-eye purposes (though many stars might be a degree or so out of place on it).

But for such long intervals of time we cannot safely assume that the apparent motions of the stars in the sky will be uniform. The stars are actually moving in straight lines at uniform speed. But from this very fact it is evident that any star must seem to us to move fastest in the sky when it is nearest us, and slowest when it is in other portions of its track (both because it is then further away and because its motion then makes an oblique angle with our line of sight instead of a right angle).

If a star is coming nearer to our system it should therefore appear to move over the celestial sphere with gradually increasing speed, and the opposite will be true if it is receding from us. This change in speed will be very slow, and will not become perceptible even to the most refined observations, until the star has moved over ten or fifteen million of years. So far it has been detected by direct observation for only two stars of very large proper motion—Drumheller, 1930, and 61 Cygni. For both of these Prof. Ross finds that the apparent motion is gradually increasing in rapidity, from which it follows that these stars must be coming nearer our system, a result fully confirmed by direct spectroscopic observations.

For many other stars, however, we may predict with confidence that similar changes in their proper motions will occur. If we know the parallax  $\pi$  of the distance of a star and have also measured with the spectroscopic its velocity of approach or recession, we can easily make a diagram of its real path in space (taking the sun as the center of reference) and thus predict all the circumstances of its motion.

For an example we may take the star Zeta Herculis. The observed parallax of this star 0.14 second, shows that its present distance from us is about 1400, 100 times that of the sun. It appears to move across the sky at a rate of 0.01 second a year, which, at that distance demands a real motion, at right angles to our line of sight of 12½ miles a second. But, from the spectroscopic work of several observers it is found that it is approaching us at the unusually rapid rate of 47 miles per second. It follows that this star is actually moving at a rate of 49 miles a second in a line which makes an angle of only 15 degrees with the line joining it to the sun. At this rate it travels every year a distance equal to 16½ times that separating the earth from the sun.

We can now make a diagram of the track of this star past the sun, such as is shown in the adjacent figure, in which  $S$  denotes the sun,  $A$  the present position of the star and  $B$ ,  $C$ ,  $D$ ,  $E$ ,  $F$ , its future positions at intervals of 25,000 years.

A cursory glance shows how much more rapidly this star will appear to be moving when it is nearest us (some 30,000 years hence) than it does now.

More detailed consideration shows that at that time it will appear as bright as Arcturus does now and have a proper motion of more than 20 seconds per year—greater than any star has at present.

It will certainly be a remarkable object then, but can hardly retain its present name Zeta Herculis, for it will have moved northward and westward about 75 degrees into a region of the sky which is now assigned to the southern part of Ursa Major, and 100,000 years hence it will be in Leo.

This is a somewhat exceptional case, for the track of this star is nearly near the motion in very little time.

But it is a star now from have got far their present end of a thousand years. Arcturus, which is now nearest point though 2750, far away from will then be at far away again about half as now while it moved some 40 westward, is to the region by Corvus—other hand is and slowly and will in all moved but 1½ west of its position Antares, brilliant bright place are even, and will change their place by only a degree or so in all this time. Altair, on the contrary, is a near neighbor and is still approaching us, so that in the year 10,000 it will be within the present boundaries of Herculis, more than twice as near, and fully five times as bright as at present.

All this may seem like very long range speculation, but a hundred thousand years, however long historically, is but a very short time from the standpoint of geology, as all students of that science agree. It is, therefore, much more than probable that could we be transported back to but a relatively recent geological period, say half a million years ago, we would find, on regarding the heavens, little or nothing recognizable in the way of constellations or individual stars (except a few groups like the Pleiades). But at that time, the main features of the present land surface of the earth were not greatly different from what they are

now, and so we see that the "eternal hills," perishable though they may be, are in all likelihood more lasting than the constellations, though very far from being as enduring as the stars.

### The Heavens.

Turning to our map, we find upon it all the stars of which we have spoken. Arcturus is high in the south, seeming at first glance almost overhead. Spica is lower down, and to the right, and Regulus is rising in the southeast. Hercules, with Corvus above and Lyra below him, is east of the south, and Aquila, with its bright star Altair has just risen. Ophiuchus and Hercules fill the southeastern sky. Centaurus is low in the south, and Hydra in the southwest, with Leo, Virgo, Cancer, and Corvus above it. Gemini and Auriga are setting in the west and northwest, and the Great Bear hangs high above them. Ursa Minor and Draco are above the pole, Cepheus and Cassiopeia low in the north, and Cygnus in the northeast.

### The Planets.

Mercury is a morning star all through May, but is best observable at the beginning of the month, when he rises about 4.30 A. M. Being, however, south of the sun, he is not favorably placed for view. Venus, having passed through conjunction with the sun on April 24th, is now a morning star, and rapidly moves out of the twilight. At the end of the month she reaches her greatest brilliancy being about 11 times as bright as Sirius, and 120 times as bright as a standard first magnitude star. She rises about 4 A. M., and can be followed with the unaided eye long after the sun has risen.

Mars is likewise a morning star in May, rising about 5 A. M. in the middle of the month.

Jupiter is in Sagittarius, and rises about 11 P. M. on the 10th. He is too far south to be well observable until some time after midnight.

Saturn is evening star at the beginning of the month, setting at 9.40 P. M., but the sun overtakes him and on the 26th the two bodies are in conjunction, and the planet unobservable.

Uranus is in  $\alpha$  (Serpentarius, observable in the hours before daybreak. Neptune is in Gemini, and is about four hours high at sunset.

The moon is near  $\alpha$  A. M. on the 6th in her first quarter at 7 A. M. on the 13th, full at 7 A. M. on the 20th, and in her last quarter at 7 P. M. on the 27th. She is nearest the earth on the 15th, and remotest on the 20th. During the month she passes by Mars on the 2d, Mercury and Venus on the 4th, Saturn on the 7th, Neptune on the 11th, Jupiter on the 21st, Uranus on the 26th, and Mars again on the 31st. Princeton University Observatory.

### Water Softening Methods

METHODS of water softening are not only of great practical value for preventing boiler scale, but are useful in dyeing, laundry and other branches of industry, as is well known. We wish to speak of the use of aluminum for this purpose. A European method consists in filtering the water upon the compound oxide of "permutite," which is a double effluve of alumina and soda obtained by an industrial process. Contact with it causes the lime of the water to give soluble salts of soda by double decomposition, and the filtering matter is transformed to lime salt, this being removed by a common salt treatment. Still more interesting is the new process which consists in allowing the water which is to be used in boilers to flow over a simple aluminum plate with embossed surface. It is said that such water will no longer give boiler scale, and it will even loosen up the scale already in the boiler. Such water should be used soon after the treatment, or be kept in tanks painted inside. It is not known just what changes take place in the water, and perhaps the dissolved substances become insoluble. As it is said to be so satisfactory in its action, we doubt the water has dissolved a certain amount of aluminum, which would certainly make of the dissolved alumina, how the best of conditions for the use of the water.

NIGHT SKY: MAY AND JUNE

This picture shows a portion of the big battery of Packard trucks which plunged into the relief work of flood swept Dayton

## THESE PACKARD TRUCKS HELPED TO PUT DAYTON BACK ON THE MAP

Following the Dayton flood, thirty-eight Packard trucks were used twenty-four hours a day to carry relief supplies and clean up the town

**T**HE Citizens Relief Committee issued the call for help at noon March 29. Two hours later, eight Packard Trucks were loaded onto a special relief train at the Packard factory. Within twenty-four hours, these trucks were at work in Dayton. Ten other Packard trucks were sent by special train from Cincinnati. These vehicles, with the large battery of Packards owned by the National Cash Register Company, formed the backbone of the transportation outfit used in relief service.

Dayton streets were choked with wreckage and debris. With all other methods of transportation rendered useless, necessity demanded motor trucks and they made a magnificent response.

The Packard trucks worked in water so deep that it was necessary to cover the radiators to avoid flooding the engines. In the stress of continuous emergency work, the trucks received no mechanical attention. It was a situation that called for 100 per cent efficiency and the Packards met this demand.

Sixteen hundred dead horses and many carcasses of other animals were removed by the Packard trucks within a period of three days. United States army officers say this prompt work averted an epidemic. Members of Dayton's Relief Committee state that the Packard trucks were a big factor in making the city fit for habitation.

**The people of Dayton know that when necessity calls the Packard delivers. What will you do when your test comes?**

HEADQUARTERS  
DAYTON MILITARY DISTRICT  
DAYTON, OHIO

Dayton, Ohio, April 17, 1918.

Packard Motor Car Co.,  
Detroit, Mich.  
Gentlemen:

We are both pleased and grateful to report that during the past three weeks of most extraordinary service, Packard trucks have rendered invaluable and continuous service. The work has been continuous day and night over almost impassable streets. Without motor trucks it would have been impossible to have distributed relief supplies.

Very truly yours,

*[Signature]*  
Adjutant General

THE NATIONAL CASH REGISTER COMPANY

INCORPORATED IN OHIO  
NATIONAL CASH REGISTER COMPANY, DAYTON, OHIO  
DAYTON, OHIO

Dayton, Ohio April 9, 1918

Mr. Alvin Hensley,  
General Manager, Packard Motor Car Co.,  
Detroit, Mich.

Dear Mr. Hensley:

Your letter of April 8th is received, and I take the earliest opportunity of writing to thank you on behalf of the Dayton Citizens' Relief Committee for the excellent assistance rendered by the Packard Motor Car Co., in our time of stress.

At the time we appealed to you motor trucks were our most pressing need, as we had the greatest difficulty in getting provisions for hungry people to the different points in the city for distribution. Your promptness helped to avert the situation.

Sincerely yours,

*[Signature]*

### The Smallest Automobile

A miniature which is probably the most diminutive practical working car in existence is illustrated in the accompanying photograph. It was designed and built by Joseph Newman of London and the little toy is driven and controlled entirely by his little son. Freely five years old, who takes his little sister and brother for rides in it. Mr. Newman built the car with his own hands. It took thirteen months to complete the work. This car is equipped with a two-cylinder gasoline engine of 2½ inch bore and the engine is intercooled with a fan. The power is transmitted by chain and belt to the four axle. The steering gear consists of a rack and pinion which moves the belt from an idler to an active pinion. The mechanism is so constructed that when the youthful chauffeur takes his foot off the pedal the belt is moved to the idler and the brakes are applied. The car is equipped with electric lights supplied from a 4 volt accumulator. The miniature automobile is fitted with an exhaust valve and is in every way the exact counterpart of larger automobiles. It will be observed that the car is provided with a top which may be brought forward when the weather is inclement.

Just like grown folks.

Underside of the baby auto.

Immense burl on a walnut tree.

Sawing down a tree single handed.

### A Black Walnut Burl

WRIGHT defines the word burl as an overgrown knot, or excrescence on a tree. These gnarled and warty excrescences, known also as burrs, are not formations of a considerable interest to the cabinet and furniture makers. On a recent visit to Mr. Vernon Virginia the writer photographed a remarkable excrescence on a walnut tree which is located just about 50 feet in front of Washington's tomb. By measuring the diameter of the trunk which is 15 inches four feet above the ground with that of the burl, it is seen that this is no small specimen of a burl. Though sometimes found lower, they rarely occur so high up on the branches and attain such an enormous size as this one. Most of them are on the main trunk of the tree and occupy a space equal to one half the diameter of the tree. This peculiar growth is sometimes caused by a fungus, which attacks the cambium or growing tissue and results in an abnormal development. The walnut tree is frequently attacked by this fungus and some specimens may be found with a number of burls. It may also be due to some mechanical injury to the cortex, or at other times to the sudden felling of a previously shaded tree to the light, as in the case where such boring trees are removed. From this peculiar growth is obtained the most beautiful grained wood for cabinet work. Although the wood is more difficult to work, yet the beautiful variegated colors, bird's eye markings and graceful wavy grain far surpass those of any other wood in lucrative design and color.

A six-ton truck hauling a twenty-three-ton boiler.

Pumping out a flooded cellar with a motor fire engine.

Utilizing power developed by testing tractors.

120 pounds pump pressure through three lines of 2½ inch holes, 500 feet in length, with a 1½ inch smooth bore nozzle on each line. The test lasted twenty minutes. The engine makes 750 revolutions per minute and it drives the pump at 1,000 revolutions per minute.

### Guide for a Lumberman's Saw

IN order to enable a lumberman to use a two-handed saw without the aid of a second man, a Canadian has devised the guide shown in the accompanying illustration. A pair of tongs are provided which may be clamped to the tree, the jaws of the tongs being formed with teeth adapted to fit into the bark of the tree. The handle of the tongs pass through sockets formed in a guide bar to which they are made fast by means of a pair of thumb screws. The saw rests on a carriage that is adapted to travel along the guide bar as the saw is fed into the wood. A constant tension is provided by a weight on the end of a chain that passes over a pulley at one end of the guide bar and is attached to the carriage. With this arrangement the lumberman operates the saw from one end while the other is supported by and is free to slide in the carriage. A twenty ounce weight or if preferred, a heavy clock spring is sufficient to feed the saw into the tree. With this arrangement a man may corner or notch a tree and cut on wedges. A tree of any size may thus be cut down single handed.

### Hauling Forty-five Tons With a Six-Ton Truck

IN the earlier days of motor trucking, a truck capable of carrying its load with a reasonable degree of reliability and economy was thought to be doing very well indeed and nothing better was asked of it. While even today there are motor trucks that are rather hard pressed to fulfill these conditions, it may be said that the majority of machines capable of doing a little better than might be expected from the normal rating. A case in point is that of a six-ton truck with hydraulic transmission of power which recently made a very heavy haul with success. The accompanying illustration shows the truck and its trailer for the time being—a huge contractor's truck weighing, without load, 12½ tons and loaded with a boiler weighing 25 tons and the total trailer load being 37½ tons. The motor truck, weighing 1¼ tons, was loaded with 6 tons of boiler fittings, etc., and the entire weight of 45 tons was moved up-town through the streets of New York, from Nineteenth Street to Fifty-eighth Street, at the rate of about 4 miles an hour, without difficulty either in hand line the great weight or in controlling the machine and the trailer. Several grades, severe when the load is considered, were negotiated. In order to handle this piece of work in the usual way about twenty horses would have been required, making a very long, awkward procession and blocking cross-street traffic considerably. The time in transit would have been several times greater than was taken by the machine and the damage to the pavement would have been greater owing to the slower speed and, consequently, the longer time the crushing weight would have been on the road.

### Obtaining Power from a Testing Plant

THE manufacturer of engines of any type, in the nature of the case, makes a thorough test of each one before it goes to the user. This is especially true of gas engines of any sort. Parts must be "smoothed up" and numerous adjustments made. The various devices such as magnetos, coils and distributors must be tested under hard service conditions. If the test is made directly on the engine, water heating and oil cooling is necessary. In this, an independent engine, running at a constant speed, and a water pump, driven by the engine, are used.

(Continued on page 109)

### Pumping Out Flooded Cellars With a Motor Fire Engine

ALTHOUGH the recent Ohio flood subsided even though the surface was drained of water there yet remained considerable work to be done in pumping out cellars. For this purpose, wherever possible, fire engines were used. The accompanying photograph shows a gasoline pumping engine at work at Columbus Ohio drawing water out of the cellar of a house No. 10. This sort of work put the fire pump to a severe test, for the water was muddy and sandy. However the pump shown in the illustration is of the multiple stage centrifugal type and was in no way injured by the grit mixed with the water. The pump could draw in water as large as three quarters of an inch in diameter without injury to any of its parts. The pump is driven by a six cylinder engine of 111 horse power capacity and it will deliver 1,000 gallons per minute at 120 pounds of pressure. At a recent test it drew water six and one half feet pumping 1,200 gallons per minute, at

The new Garford "Six" was designed contrary to the usual custom. Instead of utilizing, re-designing or substituting any old parts, this car is new in its entire construction.

From the smallest steel bolt to the handsome, graceful and noiseless one-piece-all-steel body, it is a distinct 1913 creation.

In it are embodied more new and practical six-cylinder improvements and conveniences than in any other "Six" built.

As one illustration, your attention is directed to the single, parabolic electric headlight, sunk flush with the radiator. This new method of lighting eliminates the rattling, cumbersome and unsightly

headlights that were always in the way. It gives the car a much cleaner and much more finished appearance.

And this is but one of the many exclusive Garford features.

A Garford owner recently wrote: "It strikes me that in the new Garford 'Six' you started your improvements from where all the others left off."

So, if you are in the market for a "Six," we believe we can offer you even more for \$2750 than most other manufacturers can for double that price.

Literature on request.

Electric Starter, which never fails to start instantly—water or steam.  
All lights are electric.

Big, single electric parabolic headlight, sunk flush with the radiator.  
Electric horn.  
One piece, all steel body,

steel Pullman car construction—no joints, no rivets, no wood.  
Wagoner Auto-Motor driven from the transmission.

60 horsepower, long-stroke motor—3½ in. by 6 in.  
Wheel Base, 120 inches.  
Tires, 36 x 4½.

Detachable Rim.  
Center Control.  
Left Hand Drive.  
Three Speed Transmission.

Full Floating Rear Axle.  
Bosch Magneto.  
Equipment—everything complete from tools to top.

# The Shoes You Wear

## Why They are Moderate in Price and Good in Quality

By George Brockholz

The Goodyear welt, which has been the leading factor in revolutionizing shoemaking and which has done much to reduce the price of shoes.

This lasting machine is provided with wipers for toe and heel, which draw the leather from all directions so that no wrinkles show on the shoe.

A scoring and channeling machine is employed in cutting the outside to conform with the shape of the bottom of the last with any desired extensions.

Goodyear improved sole-laying machine, which fastens the cemented sole to the shoe-bottom without tacks so as to leave a clean bottom.

The first fact that everyone should know about shoes is this: SHOES ARE BETTER IN QUALITY NOW THAN THEY EVER WERE AND VERY NEARLY AS CHEAP. Every other necessity of life has increased much more in cost.

Another fact: SHOES ARE NOT MADE BY A TRIST. No less than 1,200 factories are keenly competing with one another.

There must be some reason why shoes have not increased very much in price and why there is no shoe trust.

There is just one and only one reason and that is THE REPETITIVE NERVE-POLICY OF THE UNITED SHOE MACHINERY COMPANY.

### HOW THE UNITED SHOE MACHINERY COMPANY WAS STARTED

The United Shoe Machinery Company was organized in 1890. It was formed for the purpose of combining shoe manufacturers to make better shoes than they made before and to sell them to the public at the smallest possible expense.

Before the United Shoe Machinery Company was organized three important companies were supplying manufacturers with shoe machinery. THE COMPANIES WERE NOT COMPETITORS because each made a class of machinery for a special purpose.

Thus the Goodyear Shoe Machinery Company made machines which produced what are known as "welt" shoes, like those often worn by hand. In sewing a shoe by hand a thin and narrow strip of leather called a "welt" is first stitched to the inside and upper. The heavy out sole is then sewed to this welt so that the stitches fall outside and do not touch the foot. The inside being left entirely smooth. The welting and stitching machines of the Goodyear Company, named after Charles Goodyear, who developed the original invention and who was a son of the inventor of the Goodyear rubber vulcanizing process—completely displaced hand sewing. The welt shoe made on the Goodyear machines is the most comfortable shoe sold to-day—the finest product of the American shoe industry.

Besides the Goodyear Shoe Machinery Company, there were in the field the Consolidated and McKay Lasting Machine Company and the McKay Shoe Machinery Company. The Consolidated and McKay Lasting Machine Company made machines for lasting a shoe, a totally different operation from that performed by the Goodyear machines. The McKay Shoe Machinery Company made machines for attaching soles and heels by machine fastenings.

These three companies did not sell their machines to shoe manufacturers, but leased them and charged a royalty for their use. So long as the machines were in use they earned money for their manufacturers and for shoe makers. It was very necessary that they should not remain idle for a long time. Hence each of these companies established a repair service to keep its leased machines in best running order.

There were three NON-COMPETING companies dealing with the same shoe manufacturers and sending out three sets of repair men to the same factories. Clearly,

there was an unnecessary duplication of expense, for all of which the shoe manufacturer and ultimately the public paid. One set of repair men could easily keep all the machines of the three companies in order. One factory could easily make all three NON-COMPETING types of machines, so that the shoe manufacturer could obtain his equipment from one source just as housewives can obtain non-competing carpet sweepers and gloves or non-competing washboards and linen from a single department store.

This reproduction of an ancient decoration shows that, thousands of years ago, the Egyptian made shoes very much as the modern cobbler did before the invention of American shoe machinery.

From Dendera's "House of Horus" by courtesy of the British Museum. An interval of thousands of years separates this picture from the Egyptian hieroglyphic above. Yet the method of shoemaking disclosed by the same, when compared with the modern method, is the same. Modern progress has been made in the last generation, because of the systematic development of machinery in this country. (See p. 408, Scientific American.)

So, in order to lessen the expense of making shoes AND IN ORDER TO ENABLE THE PUBLIC TO BUY THE BEST SHOES AT THE LOWEST PRICE the three NON-COMPETING firms mentioned were consolidated in 1890 to form the United Shoe Machinery Company.

### THE BENEFITS OF THE LEASING SYSTEM.

Because the old leasing system has been continued by the United Shoe Machinery Company there is no shoe trust. You will understand why if you consider the way most manufacturers must start in business.

Suppose that you had decided to engage in a manufacturing enterprise. You would have to raise money not only for the purpose of acquiring a factory, but also of purchasing machinery. Indeed, you would spend much money on machinery—so much that when you sold your goods, you would have to make a proportional charge for the interest on the money invested in the machinery—about six per cent a year—and an other ten per cent a year for depreciation, repairs and the like. Because these fixed charges are large, because it takes much money to buy expensive machinery, many important industries—textile manufacturing, for example—are concentrated in the hands of a few companies. COMPETITION IS LIMITED.

This applies to nearly every industry EXCEPT SHOES. MANUFACTURING THE United Shoe Machinery Company's leasing method renders it possible to obtain the latest modern equipment for a small outlay so that the manufacturer can use his money over and over again in buying raw material and selling shoes. He does not have to make a charge for interest on money invested in shoe machinery or for the depreciable loss of the machinery.

THAT IS ONE OF THE CHIEF REASONS WHY YOUR SHOES ARE SO CHEAP. THAT IS ONE OF THE CHIEF REASONS WHY THERE IS NO SHOE TRUST.

THE SHOE MANUFACTURER PAYS ONLY FOR THE WORK THE MACHINE DOES, just as he pays only for the work that a man does.

### WHY THERE IS NO SHOE TRUST.

THE UNITED SHOE MACHINERY COMPANY DEALS WITH ALL SHOE MANUFACTURERS ALIKE. It matters not whether a man has a capital of a million dollars or only ten thousand dollars.

No shoe manufacturers have tried to obtain what they call "better terms" from the United Shoe Machinery Company, because they "use so much more machinery than the small manufacturer. If the United Shoe Machinery Company had listened to this argument there would be only a few large factories engaged in shoe manufacturing to-day. AND NO TRUST, FACTORIES. As it is, the shoe world which has thousands of dollars capital is able to compete with the smallest shoe maker. THAT IS ANOTHER REASON WHY THERE IS NO SHOE TRUST.

ONE AND ONE THINGS ONLY. A shoe is made by one machine, and one machine only. The three shoe-making operations must and must be done by the United Shoe Machinery Company. No other company can do them. That is why there is no shoe trust. That is why your shoes are so cheap. That is why there is no shoe trust.

Here is a table of royalties per pair paid by shoe manufacturers who lease machinery—

Goodyear men's work ..	\$0.00094
Goodyear men's women's work ..	0.00494
Goodyear turn shoes, women's and misses' ..	0.006
Men's and women's McKay shoes ..	0.01740
Children's McKay sewed shoes ..	0.01261

The average royalty received, based on the foregoing table, is about two and two thirds cents per pair. In reality it is less than even one and one third cents a pair for most of the shoes worn, because Goodyear welt shoes constitute less than one third the annual production of the United States.

SINCE THE ORGANIZATION OF THE COMPANY THE SAVING IN COST OF PRODUCTION OF MEN'S GOODYEAR WELT SHOES EFFECTED BY NEW AND IMPROVED MACHINES AND LOWER ROYALTIES HAS BEEN NEARLY 9 CENTS OR NEARLY DOUBLE THE TOTAL ROYALTY NOW PAID.

In return for this trifling royalty, the United Shoe Machinery Company provides American shoe manufacturers with a service that is unrivaled and unique. This service means the assumption of the whole cost of invention, experimental work, development, manufacture and depreciation of machines, the cost of constant care of machines to keep them at the highest point of efficiency, the payment of patents and the cost of administration. President Winslow of the United Shoe Machinery Company has repeatedly said "IT ASSUMES ITEMS OF EXPENSE AND RISK WHICH, UNDER ANY OTHER SYSTEM YET SUGGESTED, THE SHOE MANUFACTURER WOULD BE COMPELLED TO ASSUME HIMSELF, THUS SUBJECTING HIS BUSINESS TO A GREATER MACHINERY COST PER PAIR THAN THE AVERAGE ROYALTY HE NOW PAYS."

Is it any wonder that shoes are so cheap?

#### KEEPING SHOE MANUFACTURE UP TO DATE.

Nearly all the modern machines to be found in the bottoming department of a shoe factory were either invented or perfected by the United Shoe Machinery Company. Some of them were invented by outside inventors who were not connected with the United Shoe Machinery Company, but who sold their patents to the United Shoe Machinery Company at a fair price. But most of them were *deliberately created* by a highly paid staff, to meet the needs of shoe manufacturing. No really good mechanical idea is lost or abandoned for lack of mental or financial support. FROM \$500,000 TO \$200,000 A YEAR ARE SPENT IN IMPROVING OLD MACHINES OR INVENTING NEW MACHINES.

If the inventors of the United Shoe Machinery Company are ever convinced that some step in the making of a shoe can be accomplished in a simpler, cheaper and swifter way, all the resources of the company are placed at their disposal.

It used to be the practice, for example, to fit the parts of a shoe upper to the wooden last by hand. This operation was expensive. It required so much skill and patience that few thought it possible to carry it out by machine. Finally the leasing machine was invented which saved for a part of this operation. It was still necessary, however, by means of pieces to pull the leather over the steepest curves of the last before tacking it in place, and the inventors of the United Shoe Machinery Company were confronted with the problem of contriving a "pulling-over" machine. This problem was solved by them at a tremendous cost. They worked for years and they spent over one million dollars. When they had at last finished their task the famous "flex pulling-over" machine was produced. Despite all the cost and all the money that was expended on this machine, the shoe manufacturer pays a royalty of only three eighths of a cent for each pair of shoes made by its means, and this small royalty also covers the use of several other machines used in the pulling over process.

#### IT IS THEIR POLICY OF CONSTANTLY IMPROVING MACHINERY THAT HAS KEPT THE PRICE OF SHOES DOWN.

SCRAPPING MACHINERY. Many manufacturers in other industries CANNOT AFFORD TO DISCARD OBSOLETE MACHINES. They have invested too much money in them. Their manufacturing costs are often high because their equipment is out of date.

Every new invention produced by the United Shoe Machinery Company means the "scrapping" of hundreds of machines at the United Shoe Machinery Com-

PANY DOES NOT MANUFACTURE OR CONTROL ALL THE MACHINERY USED IN SHOE MAKING. Its service is confined largely to supplying the machines for lasting and bottoming shoes. In most factories machines for stitching, trevins, or finishing shoes, and for working sole leather can be found which were supplied by other companies, and which are installed side by side with United shoe machinery.

No shoe manufacturer need deal with the United Shoe Machinery Company if he does not choose to do so. He can equip his entire factory with machines which are not made by the United Shoe Machinery Company. If, therefore, the United shoe equipment is to be found in nearly all the 1,200 shoe factories in this country, it must be because it is so highly efficient, and because the manufacturer obtains not merely machines, but SERVICE—a service that enables him to fulfill his contracts to the day and TO REEL, SHIP TO THE PUBLIC AT A LOW PRICE AND A SMALL MARGIN OF PROFIT.

The only monopoly which the United Shoe Machinery Company enjoys is the legal monopoly granted by the patent laws of this country to every inventor. Any one who takes out a patent enjoys exactly the same kind of a monopoly. After the expiration of seventeen years—the term for which patents are granted in this country—any one is free to make use, and sell the invention disclosed in the patent.

The patents on many United shoe machines have expired. Others are free to appropriate the ideas disclosed in them, and others have done so.

*The existence and success of the United Shoe Machinery Company depend not only on efforts to overcome, but also on the invention of new shoe machinery, which will improve factory methods and which will improve the quality of shoes and keep the price down.*

#### HOW THE SHOE INDUSTRY HAS PROSPERED.

The liberal business policy of the United Shoe Machinery Company has made shoe manufacturing one of the leading industries in this country.

Before 1880, when the United Shoe Machinery Company was formed, the products of American shoe factories were worth \$25,000,000. Ten years later they were worth \$44,000,000—an increase of seventy per cent.

THE WAGES of those employed in American shoe factories INCREASED FIFTY-SIX PER CENT between 1880 and 1900, or from \$74,750,000 to \$122,500,000.

Our shoe exports were very small in 1900. They amounted to only \$1,810,058. In 1912 the value of our exported shoes was \$17,080,634—an increase of more than 850 per cent.

*This wonderful growth is due chiefly to the liberal business methods and the factory service policy of the United Shoe Machinery Company. The wealth of this country has been increased by millions because the United Shoe Machinery Company has systematically invented new machinery to lessen the cost of shoe manufacture and to improve the quality of shoes. AS A RESULT, THE SHOE INDUSTRY OF THE UNITED STATES LEADS THE WORLD.*

#### SHOES ARE NO LONGER LUXURIES.

Nowadays everybody wears shoes. Yet there was a time when every body when shoes were luxuries. A pair of handsewed welt shoes once cost from \$10.00 to \$10.00. Only the rich wore them every day. Yet now you pay from \$2.50 to \$5.00 for a pair of Goodyear welt shoes, much more comfortable and much better in quality than the \$10.00 handsewed shoes your father or your grandfather wore. What is more, you can, on average, American buy three pairs of shoes a year. Shoes are no longer a luxury.

JUDGE FOR YOURSELF HOW MUCH OF ALL THIS IS DUE TO THE POLICY OF THE UNITED SHOE MACHINERY COMPANY.

Advertisement

The "Ren" pulling-over machine, which was developed at a cost of over \$1,000,000, and which fits the parts of the shoe upper correctly to the last.

pany's expense. In a single year no less than four thousand machines have been withdrawn to make room for machines embodying the latest improvements. It does not matter if the shoe factory is large or small. All factories receive the latest improved machines. United shoe service is rendered to all on equal terms. THAT IS STILL ANOTHER REASON WHY THERE IS NO SHOE THIRST. THAT IS WHY EVERY SHOE FACTORY IN THE UNITED STATES, LARGE OR SMALL, ALWAYS HAS AN EQUIPMENT ABSOLUTELY MODERN. THE LAST WORD IN MECHANICAL INVENTION. THAT IS WHY THE PUBLIC IS ABLE TO BUY SHOES WHICH ARE CONCEDED TO BE THE BEST IN THE WORLD, AT A PRICE TO MEET EVERY PRICE.

#### THE REPAIR SERVICE.

Whenever a shoe machine is disabled the telephone or the telegraph will bring the nearest United Shoe Machinery expert to the shoe factory. Machines are thus maintained in perfect condition without charge.

Over five hundred repair experts are kept constantly on duty at the beck and call of shoe manufacturers. This expert service means that 100,000 entrusted machine parts must always be kept in stock in the Beverly plant of the United Shoe Machinery Company.

Over twenty-one million pairs of machines are sent out from the stock room annually to various branches of the United Shoe Machinery Company. AS A RESULT OF THIS REPAIR SERVICE EVERY SHOE MANUFACTURER CAN COUNT ON HIS MACHINERY, AND HENCE ON HIS PRODUCTION. His profits are assured.

THERE IS NO MONOPOLY. THE UNITED SHOE MACHINERY COMPANY

Fig. 1. A machine of which five thousand types of shoe machines are produced. It is used in pulling over the parts of the shoe upper to the last. It is the most important machine in the shoe factory.

Fig. 2. A machine of which five thousand types of shoe machines are produced. It is used in pulling over the parts of the shoe upper to the last. It is the most important machine in the shoe factory.

A loose lasting machine. This apparatus is used in fastening the heel and the sole preparatory to assembling the last.

## It Heals Tire Cuts

**You want to cut out tire repair waste—then you need this self-vulcanizing tire repairer—it does, itself, the extra work you've had to do yourself with the ordinary tire repair mastic. All you have to do is to apply it—it does the rest. Fills the cuts and holes, solidifies quickly and becomes like a part of the tire. No car owner can afford to be without it. Reduce tire expense 30 per cent—use**

# NARCO TIRE CUT FILLER

### Requires No Kneading

a non shrinking rubber compound heavy in rubber a combination cement, cut filler and mastic Refills and unites the torn place in the tire with a permanent plug of rubber more resilient than the tire itself Welds the loosened tread to the canvas body Supplied only in patent, collapsible tubes, with tapering spout

### Easy to Use

All you have to do is seal the cut thoroughly with **Gasline**—remove all oil, sand and other foreign matter. Insert the tapered spout into the cut and compress the tube smooths out the cut filler and the repair is completed. Allow it to heal overnight; in the morning it will have become like a part of the tire. Rivets tuck to the walls of the cut forming a union so perfect no road abuse can remove it.

This is the logical manner of tire repair. Every tire mobile owner in America should make **Tire C-Filler** a part of his repair outfit and begin saving in the cost now.

**Very Large Tube \$1.00, \$1.50 in Canada**

**Money refunded if not satisfied.**

**On Sale at All Dealers**

If yours can't supply you, we will  
Send dealer's name and \$1.00;  
in Canada, \$1.50

# TIRE NEWS

waterproofs the outer rubber casing of the tires and penetrates down into the inner fabric, protecting it from oil, air and moisture. Preserves the tires and prevents decay. Spread it over the surface of your tires after mending with Tire Cut Filler. Makes tires look like new.

There are limitations which point but don't pretest—insist on them.

**NATIONAL RUBBER COMPANY**  
4406 PAPIN STREET, ST. LOUIS, MO.

### Notes for Inventors

**Film for Moving picture Machine.**—George W Bingham of Brooklyn, N Y, assignor to Bingham-Cameron Company of New York has patented No. 1 045 502, a film for moving-picture machines which comprises a disk of celluloid or like transparent material provided with a series of pictures arranged progressively on the disk, the disk having an opening located in advance of the series of pictures and of sufficient size to permit free passage of the beam of light emanating from the projection apparatus of the machine.

**The Patents of the Bath Tr.**—The patents owned by the Bath Tr. recently disclosed by order of the Supreme Court of the United States cover principally enamelling processes. The major patent of the Bath Tr. was granted in 1890 to James Arrott Jr. Prior to his invention the enamelling powder was applied by a move attached to a long handle which was held by the workman with one hand, while the other hand was used by the workman striking the handle with the other hand thereby forcing the powder over the surface of the iron ware. The instrument was an impractic one not easily handled, and the workman was obliged to stoop down to fatigue heat and physical strain. Besides the flow of the powder was not continuous it was cast upon the metal in intermittent pulses causing in many instances the powder to be blown away from the surface and producing defective articles which either had to be thrown away or sold at a second. With Arrott's invention the above evils are lessened or disappear. The powder is blown over the surface rapidly causing instead of an intermittent flow of the powder as in the hand process a practically continuous flow. Both hands of the workman may be used to guide and hold the instrument. The parts of the instrument over the hand process are decided it is a more efficient and more economical. It makes a better article and in less time. There is no waste in seconds. The Bath Tr. has also secured patents in the U. S. in the U. S. at. Other patents owned by the Bath Tr. are those granted to E. Dithridge for a pneumatic move and a patent to William Lindsay for an enamelling process. The Bath Tr. patents are improvements on the Arrott invention.

**Protecting Moving Picture Films**—In a patent N 1047801 Isidor Kitzes the Philadelphia inventor suggests that he has found a way that if a nitrocellulose material is embedded in a film, the film will not be given off by bad material are neutralized the temperature remains stationary and no deterioration is ascertainable. When tw film, each in used in a roo-pole as a film embedded in a carbonate the film would raise the arbonate with the film which it the carbonate with infuse at a far as the carbonate for the reason that the aqueous products of the film embedded in the carbonate are neutralized as soon as they are given off. Kitzes also suggests that the film be embedded in a material that will protect the other film and to raise the temperature and explode. To protect their form, a film used for cinematograph exhibition he embeds the same in a carbonate. Kitzes also suggests that the film be embedded in a carbonate of antimony sodium and the equivalent for the storage of films has a lining impregnated with a material that will protect the glass surface of the film.

**A Running Support for Flying Machines**  
—Michael A. Parnano of New York city in a patent No. 1 040,581, shows a flying machine with trucks pivotally mounted on opposite sides of the main frame so they can swing transversely, and having wheels at their opposite ends and springs connected with the trucks on opposite sides of their pivotal points.

**A Convertible Tank Vessel.**—A novel construction of convertible barge and tank vessel is shown in the picture, No. 1049,490, to Charles F. M. Jack of New York city and thence to their heirs and assigns, a number of removable cylindrical tanks which are placed vertically on the hull so that they can be raised above and lowered

therein and adjustable means are provided for connecting the tanks together and to the sides of the hold.

**Resignations from the Patent Office Examining Corps**—Notwithstanding the increase in salary accorded the assistant examiners of the U S Patent Office resignations still continue frequent and during the past year the examining corps has suffered by twenty-four resignations. One of these was a principal examiner. During the same period several members of the corps have died including one principal examiner.

**Preventing Thumb Sucking**—**Jessie May Mitchell** of Clayton, Miss. has procured a patent No 1,048,569 for a thumb and finger-sucking preventer in which there is a stall fitted on the thumb or finger and a round disk too large to be inserted in the mouth is held by the stall on the end of the thumb or finger so the latter cannot be put in the mouth.

**Vermis Trap**—A patent No 1048470 the invention of Joseph Andel of Chicago Ill has issued for a vermin trap in which a hollow body has perforated walls and a honeycombed structure within the body for the reception of vermin and the perforated end walls are controlled by slides which have openings registrable with the openings and movable so the slides can be adjusted to close the wall openings

**A Trap Set by Foot**—Maurice F. Richardson of Southington Conn. has secured a patent No 1 048 586 for a spring trap which has a pan and a latch to hold the jaws open and is provided with lateral foot engaging extensions at the opposite sides of the jaws so that the trap can be set by the foot pressing upon the extensions.

**An Improved Beehive**—Francis Dan  
member of Norfolk Va. a well known  
inventor of beehive improvements is an-  
nouncing to Robert Johnson has secured patent  
No 1 048 950 for a beehive the body  
of which has a ledge for supporting frames  
or holders and a filling rail for the spaces  
above the ledge and provides a strip of  
treated material between the filling rail  
and the adjacent hive members

**An Electric Rat Trap**—Mihal Morawski of Pittsburgh, Pa. has secured a patent No. 1,048,995 for an electric rat trap which has a tilting platform and a pair of electrodes below the normal plane of the platform with the free opposing ends of the electrodes spaced apart and forming a mouth and operating to control and co-operate with the tilting platform.

**A Novel Form of Brake Head**—Frederick R. Cornwall of St. Louis assignor to Chicago Railway Equipment Company has secured a patent No. 1,045,261 for a brake head which has an opening of such size as to permit the introduction of the brake beam with overlying means for securing the brake beam in order to hold the head on the beam in suitable adjustment.

**A Gas-chain Fixture**—Frederick DeWitt Fitcher of Rochester N Y assignor to Welshach Light Company in patent No 1 046 489 shows a gas-chain fixture in which the gas-supply pipe extends adjacent to the links with its ends extending into socket members provided on the end links of the chain and connected thereto so that suitable connections may be made with said socket members to communicate with the gas-supply pipe carried by the chain

**Heating Hoistery Electrically** — The General Electric Company as assignor of Frederick M. Vogel of Pittsfield Mass., has secured patent No 1 048 514 for a device for drying hoistery in which there is an electrically heated metallic form corresponding generally to the shape of a stocking and having interexchangeable toe portions with a resistance conductor extending into the form and the toe portions so that the form may be heated throughout

**Reasoning by Centrifugal Casting.**—Reasoning from the dental practice of taking impressions of cavities and then casting by the aid of centrifugal action fillings to fit the cavity, the writer heard it suggested recently that some one might invent a means of producing well filling and suitable hollows by taking impressions of the prepared hole and then casting in a tin centrifugally, something like a shell of the shell.

### How Patented Inventions Have Increased the National Wealth

IN these days when great industrial dragons of capital guard every door of business opportunity, it is fortunate to know that there is one open window left.

During the past session after a bill was introduced to restore the rights of inventors in their inventions, Congress had the opportunity of hearing from the largest correct manufacturer in the United States, the biggest manufacturer of carpet covers, the best-known manufacturer of inexpensive watches, the manufacturer of the most advertised alarm clock in America, the two best-known safety razor manufacturers in the country, the largest manufacturer of cameras and photographic supplies in the world, all the photographer and tailing machine manufacturers in the United States, and most of the manufacturers of the specialties that newspaper and magazine advertising have made household words. Besides these, Congress also heard from the leading inventors of the country, the members of the Inventors' Guild, most of the engineers and electrical and commercial associations, and, finally, from Mr. Thomas A. Edison himself.

What these men had to say about the calamities which would follow if the rights of inventors were not restored to the Committee on Patents, that the Committee decided not to pass this Bill for the present. For all that, it will probably be presented at the coming session, for which reason its objectionable provisions should not be lost to view.

These manufacturers and inventors all told one story to-day: invention, protected by patent, is in all commercial activities the chief, and often the only way by which business independence may be attained.

All this explains why Americans lead the world in invention, why the patents taken out in the United States average nearly 40,000 a year, and why the aggregate number, 1,100,000, and why the patents issued by the United States are nearly equal, in annual output and in aggregate amount, to all the patents issued by Great Britain, Germany and France combined. Lead cut to end, the patents which have been issued by the United States Patent Office would reach three times around the world. Placed in a pile 10 feet square they would form a mass twice as high as the Washington Monument.

How tremendously patented inventions have contributed to the prosperity of the United States appears from the growth of industries depending entirely on inventions.

In the generation between 1880 and 1910, the value of our iron and steel manufactures leaped from \$207,000,000 to \$1,377,000,000, an increase of 565 per cent. Between 1880 and 1910 the output of sewing machines grew from less than \$4,500,000 to over \$28,000,000, an increase of 532 per cent. Between 1880 and 1910 the production of agricultural implements increased from less than \$21,000,000 to over \$145,000,000, an increase of 595 per cent. In the generation from 1880 to 1910 the output of photographic apparatus increased from \$145,000 to nearly \$14,000,000, an increase of 1,117 per cent.

Coming down to more recent examples of manufactures covered by patents:

In the decade between 1899 and 1909 the output of automobiles leaped from less than \$5,000,000 to over \$940,000,000, an increase of 4,890 per cent; the production of wire increased from less than \$6,600,000 to nearly \$60,000,000, an advance of 847 per cent; the output of photographs from about \$2,000,000 to nearly \$13,000,000, a growth of 550 per cent; the production of cash registers and calculating machines from about \$5,500,000 to nearly \$24,000,000, an increase of 336 per cent; the output of patented food preparations from \$20,000,000 to \$126,000,000, a growth of 530 per cent; the production of portable gas from a little over \$1,500,000 to over \$4,000,000, an increase of 166 per cent; the output of photo-engraving from \$1,000,000 to over \$11,000,000, an increase of 1,000 per cent; the output of safety razors from less than \$1,000,000 to over \$11,000,000, an increase of 1,000 per cent.

The greatest care in every detail makes the APLCO "the starter that never stops starting"

A corner of our testing rooms

## Every Aplco Electric Starter

that is finished in the Apple Electric Co.'s plant is submitted to a rigid final inspection by a corps of engineers under the direction of Mr. Vincent G. Apple himself. He is unwilling to risk the slightest possibility of any imperfection; the Aplco electric starter is his greatest achievement and he is determined that anyone who is fortunate enough to buy a car equipped with the Aplco system shall have no reason to regret his choice.

Electric starters are new to most of you buyers of cars, in fact they are a little new to the car manufacturers themselves. But they are not new to Mr. Apple. He had his first electric starter out on road tests several years ago, since then his best efforts and those of his engineers have been directed towards correcting any shortcomings developed by long continued service. Any good plant can make a starter that begins well and

gives results for a few thousand miles. Mr. Apple has been working on the other kind.

The Aplco electric starter, as it is found this season in 1913 cars, is the best, the most efficient and the most reliable and the lightest electric starter that can be put into an automobile.

This is the kind of starter you've been needing, it's the kind you want on any car you buy this year or next.

### Superior Points of the Aplco System

The whole Apple system is built in one plant, under the final supervision of one man. Everything—dynamo, motor, batteries, controllers, are built to work with each other with mechanical precision, they must test out together. Vincent G. Apple stands back of the entire system, not a part of it. All this is very different from some of the most widely advertised starters which are composed of units of which only part are made by the firm which offers you the starter. Some make the dynamo and buy the batteries and motors elsewhere, as-

sembling the units, and so on. The result? The generator designed by one man does not properly feed the battery made in the other man's factory, for instance—the user complains to the car builder, who refers him to the starter maker, who blames the battery manufacturer. Between them all, you—the owner of the car—get no satisfaction.

#### Other Inconveniences Eliminated

There are no sliding or exposed gears, no pedals to push, no meters to watch. The glow of a small lamp

shows whether the system is working properly. One lever on the controller is all you have to deal with.

The Aplco regulator forces the dynamo to supply an absolutely uniform voltage at all speeds above that equaling two miles per hour of the car.

The storage battery is a specially designed form of the Aplco battery and maintains the Aplco quality in every particular. It is usually carried on the running board of the car, but may in some cases be placed under the floor of the car or under a seat. The battery requires no attention after

being installed other than the occasional addition of a little distilled water to replace losses through evaporation.

The controller contains the operating switches for all electrical appliances on the car, and the regulator, all under lock and key. It is very compact and can usually be placed on a panel under the driver's seat within easy reach.

The driver can start the engine, light, dim or extinguish his lights, and operate his electric horn all from the controller, and need not even change his position to do so.

If you want to bring your car or boat up to date with Aplco lighting system or Apilow lamps if you want an Aplco house lighting outfit, send for bulletins on these subjects.

The Aplco starter for your 1914 car must be installed by the builder before delivery. Take it up with him or his agent now. We do not supply individual starter outfits for installation on cars now in use.

**The Apple Electric Co., 62 Canal St., Dayton, Ohio**

**You - as a tire bill payer - now demand a vise-like rim grip with no cutting or breaking above the rim - and here it is →**

It's the *rim* as much as the *road* that wears out your tires.

So we said to our Engineers:

"You must build us a tire with Perfect 3-Point Rim Contact."

*They did*—and they also added the No-Pinch Safety Flap for inner tube protection in

Then we called in our Chemists and said:

"Tire buyers are demanding a tough, flint-like, but resilient tread—a tire made of lustrous young rubber—a tire giving the

utmost mileage at no additional expense."

And the answer is

# Vitalized Rubber Diamond {No Clinch} Tires

Perfect 3-Point Rim Contact

Here is a No-Clinch tire that appeals to the hard-headed, shrewd tire buyer—the man who insists on easy riding comfort and a good, liberal mileage.

Each point of rim contact in a tire is a point of support. Where the points of rim contact are not perfect, undue pressure is brought to bear at an unsupported point of the tire.

Then what happens? The result is a terrific strain on the tire that results in rim troubles, breaking above the bead and separation of the tread from the carcass.

All this is overcome in the Diamond No-Clinch because the three-points of rim contact are absolutely *mechanically perfect*—the annealed steel cable wire bead holds with a vise-like, rim-grip.

Add to this the No-Pinch Safety Flap for inner tube protection, the Vitalized Rubber advantage, the famous Diamond Safety (Squegee Tread) and you have bought rubber shod mileage that has no equal at any price.

**So this time buy Diamond Vitalized Rubber Tires—**

## Why Do Bearings and Gears Wear Out?

**FIRST**, let us analyze friction. Friction is the resistance or retarding force set up by two surfaces rubbing against one another. Each surface exerts an almost constant pull on the particles making up the other surface. The surface of the two which are the better withstand this frictional pull will be the surface to remain unworn. The bearing metal should be so designed as to give way before the steel. But the bearing metal should not give way to this pull too easily. That would mean quick bearing wear.

THE cohesive strength of the bearing metal should approach that of the steel as nearly as possible, but so it keeps under it. Such a metal is

# NON-GRAN

Non-Gran is a special metal, made by a special process, which is used for bearings and gears. It is a metal which is so designed that it will wear away before the steel, but it will not wear away too easily. It is a metal which is so designed that it will wear away before the steel, but it will not wear away too easily. It is a metal which is so designed that it will wear away before the steel, but it will not wear away too easily.

FRITON is a metal, and that metal which will wear away before the steel, but it will not wear away too easily. It is a metal which is so designed that it will wear away before the steel, but it will not wear away too easily. It is a metal which is so designed that it will wear away before the steel, but it will not wear away too easily.

2767, 2768, 2769, 2770, 2771, 2772, 2773, 2774, 2775, 2776, 2777, 2778, 2779, 2780, 2781, 2782, 2783, 2784, 2785, 2786, 2787, 2788, 2789, 2790, 2791, 2792, 2793, 2794, 2795, 2796, 2797, 2798, 2799, 2800, 2801, 2802, 2803, 2804, 2805, 2806, 2807, 2808, 2809, 2810, 2811, 2812, 2813, 2814, 2815, 2816, 2817, 2818, 2819, 2820, 2821, 2822, 2823, 2824, 2825, 2826, 2827, 2828, 2829, 2830, 2831, 2832, 2833, 2834, 2835, 2836, 2837, 2838, 2839, 2840, 2841, 2842, 2843, 2844, 2845, 2846, 2847, 2848, 2849, 2850, 2851, 2852, 2853, 2854, 2855, 2856, 2857, 2858, 2859, 2860, 2861, 2862, 2863, 2864, 2865, 2866, 2867, 2868, 2869, 2870, 2871, 2872, 2873, 2874, 2875, 2876, 2877, 2878, 2879, 2880, 2881, 2882, 2883, 2884, 2885, 2886, 2887, 2888, 2889, 2890, 2891, 2892, 2893, 2894, 2895, 2896, 2897, 2898, 2899, 2900, 2901, 2902, 2903, 2904, 2905, 2906, 2907, 2908, 2909, 2910, 2911, 2912, 2913, 2914, 2915, 2916, 2917, 2918, 2919, 2920, 2921, 2922, 2923, 2924, 2925, 2926, 2927, 2928, 2929, 2930, 2931, 2932, 2933, 2934, 2935, 2936, 2937, 2938, 2939, 2940, 2941, 2942, 2943, 2944, 2945, 2946, 2947, 2948, 2949, 2950, 2951, 2952, 2953, 2954, 2955, 2956, 2957, 2958, 2959, 2960, 2961, 2962, 2963, 2964, 2965, 2966, 2967, 2968, 2969, 2970, 2971, 2972, 2973, 2974, 2975, 2976, 2977, 2978, 2979, 2980, 2981, 2982, 2983, 2984, 2985, 2986, 2987, 2988, 2989, 2990, 2991, 2992, 2993, 2994, 2995, 2996, 2997, 2998, 2999, 3000, 3001, 3002, 3003, 3004, 3005, 3006, 3007, 3008, 3009, 3010, 3011, 3012, 3013, 3014, 3015, 3016, 3017, 3018, 3019, 3020, 3021, 3022, 3023, 3024, 3025, 3026, 3027, 3028, 3029, 3030, 3031, 3032, 3033, 3034, 3035, 3036, 3037, 3038, 3039, 3040, 3041, 3042, 3043, 3044, 3045, 3046, 3047, 3048, 3049, 3050, 3051, 3052, 3053, 3054, 3055, 3056, 3057, 3058, 3059, 3060, 3061, 3062, 3063, 3064, 3065, 3066, 3067, 3068, 3069, 3070, 3071, 3072, 3073, 3074, 3075, 3076, 3077, 3078, 3079, 3080, 3081, 3082, 3083, 3084, 3085, 3086, 3087, 3088, 3089, 3090, 3091, 3092, 3093, 3094, 3095, 3096, 3097, 3098, 3099, 3100, 3101, 3102, 3103, 3104, 3105, 3106, 3107, 3108, 3109, 3110, 3111, 3112, 3113, 3114, 3115, 3116, 3117, 3118, 3119, 3120, 3121, 3122, 3123, 3124, 3125, 3126, 3127, 3128, 3129, 3130, 3131, 3132, 3133, 3134, 3135, 3136, 3137, 3138, 3139, 3140, 3141, 3142, 3143, 3144, 3145, 3146, 3147, 3148, 3149, 3150, 3151, 3152, 3153, 3154, 3155, 3156, 3157, 3158, 3159, 3160, 3161, 3162, 3163, 3164, 3165, 3166, 3167, 3168, 3169, 3170, 3171, 3172, 3173, 3174, 3175, 3176, 3177, 3178, 3179, 3180, 3181, 3182, 3183, 3184, 3185, 3186, 3187, 3188, 3189, 3190, 3191, 3192, 3193, 3194, 3195, 3196, 3197, 3198, 3199, 3200, 3201, 3202, 3203, 3204, 3205, 3206, 3207, 3208, 3209, 3210, 3211, 3212, 3213, 3214, 3215, 3216, 3217, 3218, 3219, 3220, 3221, 3222, 3223, 3224, 3225, 3226, 3227, 3228, 3229, 3230, 3231, 3232, 3233, 3234, 3235, 3236, 3237, 3238, 3239, 3240, 3241, 3242, 3243, 3244, 3245, 3246, 3247, 3248, 3249, 3250, 3251, 3252, 3253, 3254, 3255, 3256, 3257, 3258, 3259, 3260, 3261, 3262, 3263, 3264, 3265, 3266, 3267, 3268, 3269, 3270, 3271, 3272, 3273, 3274, 3275, 3276, 3277, 3278, 3279, 3280, 3281, 3282, 3283, 3284, 3285, 3286, 3287, 3288, 3289, 3290, 3291, 3292, 3293, 3294, 3295, 3296, 3297, 3298, 3299, 3300, 3301, 3302, 3303, 3304, 3305, 3306, 3307, 3308, 3309, 3310, 3311, 3312, 3313, 3314, 3315, 3316, 3317, 3318, 3319, 3320, 3321, 3322, 3323, 3324, 3325, 3326, 3327, 3328, 3329, 3330, 3331, 3332, 3333, 3334, 3335, 3336, 3337, 3338, 3339, 3340, 3341, 3342, 3343, 3344, 3345, 3346, 3347, 3348, 3349, 3350, 3351, 3352, 3353, 3354, 3355, 3356, 3357, 3358, 3359, 3360, 3361, 3362, 3363, 3364, 3365, 3366, 3367, 3368, 3369, 3370, 3371, 3372, 3373, 3374, 3375, 3376, 3377, 3378, 3379, 3380, 3381, 3382, 3383, 3384, 3385, 3386, 3387, 3388, 3389, 3390, 3391, 3392, 3393, 3394, 3395, 3396, 3397, 3398, 3399, 3400, 3401, 3402, 3403, 3404, 3405, 3406, 3407, 3408, 3409, 3410, 3411, 3412, 3413, 3414, 3415, 3416, 3417, 3418, 3419, 3420, 3421, 3422, 3423, 3424, 3425, 3426, 3427, 3428, 3429, 3430, 3431, 3432, 3433, 3434, 3435, 3436, 3437, 3438, 3439, 3440, 3441, 3442, 3443, 3444, 3445, 3446, 3447, 3448, 3449, 3450, 3451, 3452, 3453, 3454, 3455, 3456, 3457, 3458, 3459, 3460, 3461, 3462, 3463, 3464, 3465, 3466, 3467, 3468, 3469, 3470, 3471, 3472, 3473, 3474, 3475, 3476, 3477, 3478, 3479, 3480, 3481, 3482, 3483, 3484, 3485, 3486, 3487, 3488, 3489, 3490, 3491, 3492, 3493, 3494, 3495, 3496, 3497, 3498, 3499, 3500, 3501, 3502, 3503, 3504, 3505, 3506, 3507, 3508, 3509, 3510, 3511, 3512, 3513, 3514, 3515, 3516, 3517, 3518, 3519, 3520, 3521, 3522, 3523, 3524, 3525, 3526, 3527, 3528, 3529, 3530, 3531, 3532, 3533, 3534, 3535, 3536, 3537, 3538, 3539, 3540, 3541, 3542, 3543, 3544, 3545, 3546, 3547, 3548, 3549, 3550, 3551, 3552, 3553, 3554, 3555, 3556, 3557, 3558, 3559, 3560, 3561, 3562, 3563, 3564, 3565, 3566, 3567, 3568, 3569, 3570, 3571, 3572, 3573, 3574, 3575, 3576, 3577, 3578, 3579, 3580, 3581, 3582, 3583, 3584, 3585, 3586, 3587, 3588, 3589, 3590, 3591, 3592, 3593, 3594, 3595, 3596, 3597, 3598, 3599, 3600, 3601, 3602, 3603, 3604, 3605, 3606, 3607, 3608, 3609, 3610, 3611, 3612, 3613, 3614, 3615, 3616, 3617, 3618, 3619, 3620, 3621, 3622, 3623, 3624, 3625, 3626, 3627, 3628, 3629, 3630, 3631, 3632, 3633, 3634, 3635, 3636, 3637, 3638, 3639, 3640, 3641, 3642, 3643, 3644, 3645, 3646, 3647, 3648, 3649, 3650, 3651, 3652, 3653, 3654, 3655, 3656, 3657, 3658, 3659, 3660, 3661, 3662, 3663, 3664, 3665, 3666, 3667, 3668, 3669, 3670, 3671, 3672, 3673, 3674, 3675, 3676, 3677, 3678, 3679, 3680, 3681, 3682, 3683, 3684, 3685, 3686, 3687, 3688, 3689, 3690, 3691, 3692, 3693, 3694, 3695, 3696, 3697, 3698, 3699, 3700, 3701, 3702, 3703, 3704, 3705, 3706, 3707, 3708, 3709, 3710, 3711, 3712, 37

**A \$100,000 Game Electro-magnet.**—In view of the scientific results which are obtained with the extremely powerful electro-magnet at the Zurich Polytechnicum upon the design of Prof. Weiss, it is now proposed to construct a still larger one at Paris by Messrs. Weiss and Cotton which will reach as high as 75,000 gauss and it is to use electric current to the extent of 300 horse-power. The estimated cost of the magnet is less than \$40,000. It will be placed at the disposal of all scientists who are engaged in researches which require a specially strong magnetic field.

**Metal Filament Street Lighting.**—A test was recently made in Switzerland to determine the relative efficiency of arc lamps and metal filament lamps for street lighting purposes. Two streets of equal length were lighted, one with the arc lamps and the other with the metal filament lamps. The arc lamps were of 10-ampere capacity and the incandescent lamps were of 600 candle-power. The choice between the two forms of lighting was left to twenty-nine trolley-car motormen. Twenty-five of these were in favor of the metal filament lamp, chiefly because it did not irritate their eyes as much as the arc lamp.

**Emergency Lighting Plant for Ships.**—To avoid the horrors of a sea disaster at night the lights are apt to be put out by the flooding of the electric generating plant. But it is necessary to depend upon a plant located where it is liable to be flooded? Experiments are being made now on a large British vessel that is under construction with a gasoline electric plant which may be placed on the bridge deck. This set will not only supply the light but the wireless telegraph apparatus as well so that the occupants of the vessel may be supplied with light and the means for calling for assistance in the very moment of complete submergence of the vessel. This generating set will be used only in emergencies.

**Electric Control of Furnace Stoking.**—A number of the recently built blastfurnaces of the French fleet are fitted with a very effective apparatus for securing a regular stoking of the furnaces on the Niortaise system. The engine room is an electrical device at the engineer's hand which sends automatic signals to the furnace quakers a certain number of times an hour in order to control the stoking. This is initiated by a lamp located in the furnace quakers having a button for each furnace and when the automatic signal comes on an electric bell rings and the panel lights up, indicating for instance five shovels in furnace No. 1 and so on in turn for the other furnaces. The number of shovels which are required for stoking can be varied at times according to need by properly setting the apparatus.

**Oil-engine Generating Plant.**—One of the most successful electric tramway systems in the north of Italy has lately been installed at Parma. This called for the setting of a central station of some size in order to furnish the current needed for all the tramway lines running through the city and it is worthy of note that gas or oil engines are used for this plant. One of the engines is of the new Diesel type and runs with heavy oil as fuel. The oil is vaporized by a compressed-air spray and thus furnishes a gas which runs the engine on the explosion principle. The new 800 horse-power Diesel engine installed in the Parma station ranks among the large ones yet to be built and is of the upright type with four cylinders. Coupled to it is the dynamo which furnishes the current for tramway use. Other dynamo in the station are run by gas engines which work upon producer gas.

**Milan-Varese Electric Railroad.**—According to the latest recent information about the reorganizing of the Milan-Varese electric railroad it is probable that the needed increase of traffic the State railroad department to whom the railroad belongs decided to purchase a supply of current from a Milan electric plant and now adopts the 3-phase system at 40,000 volts upon a line running from the electric station to the electric plant. The line there are erected seven substations which take the place of the four old ones and all the substations were built there so as not to stop the traffic while the work was going on. Owing to rapid work it was possible to open the new line last summer. The line has a total length of 10 miles. It carries the 3-phase, 40,000-volt current and changes it to direct current at 600 volts on a tie on the third rail of the road. The overhead wiring connecting up the various substations and the central station is about 60 miles long. The former Varese electric plant of small size is no longer used for the supply. Owing to the fact that the electric road passes through a very active industrial region, the traffic increased so much after the opening of the line in 1911, that a thorough change was needed. However the new line was made and thus made it necessary to use a new type of electric locomotive which has recently been put into service and takes a 200-ton passenger train at 65 miles an hour, or a 400-ton freight train at slower speed, owing to the advantage of the electric drive. The locomotive has a number of safety devices, to a remarkable number of times per day it is carrying a heavy traffic.

**The New Capital of Australia.**—Which is to be built in New South Wales, has been named Canberra (scent on the South Sea). The ceremony of laying the foundation stone of the commencement column was carried out March 12th by the governor-general and a numerous company of officials and military. The ceremony of laying the column, which stands before the site of the capital building, if possible, be composed of stones from all parts of the British Empire.

**The Red Radical in Science.**—An alcoholic solution of the skin of a red radish serves as an excellent indicator for acids and alkalis. In the presence of acids the colorless solution turns pink while with basic alkaline solutions—it turns yellow. It is well known that many plant extracts such as litmus and animal products like the cochineal bug possess this property of developing marked colors with acids and bases but no other indicator is so easily made.

**Gelatin Protection.**—Gelatin belongs to the class of protective colloids possessing the ability to surround minute particles of suspensions with a film that prevents their aggregation into precipitates. Since the formation of crystals is a growth from very small nuclei this process is retarded by a small amount of gelatin. Commonly this principle is applied in the making of marshmallows. The presence of a little gelatin does no harm in fact it is a food and it effectively prevents the crystallization of sugar within the marshmallow. Commercial ice cream contains some gelatin for the same purpose, to prevent the graininess of sugar crystallization. But further than this the gelatin surrounds the particles of casein in the milk with a protective film which hinders curdling and greatly aids digestion.

**Antibacterial Microbes.**—That amine colors have a marked action upon various kinds of microbes appears to be established by the recent work of S. Krogberg. He studies the effect of a certain number of amine colors upon microbes such as typhus coli and others and finds that amine compounds in general seem to destroy microbes thus being even in greater degree than phenols and. Of the different bacteria he examined he finds that the typhus bacillus is the most readily affected. On the other hand he remarks that not only can there exist differences in the mode of destroying power between the different amine colors for the same microbe which are easily explained by diversity in chemical nature but he also notes that the same color compound does not possess an equally strong power upon different kinds of microbes. In fact a certain number of amine substances may be considered as destroying one species of germs without necessarily being active as regards another species.

**Rock Paintings in Tunis.**—Rock paintings of an interesting kind in the south region of Tunis are described by M. Henri Roux and published in the *Revue Tunesienne*. One of those was noticed on a rock wall in the Djebel Bly and it represents very likely a combat of men in conventional drawing and animals which it is difficult to identify. The age of this painting raises quite a controversy among specialists and some think that it is contemporary with the Berber civilization that is intermediate between the stone age and the age of metals. According to this idea it belongs in the last part of the neolithic period. But M. Roux wishes to place it at a later date, in the middle of the bronze age. The age of the neolithic period it being due to a civilization which is more ancient than the Berbers and M. Gubert also thinks that it is the work of negro people to whom are due the flints of the neolithic age found in North Africa.

**Effect of Manganese and Zinc on Spores.**—The combination of zinc and manganese has been the subject of research known as *capripilus super* forms the object of research made by Bertrand and Javillier at the Pasteur Institute some time ago they found that each of these metals taken separately had a very striking effect upon the growth of the yeast *Saccharomyces cerevisiae*. In their experiments their recent researches show, and examining the results they find that the weight produced is greater when the two metals are used together than when only one of them is employed. It is seen that the productive effects of the two metals are not additive in these cases. It appears that the manganese is absorbed by the spores in the presence of zinc, they find that the manganese accumulates in larger percentage when associated with zinc than when alone, but the reverse effect does not seem to be proved. For in one test the same amount of zinc was absorbed regardless of the presence of manganese. Again the two metals have a catalytic action and thus influence the overall absorption of mineral elements by the spores, and even small amounts of the metal will produce this effect. Three times the higher order of plant manganese fertilizer increases the amount of ash. The above results bear out the author's theory that the rare elements of the organism are far from being without physiological interest, and are not even to be considered as simple energy carriers. They are in fact essential for the development of the cell and are catalyzers which are necessary for the chemical nature of living bodies.

**Brake Capacity and Efficiency.**—As the result of recent experiments by Prof. H. V. of Purdue University has been demonstrated that for protection all around efficiency the brakes of a car should be designed in the proportion of 1 square inch of braking surface to every 10 pounds of gross car weight. In this respect efficiency is taken to mean sufficient to prevent a car from stopping to a stop from full speed within a reasonable distance without excessive over-heating. Large brakes it is pointed out are inefficient in that they are liable to lock the wheels early thus reducing retarding capacity and causing undue tire wear.

**Improved Water Wheel for Trucks.** To obviate the sliding possibilities of steel wheels on stone-covered roads and to eliminate comparatively expensive rubber tires a manufacturer of commercial vehicles has developed a new type of tire compound essentially of rope fiber. The rope is cut into sections approximately three inches in length and after being impregnated with pitch the sections are subjected to hydraulic pressure to impart to them the required curvature and homogeneity. Afterward they are fastened within the steel felloe channels by the simple expedient of bending the edge of the channel inward. It is stated that an expenditure of 6,000 can be obtained and that the rope tires are inexpensive and easily attached.

**Bus Lines for Rural Use.**—It is the opinion that the present development of the gasoline omnibus which is now such a success is to have quite an influence upon the question of passenger traffic upon roads. Hitherto the bus has been furnished with light electric or steam railroads for use in the country districts but it often happens that there is comparatively little traffic on such lines. In some cases the estimated profit from such roads are not enough to warrant a great layout of capital so that the power wagon omnibus will fill the needs in the best manner. An example of this is seen in Italy where the bus lines are developing considerably throughout the country so as to avoid incurring a great amount of capital which it would be difficult to recoup. The present type of omnibus applies to local traffic as well as to tourist lines.

**Benzol as a Corrector of Fuels.**—Great as is the attention that has been directed toward benzol abroad as an alternative fuel for gasoline engines would seem to have overlooked the fact that it is as a corrector of the heavier distillates has been furnished with light electric or steam railroads for use in the country districts but it often happens that there is comparatively little traffic on such lines. In some cases the estimated profit from such roads are not enough to warrant a great layout of capital so that the power wagon omnibus will fill the needs in the best manner. An example of this is seen in Italy where the bus lines are developing considerably throughout the country so as to avoid incurring a great amount of capital which it would be difficult to recoup. The present type of omnibus applies to local traffic as well as to tourist lines.

**Warning Conveyed by Engine Starters.**—Despite the very evident advantage of the many forms of engine starters which during the past year have sprung into such prodigious numbers that the average motorist has the engine device their use may tend to hinder instead of lower fuel bills unless due care is taken. That is to say it is such a simple matter to start the average engine with such a device that the motorist may overlook the fact that his carburetor is not properly adjusted for greatest efficiency and that is particularly so with the varying demands of present-day fuels. When the old fashioned hand crank is used the effort required to start the engine may serve as an indication of the adjustment of the carburetor for proper adjustment means easy starting. With the coming of the engine starter however this means of judging of adjustment, even if it is comparatively rough is lost.

**New High-speed Gasoline Engine.**—A new type of internal combustion engine designed to run at 6,000 revolutions per minute and to develop 100 horsepower, has just been put on the market by an English manufacturer. While it is chiefly intended for aeronautics use, a similar model for automobile use is in preparation. The engine has eight steel cylinders of 2½-inch bore and 2½-inch stroke arranged in V shape on a tubular steel crankcase. On the end of the crankshaft is a spur gear which drives a large reduction gear having a ratio of six to one. The cylinders are set on the crankshaft in such a manner that the motor develops fifty horse-power at the normal speed of 1,000 revolutions per minute and weighs complete only 112 pounds, it works with a compression of eighty pounds per square inch. The engine was designed by Granville B. Bradshaw while working on the staff of the Royal Aircraft Establishment. The two-cylinder engine develops 100 horsepower at 6,000 revolutions per minute and developed 13 horsepower.

## Saving a Cathedral With a Diver

### How Winchester Was Furnished With a New Foundation

By J. W. Overend

ONE of the earliest and most famous of English cathedrals is Winchester, second only to the historic Westminster Abbey in London as a national shrine. It was built by William of Wykeham statesman, prelate, and a master builder. In 1070 it took some fourteen years to build. To this day much of this Norman builder's work remains as he left it, particularly in the north and south transepts, in the cores of the piers, and the walls of the nave, and in the crypt. But some of it represents the reconstruction which was rendered necessary by the fall of the central tower in 1107.

The Normans were great builders, and they spent little time in designing, for they must have had their designs ready during a period of an initial building age never before witnessed in England. There might have been no time to dig properly for the foundations, or to find out if the ground on which they intended should be the base of the great cathedral, was safe or worthy to support the huge structure which rose upon it.

The great minster must be feared, the long nave stretching ten, twelve, or even fourteen bays, the transept, the choir with its great apse must arise, and the lantern tower above the crowding of the transept upon its four great piers. It seems as if Wykeham thought his piers too large in area ever to be pressed down into the earth, and too mighty ever to be bowed under the confidence in his erections was complete and his faith unlimited.

But the impression was false, and not lasting. The duration of very many of these massive works was short indeed, and the appearance of rock like solidity altogether misleading. The huge piers were mere cases of external juck wrought stones filled with rubble generally, imperfectly grouted together.

So it came to pass that the Norman central towers in most cases either soon fell down, or had to be rebuilt, or buttressed up, in order to avoid the ruin which their fall would otherwise have caused, and Winchester was among the cathedrals to have their towers rebuilt. From the very beginning of the building of the cathedral it has had tremendous troubles, and its history has been marked with disaster owing to the unfortunate selection of a poor geological site of marl and peat on which to erect it. The appearance of omissions cracks in the walls, vaulting, and crypt caused them in power to take very serious steps in the spring of 1905 to remedy the defects, and to get at the root of the evil.

The work was taken in hand by Mr. T. G. Jackson, a distinguished English architect, whose work in the restoration of Ilminster Palace, Bath Abbey, and other notable buildings of historic interest placed him in the front rank of authorities on the preservation of old buildings.

The impression of the architect is that the pile began to settle as soon as it was finished, and it has, of course, been getting worse as years and centuries have come and gone. The walls, especially on the south side, had also bulged outward, the inclination from the perpendicular being in one part as much as two feet in forty-four, and in another place an inch in a foot.

Diver at work on the cathedral foundations.

A view back in the south transept, showing the foundations.

The method of arriving at the cause of settlement has been unique and in fact it is questionable if ever a cathedral has had a new foundation inserted after standing through a period of centuries like Winchester. Under direction of the architect, Mr. Jackson, a pit was dug on the south side of the eastern entrance of the choir. Beneath a 10-foot depth of topsoil a marly clay of 8 feet thickness was reached, and in this stratum was found a raft of beech logs, placed horizontally in two cross layers. Below the clay was a layer of peat, and beneath that a gravel bed charged with clear water free from mud. This was the direct cause of the mischief. Water existed in the subsoil, and under the enormous pressure the peat had yielded, causing the walls to sink and to be thrust out by the pressure of the vaulting. The peat bed was found to be 8 feet 6 inches thick, but directly under the footings it was compressed to about 6 feet. The compressed peat really formed ligulae. The building had sunk from 2 to 3 1/4 feet.

In order to remedy the defective foundations the walls, vaults, etc., had to be carefully underpinned down to the gravel below the strata of peat. The water rose in the pit to the top of the clay deposit. The architect consulted Mr. Francis Fox, a celebrated civil engineer, whose success in solving the water difficulty in connection with the ventilation of the Stimpson Tunnel in Switzerland stamped him as being the man to handle the Winchester problem. On his suggestion, a diver was employed, and the following mode of working was pursued.

First the walls of the cathedral were well grouted to fill up all the cracks. Then the foundations were attended to in sections of 5 or 6 feet at a time. The walls were dug through the topsoil, exposing the foundations. Then with the aid of ordinary excavating and light pumping the clay and some of the peat was removed until it was necessary to stop pumping, after which the diver entered the hole and removed the remainder of the peat, running drifts under the walls from 8 to 10 feet long. Bags of ready mixed concrete were then lowered down to him with which he paved the excavation, cutting them open to allow the material to spread over the surface. After four layers of bags were laid and the material had been allowed to set it formed a barrier to further inflow, and the water was pumped out of the pit. Then the foundation work was finished by ordinary means and bricklayers.

It is worthy of note that the beech logs which formed the raft on which had slumbered the walls of a great English cathedral for centuries were in an excellent state of preservation, considering their position.

We are indebted to Messrs. Messrs. Jackson & Co., Ltd., for the above information, and for the plan, which the accompanying drawing was prepared.

## Air Resistance to Falling Bodies

By A. A. Bonarville

IN THE spring of 1915 there appeared in the *Scientific American* an advertisement asking for college men to make measurements of the time-rate of falling bodies over long distances of free fall. Such an advertisement as this, in which it was stated that the work might be done during vacation time, naturally brought a great number of replies, the writer of this article being one of those interested.

My correspondent and man back of the entire plan proved to be Mr. George Cleveland Hicks of Chicago, Illinois. Mr. Hicks is primarily a business man, a director in an enterprising corporation. Aside from his business interests he is interested in the laws of nature, and is willing to spend his money to study and have others investigate for him.

For several years Mr. Hicks has been interested in the subject of falling bodies, and especially in the rate of fall over long distances. He still has experimental notes taken twenty years ago, and adds to them all the while. This last year he has obtained the first real accurate evidence to verify his own private opinions on the subject, and he has had many different people at work for him in as many different places.

The laws of bodies falling under gravity alone, as first determined, are still used in practice to-day. The most commonly used equation is of the form

(1)

Equation (1) reads like this—the space through which a body will fall in a given time is equal numerically to one half the value of the acceleration of gravity, multiplied by the time squared.

Now the value of the acceleration of gravity is equal to the force necessary to support a unit amount of material in free space, or it is the change in velocity that a body will acquire if allowed to fall from rest during one second, roughly this is 32 feet per second, so we will say that the value of  $g = 32$  numerically without attaching any time or space units to it as a physicist would do.

Now putting that value into our equation we have  $s = \frac{1}{2} 32 t^2$ , and if we suppose a body falls during a time of 5 seconds then  $s = \frac{1}{2} 32 (5)^2 = 400$  feet. But if we try the experiment we will find that the body will not fall so great a distance in five seconds time.

There are two or more reasons for this—they are air resistance and air buoyancy. The latter is negligible unless very light bodies such as feathers or balloons are dropped, but if metal bodies are dropped the buoyant effect of the air is only about one hundredth of one per cent of the force of gravity, and so any retardation of the rate of fall of the metal body is negligible.

The other effect which causes retardation is that of air resistance. That is, the falling body must push the air out of its vertical path downward, and at high speeds this becomes a very considerable force. High speeds can be had in freely falling bodies only by using long distances. There are scarcely any data available on the subject. Prof. Hall of Harvard has done some work in his own laboratory. Attempts had been made, but without success, to secure the privilege of trying the experiment in the Washington monument.

The writer, with the assistance of others, worked on the problem this past summer at Toughneck Falls, New York. At that place there is a ravine with cliffs on either side 300 feet high. The gorge is 400 feet wide. A cable was stretched across from cliff to cliff and anchored. On this cable was a pulley which could be located directly over the middle of the gorge or at one side of the small stream at the foot of one of the cliffs. From this pulley a double line extended to the bottom, and by means of this line a steel measuring tape, a box with drop door to contain shot, marbles, gullies or similar objects to be dropped, and an electro-magnet with lead wire reaching to the ground, all would be raised to the height of the cable at the top. Through the lead wire extending to the ground a current could be sent through the electro-magnet, thereby causing the tripod in the box and allowing the bodies therein to fall over a distance of 300 feet. Distance was measured accurately with the steel tape. Time was recorded on a chronograph or revolving cylinder covered with paper on which a pen marked. This was controlled by another chronograph in the glass circuit as the one on the cable above, so that a signal was made on the chronograph at the instant the body started to fall. The falling body was caught in a sheet at the bottom at the end of the fall, and when it struck the sheet the burst was sufficient to jerk the sheet at the camera when it was focused, and thus by means of electrical devices made a signal on the chronograph through the electro-magnet operating the pen. Actual time of fall could in this way be measured to a hundredth of a second.

When the value of  $g$  is known, the value of the acceleration of gravity, the equation  $s = \frac{1}{2} g t^2$  can be used to find the time of fall.

Box from which shot was dropped and sheet in which it was caught

Time of fall for shot of different sizes.

The Washington Falls and cable stretched across the gorge in the experiment with falling bodies.

Glass balls, loaded glass plates and shot of various sizes were used for falling bodies. Later in the summer more data were taken at two other places where air currents were not so troublesome.

A set of curves was plotted showing the time required for shot of different sizes to fall a given distance.

It is to be hoped that Mr. Hicks will continue these experiments, and so be able to furnish further data on the subject.

## Moor-burning in Germany

A COLONIAL "smoke nuisance," from which the greater part of Europe once suffered more or less, is now rapidly abating with the decadence of the time-honored German custom of burning the moors. This custom, together with certain atmospheric phenomena to which it gave rise forms a curious chapter in the history of German agriculture.

About three per cent of the total area of the German Empire is moorland, i. e. a soil consisting of peat formed by the partial decomposition of mosses and other vegetation, and in its natural state unfit either for cultivation or grazing. The problem of utilizing the moors, both in Germany and in the other countries of northern Europe, has received a wholly satisfactory solution in recent times, thanks to the efforts of numerous moorland experiment stations, moor combustion, besides for moor culture, and so forth.

Several scientific methods of moor culture are now in vogue, and there is a large literature on the subject in Germany. The problem is, however, an old one, and was partially solved centuries ago by primitive methods, one of the most popular of which was moor burning. The great stronghold of this custom, which was introduced from Holland at the beginning of the eighteenth century, was the district in the northeastern corner of Germany called East Frisia, and here it still flourishes to some extent.

The essential features of the process are as follows: The land is usually first drained by open ditches, in order to dry a shallow layer of surface soil. In the autumn the turf is turned over or set on end, and allowed to dry all winter. During a spell of dry weather in May or June the clods of turf are piled in heaps and set on fire. The fire is generally started on the leeward side of the pile, in order to ensure slow and thorough combustion. The results of this process are that the land is cleared of waste vegetation, and the layer of peat is spread over the moor, and the underlying ground is improved in its hygroscopic and chemical constitution by the heating which it undergoes. The land thus prepared is generally sown at once to buckwheat. After the harvest the whole process is repeated, and another crop is grown the following year. No fertilizers are applied. It is found, however, that the productivity of the land diminishes year by year, and after six or seven years the moor is burned anew. It used then be abandoned, and require 20 or 30 years to recuperate. As compared with the modern methods of thorough draining, rolling mixing with the subsoil, and otherwise permanently reclaiming the moors, the burning process is so wasteful of land that it has generally been given up except in districts remote from settlements, where the cost of the land is insignificant.

One of the most serious objections to moor burning is the huge volume of smoke which results from the smouldering of the imperfectly dried peat. This smoke is carried by the wind for hundreds and even thousands of miles. There is a saying that "when the moors are smoking all Germany smokes it," but this hardly expresses the matter fully, for there are many cases on record in which the smoke from the North German moors has been observed in the form of a characteristic haze—the so-called "fog" or "moor smoke"—as far away as Spain, Italy, and Greece. This phenomenon is analogous to the smoke-haze from forest fires so often observed over vast areas of the United States in autumn.

## Useful Cements

ONE of the simplest hard cements is the well known mixture of litharge and glycerine made to a stiff paste. It sets hard as a rock, and is oil proof. A solution of water glass mixed with powdered calcium carbonate serves the same purpose.

A mixture of bottled lime-oxal and fire clay yields a better than most cements, though sulphur mixed with glass powder is also ranked as very resistant to chemicals in general.

A good stone cement is made by mixing two parts of magnesium oxide, one part of magnesium chloride, powdered stone to suit as a filler and water to make a stiff paste. Basic magnesium chloride is formed

### New Light on Diabetes

MOST people think of diabetes as a chronic disease. It is erroneous. Diabetes is a disease whose characteristic symptom is an excess of sugar in the blood. This excess, the kidneys work hard to remove. To hold them responsible is as absurd as to blame the thermometer for extremes of temperature.

Soluble sugar is a vital necessity to the organism, but an excess is a dangerous poison which must be excreted.

The latest investigations of sugar metabolism show that the formation and excretion of sugar depend on a very complicated and delicate balance of the action of several organs, including the central nervous system, the sympathetic nervous system, the pancreas, the suprarenal glands, the pituitary body, the thyroid gland and the epithelial bodies. Any disturbance of this balance which is attended by a delicate adjustment of "control," may lead to the presence of an excess of sugar.

The value of these discoveries, which are very clearly stated by Dr. J. H. H. H. in *Prometheus* is most notable since they afford hope of an earlier diagnosis and prompter treatment of a particularly distressing ailment.

The chief source of sugar in the body is the starch consumed in food and other cereal food and potatoes and other vegetables. This is a small part of the sugar we need because it is in soluble form, as of grape-sugar, milk sugar, cane-sugar, and fruit sugar. These enter the blood directly because of their solubility, but the starches, which are insoluble in water, must be acted on by digestive ferments and food then enters the blood before they can be thus taken up and carried to the various tissues. This is partly accomplished by the saliva, but chiefly by the pancreatic juice in the small intestine, after the food has passed the stomach.

From here the sugar passes on to the liver and afterward enters the general circulation, to be carried by various parts of the body, being especially required by the muscles.

If now the provision of sugar exceeds the current demand, the excess is stored, partly in the form of insoluble animal starch (glycogen), whereby water is eliminated, and partly in the form of fat. The latter is stored in the greatest variety of places, the former chiefly in the liver and muscles.

Animal starch is found not only from starch and sugar, but from albumen, when an excess of this is furnished by such food as meat and eggs, but the amount thus formed is insignificant compared to that from the so-called carbohydrates.

Hunger and labor both diminish these stores in the organs, the liver and muscles first, and then the demand. The process is so neatly adjusted in the healthy body that despite the large variations in the amount of carbohydrates consumed, on the one hand and in the output of energy, on the other, there is never a great excess or decrease, the percentage of sugar in the blood remaining steadily between the narrow limits of 0.1 per cent and 0.15 per cent.

It is only when the body loses its power of burning sugar in its tissues that the sugar content of the blood is unduly augmented, and must be removed. Naturally the kidneys, the other organs, may suffer degeneration through overwork.

When, by reason of increased use of sugar, the sugar content of the blood rises far below the normal level, and other deposits of animal starch, such as the muscles, receive the order to transform some of this into soluble sugar and supply it to the circulation. This message is transmitted by the so-called "chromaffin" system, which is specially located in the suprarenal glands. The message tells the sugar to the place where required and gives it up to the needy cells. If the chromaffin system fails of its function because of some affection of the suprarenal glands, as in Addison's disease, the sugar content falls below the normal.

But here another factor must be considered, in the action of the pancreas. This gland is antagonistic to the suprarenal glands, in that it exerts an inhibitory influence upon sugar formation in the liver and other destinations. Hence, the pancreas and suprarenal glands tend to control each other, thus preserving the needed balance. But if the pancreas becomes diseased, while the suprarenal glands remain sound, the result will be an excess of sugar in the blood.

But both pancreas and suprarenal glands are themselves controlled by other regulators. The pancreas is subject to an inhibition from the thyroid gland. When this is unduly large the pancreas is checked in its function of burning sugar produced in liver and muscles. Hence, the two form a delicate balance of animal starch into sugar causes an excess of sugar in the blood, more work for the kidneys. "Consequently, we often observe the presence of sugar in the urine of patients suffering from an enlarged thyroid, as for example Heubner's disease or 'goitre-sugar.' This malady lowers the capacity to burn sugar.

Conversely, if the thyroid is insufficiently developed the pancreas is insufficiently checked in its inhibitory action on liver and muscles, with the result that the 'limit of tolerance' for sugar is raised. In this case even a large superfluity of carbohydrates in the diet will not cause accumulation of sugar, since the sugar content of the blood is diminished.

"The suprarenal glands, on their part, are under the control of the sympathetic nervous system. The French investigator, Claude Bernard, showed nearly two generations ago that the striking of a needle into a certain spot in the fourth ventricle of the brain was followed by the excretion of sugar in the urine, because the irritation thus induced passed over the *Nervus Sympathicus* to the liver and accelerated sugar formation. But this stimulus to the liver from the central nervous system goes by way of the suprarenal glands.

Claude Bernard's 'Function Diabetes' is in fact a purely suprarenal diabetes.

"To these correlations must be added the effect of the pituitary body, and that of the epithelial bodies of the *acromegaly* thyroid gland. The pituitary body acts in the same way as the thyroid, while the epithelial bodies (or epithelial corpuscles) act antagonistically.

"Hence, the enlargement of the pituitary, as seen in acromegaly, and the striking of a needle into a certain spot in the fourth ventricle of the brain, as done in the enlargement of the thyroid, while on the contrary, the enlargement of the epithelial corpuscles causes an increase of sugar tolerance."

Even these elaborate relations do not cover the full complexity of sugar metabolism, since some questions remain to be solved. But it is obvious that sugar in the urine may proceed from a great variety of causes, making the need of skilled diagnosis imperative.

### A Remarkable Flight in the Far East

THIS aviator Marc Fourcade made an aeroplane flight which is quite out of the ordinary during his stay at Singapore, flying in a brilliant manner across the island of Borneo, which is entirely covered with wooded tracts made up of cocoa and rubber trees, then flying above the Sultan of Johore's palace, this being situated on the other side of the strait, whose width is three miles. This flight is said to be the most dangerous which has yet been attempted, although the distance is only about 50 miles. It is also the longest aeroplane trip to be made in the tropical regions. The Sultan of Johore offered the pilot the sum of \$500, and the Singapore Government 'this raised a prize of about \$2,500 for the flight.

### Live Frozen Fish

TRANSPORTATION of live fish is an expensive matter from the fact that it requires from 1 to 4 gallons of water per pound of fish according to the kind, so that a railroad car having 10 tons limit for the load can carry but a few hundred live fish. One ton of live fish, Moore, Mr. Andrus and now use a method of freezing the fish in blocks of ice according to Letch's experiments, and can now transport a large quantity of fish in a relatively small weight of ice. The fish are at first contained in a large amount of water, then while the tank is placed in a closed space oxygen under pressure arrives upon the water, so that the greater part can now be drawn off and the fish remain in good condition in a very small amount of water, as the oxygen supplies their respiration. Freezing is now done by plunging the fish into the fish tank in a refrigeration tank, and in this way an ice block is obtained in which the fish are frozen, but will come to life again when thawed out. The block is wrapped around with suitable coverings and on the outside is put a heat-proof tin jacket, then the block is ready to be put in the car. In practice, such blocks can be piled up in refrigerator cars whose temperature is kept near the freezing point. Upon arrival at their destination, the fish are put through a very slow thawing process, which lasts for several hours. Naturally the necessity of such an important discovery has made somewhat of a sensation and gives rise to some incredulity as well, but the author has now published a brochure on the subject in which he gives a very complete account of his methods for such a purpose. He has taken a picture to give a description of the process and there are also photographs of the specimens at an early date, but would mention at present that the specimens have been given some well-known scientists, also several, and they identify them with real diamonds. Naturally they

### Artificial Diamonds

A PARIS engineer, M. de Bormont, claims to have produced minute diamonds by an electric furnace process, the largest of the specimens measuring nearly one-tenth of an inch. Naturally the authenticity of such an important discovery has made somewhat of a sensation and gives rise to some incredulity as well, but the author has now published a brochure on the subject in which he gives a very complete account of his methods for such a purpose. He has taken a picture to give a description of the process and there are also photographs of the specimens at an early date, but would mention at present that the specimens have been given some well-known scientists, also several, and they identify them with real diamonds. Naturally they

were put through all the necessary tests in this case. The process is based upon the electrolysis of carbonic oxide in the electric furnace by the use of direct current, and the carbide is decomposed in such way that one of the poles becomes surrounded with a blackish and waxy substance in which a series of minute carbon crystals or diamonds are observed, and these are separated by pulverizing and washing the substance. The experiments were made on a small scale, as lack of means prevented further work, but the results are so convincing that the author is encouraging it that the size of the diamonds increases with the length of time the furnace is left running, so that there is reason to believe that much larger sized ones can be obtained. The *Bismarck* American will soon publish an article on the Bismarck process.

### Preventing Bread from Getting Stale

FOR thousands of years mankind has been content with allowing its bread to get stale, and this fact has come to be considered unavoidable. It is the more surprising that researches by Dr. J. R. Katz at the Physical-Chemical Laboratory of the University of Amsterdam, have shown that it is in the power of man to do so much so that no need for allowing our bread to lose its toothsome. When kept in either at a very low or very high temperature, bread is in fact preserved "new" for some days at least, staling being due only to the ordinary temperature of about 60 degrees and common moisture.

In connection with Dr. Katz's experiments, bread was kept absolutely new for more than 40 hours at a temperature of 80 degrees Cent., while at a temperature of 30 degrees to 40 degrees it became only "half stale." At ordinary temperatures it of course grew rapidly stale, in order to appear to become "fresh" at temperatures below freezing point.

Dr. Katz accordingly recommends keeping the newly-baked bread at temperatures of 80 degrees Cent. and upward, thus keeping the crust absolutely new, whereas the crust by allowing water becomes limp and flexible. If the bread be then put back again into the oven for a short time the crust will give up its water, thus becoming hard and crisp as before. An even simpler course is preserving the bread in cold storage rooms kept at a temperature of about 30 degrees Cent. The crust will be sufficiently dry, the crust likewise remains hard and crisp so that the bread eaten after a considerable time is equivalent to new bread.

Apart from its importance to the housewife this process is of the highest economical interest, relieving as it does the baker of the necessity of baking his bread by night.

### How to Read Through Opaque Paper

A VERY remarkable experiment which any one can repeat with very little trouble has been unearthed by a contributor to *Prometheus*, in an old number of the *Mechanics Magazine* of the year 1858. Take a piece of paper of such thickness that, when it is laid upon a piece of printed matter the characters just show through, but cannot be read. Placing it over a printed sheet impart to it a circular motion to and fro, and to your surprise you will find that now you can read the print below the paper. It is rather difficult to explain this peculiar effect. The explanation offered in *Prometheus* is that the paper has a number of thin streaks in it, and by the circular motion of the paper, every part of the printed matter is exposed to turn underneath one or the other of the thin plates in the paper and thus the entire print can be read. However, that may be, the experiment is interesting and very simple, and affords for its performance only the simplest means imaginable.

### The Current Supplement

GRINDING wheel sparks are not only a somewhat spectacular accompaniment of the use of the wheel, but may be turned to useful account, as their appearance contributes to the initiation of the character of the steel from which they are struck. This point was illustrated by R. G. Williams in this week's issue of the *Supplement*—it will be remembered that in 1904 the Quebec bridge over the St. Lawrence River collapsed while in the course of construction. This plane adopted for a new bridge by the Canadian government are critically discussed and compared with the author's own design of Prof. G. Kiewit of St. Petersburg. Some deceptive practices upon the unwary buyer of scrap metal are laid bare—A simple method of measuring the heat-treated steel is given. The concluding lecture of the series delivered by Sir J. J. Thomson on the Structure of the Atom appears in this issue—A new variety of extreme ultraviolet is described by Irving Langmuir—A. D. W. Wright writes on the Atomic Theory and the Atomic Theory of the Universe—The author of the paper on the structure of the atom, Prof. J. J. Thomson, is presented in this issue—The author of the paper on the structure of the atom, Prof. J. J. Thomson, is presented in this issue—The author of the paper on the structure of the atom, Prof. J. J. Thomson, is presented in this issue.

## Inventors and Technical Schools

To the Editor of the SCIENTIFIC AMERICAN:

Mr. Kennedy's letter of the 29th calls attention to a most needed thing. The progress of any country depends largely upon developing new wealth, and your article on inventors and inventions quite clearly brings out this fact. Unfortunately, American manufacturers are not fully aware of this matter. They regard the expense of development as beyond them, which in many cases it doubtless is. The Germans are doing much better than we in this respect. Possibly because labor is cheaper.

We have, however, means at hand that could be used if proper agitation and education is made along this line. I refer to our technical schools. Manual training is being adopted by many schools, so that the student is given practical work along with his theory. These schools contain a large available supply of metals and tools which could just as well be employed on new work as in doing more or less useless work, as often happens now. If inventors could arrange with the school to develop the invention, the school would get the advantage of the students' work on something that requires advanced thought, while the inventor would get the advantage of the apparatus, experience, and theories which the school can give him. I think some work of this kind is done now, but I do not know of any systematic arrangement for the protection of the inventor, on which account he usually prefers to keep his invention to himself until perfected sufficiently to apply for patent. If the school could receive a certain percentage for developing the device and for assisting the inventor to market it, this matter could be profitable to the school and inventor both.

BEGUN, Mich.

CHARLES E. DUTRUE

## The Need of a Bibliographical Institute

To the Editor of the SCIENTIFIC AMERICAN:

Your editorial, "Why the Rich Man Might Do for the Schools," is very timely and interesting. You ask, "Why not found a bibliographical institute?" Perhaps the reason why it has not been founded is that it does not appeal to the imagination in the same way as does a library. But you are quite right in pointing to this as a matter of greatest importance. The multiplication of libraries. An Institute for Bibliographical research, such as the writer has advocated for many years, would supplement and aid the work of libraries and would result in a national organization of what might well be called the foundation of all knowledge. For bibliography answers the question "What do we know about this matter and how did we arrive at the present knowledge?" Anyone who tries to answer such questions will necessarily use bibliography as a means by which his problem must be solved.

It is now nearly twenty years ago that the writer, in a paper read before the New York Library Club and afterward published in the *Library Journal*, advocated an organization of bibliographical work through a pooling of the interests of a number of the larger libraries for the purpose of making their resources in many special fields more generally available.

Since then the subject has received the very closest attention on my part, and I have repeatedly brought it to the attention of libraries, bibliographers, and other scholars. From men of all quarters the proper reply has not with approval and interest, the need of a bibliographical institute in the interest of scholarship is fully appreciated by those who would benefit high.

Men of wealth have been approached through various channels in an effort to find someone who would come forward to assist this important movement, but so far in vain.

An effort is now being made to interest business men in the subject. Efforts are being made to show that bibliography can be made of direct service to the business community. This circular has been sent out to a number of prominent business men in Chicago calling attention to the value of research along these lines for both corporations and individuals. A "Circular on Research Institute" has been devised for the purpose of promoting the idea.

With the latest endeavor has been made along the line of convincing the intention of the writer is now, as he has always been, the same. He desires the scope of a bibliographical institute should be the point most of all to be kept in mind. The Institute should be a national organization of the scientific method. The Institute should be a national organization of the scientific method. The Institute should be a national organization of the scientific method.

be in readiness to make researches into definite subjects at the request of those desiring special information, it would also try to anticipate the needs of inquirers, and compile references on subjects of actual interest in advance of demand.

The writer has often been asked what relation this proposed Bibliographical Institute would have to the other institutes of this kind, notably the Institut International de Bibliographie at Brussels, and the Internationales Institut für Bibliographie, and allied institutions at Berlin. The answer is that it would complement these and, as far as possible, utilize their material. The Brussels Institute collects titles of all kinds, from all sources and of all dates, the Berlin Institute collects titles from the current year on a limited number of subjects. The Institute which the writer proposes would have for its object to collect titles from all sources and of all dates on a definite number of subjects, concerning which information is actually wanted.

While an institution of this sort should be independent, and not affiliated with another, for instance one of our large libraries, it might very well be organized in connection with a new kind of library, a library for libraries, containing books and periodicals too expensive and too little used for most ordinary science or college libraries to possess them. The establishment of such a library has been advocated several times.

If anybody who reads the above should be willing to assist in this furthering the idea to some geographical research along the lines suggested, he should communicate with the undersigned.

ARCEL G. H. JOHNSON

Chairman Committee on Research Institute Chicago, Ill.

## The Fallacy of Flexible Fabric Wings

To the Editor of the SCIENTIFIC AMERICAN:

I have read with much interest Mr. Grant Linton's letter on aeroplane design in your issue of March 24, 1913. In the present stage of the sciences every suggestion, if not too obviously absurd, is liable to serious consideration. Nevertheless, Mr. Linton's reasoning seems to be based on such an astounding lack of knowledge of the commonest facts of aerodynamics, that I am forced to doubt the validity of his conclusions.

He begins by stating that the forces acting on his piece of fabric are its weight, downward, and the wind backward, but he overlooks the third necessary factor to equilibrium, the upward and forward force of the cord or other sustaining means. How will he solve this problem in transferring his idea to an actual machine? Then he assumes us that the air stream is flowing horizontally as it meets the forward edge of the fabric, apparently unaware that Montgomery proved, as long ago as 1905, by using streams of water sprinkled with light chaff to indicate lines of flow that a current approaching a surface inclined to it at a positive angle is deflected upward to a considerable degree some distance in advance of the surface, which result has more recently been confirmed by injecting thin lines of smoke into wind tunnels.

Next he tells us that "there is of course a decrease in the absolute drift component of the air pressure, proportional to the decrease in the absolute lift." This statement can be true only for very small angles of incidence, for, for instance, if the free rear of the fabric drops slightly, so that its angle of attack changes from, say, 20 degrees to 30 degrees, there will be a decrease in the absolute lift, but an increase in the absolute drift.

Assuming, by analogy from the sailing vessel, Mr. Linton says that the sail automatically varies to the most favorable form under any conditions of wind pressure and direction of wind pressure. This statement is not true. Any mathematician knows that a sail ought to be brought to a relatively shallow curvature for reaching, and allowed to bag somewhat for running. The late A. Cay Smith, by means of a contrivance called the reach reel, which enabled the curvature of a sail to be varied slightly at will, succeeded in substantially doubling the speed of a number of racing yachts. Mr. Linton also does not seem to be aware that sails are not efficiently operative at angles of incidence as low as 5 degrees, which is about the maximum now found in efficient sails. However, it is not necessary to say just what he means when he says that "in both cases of vehicles the best efficiency could only be obtained by altering the length of the chord." Possibly he is thinking of variable area, a device that offers many advantages. However, it is not necessary to state that this about the best length for the chord of an aeroplane wing is one sixth of its span, and no noticeable gain in efficiency can be had by varying greatly from this proportion.

It is not necessary to state gravely when he asserts that "Full speed when auto is as regular as that of the highest type of automatic machinery." That the best aeroplane will undulate slightly in its flight path,

requiring an occasional touch of the elevator to keep it horizontal, just as a ship, and for that matter, an automobile, requires an occasional touch of the wheel to hold it to a straight course. The resulting constant changes in the angle of incidence of course cause a constant varying lift, and consequently an uneven speed. The magnitude of this speed variation will probably surprise Mr. Linton very much if he will consult the reports of the speed tests made on a Zeppelin blimp at the Aeronautical Institute of St. (Vr, an abstract of which will find its way into the *Aero and Hydro* on page 25. The gentleman does not seem to know that the ability to vary the speed of horizontal flight within wide limits is a most desirable quality of the aeroplane. The Cody captures a victory by its speed of level flight between 48.5 and 72.4 miles per hour, a range of 40.4 per cent, contributed largely to its winning of the British military trials.

The belief in the parabola as the only correct basic curve for wing sections, a belief which Mr. Linton asserts with much positiveness, belongs to the ancient days when we knew absolutely nothing of the actual conditions around an aeroplane wing in flight. The belief might be correct if we were dealing only with the principles of dynamics, as a matter of fact, we have to deal also with the properties of a gas, and recent discoveries seem to indicate that effect due to the latter is the more important. No successful aeroplane in use today employs a wing of purely parabolic curvature. Practically all employ compound and irregular curves. The wing of the *Voisin* is a case in point. Its design being wholly empirical, and with such wings they manage to fly fairly well and to return in useful work a very large proportion of the energy expended. Moreover, when a test is made to prove, the facts in actual use which are based on the curves are given on the average, better results than those approaching the parabolic form. But it is as silly to expect any definite and universally correct curve for a wing section to be discovered as it is to expect a single curve to be always the correct one for the waterline section of a ship's hull.

Personally, I have often observed a piece of fabric suspended by one edge in a current of air and I never saw one curve in a reversely S-shaped curve, the dense for aeroplane use without beginning to flap or undulate. This effect is in part due to the fact, first demonstrated by Montgomery, that the air flowing around the curve tends to assume a rotary or eddy motion, and in part due to the fact that the fabric is, by its structure, uniformly loaded. In proposing to uniformly load his full-sized piece of fabric by means of metal bars uniformly distributed over the top surface, Mr. Linton is assuming that the curvature of the net that Eiffel has tested rigid curves of practically every form that the faire might assume, and in no case has the slightest approach to a uniform distribution of pressure been discovered. If, as he suggests, adjust the angle of incidence and, of course, the curvature of the net that keep still long enough to be photographed, by shifting the weight of the metal bars, would involve an infinite number of trials thus reducing his plan to the "cut-and-try" process which he so scornfully in the first paragraph of his letter. Eiffel has proved although Mr. Linton is not aware of it, that from 65 per cent to 90 per cent of the total lift is due to the reaction of the air on the top surface of the wing. How will the irregular ridges on the top of the upper surface of the wing be removed? And, since an actual rigid wing must have several inches of thickness, how will Mr. Linton determine the correct curvature of the upper surface? If he makes the upper surface parallel to the predetermined lower, will he not lose the two in a single stroke? Does he know that two wing sections in all respects identical save that one has a sharp entering edge and the other a well rounded entering edge, will give very different values of  $K_A$  and  $K_{A_2}$ , and different locations of the center of pressure?

As a matter of fact, if Mr. Linton were superficially informed on actual aeroplane development, he would know that his idea of flexible fabric wings has already been out and tried. The same monoplane employs wings of flexible fabric, entirely made by the use of any sort, and perfectly free to assume any curve impressed on it by conditions of speed and load. At the last international meet at Vienna, June 23rd to 30th, 1912, a German machine of this type, equipped with a 40 horse power Gnome motor and piloted by its designer, flew very well, and with several minor problems. But, in spite of the fact that it was lighter than the average one-place monoplane, the best speed it could make was only 40 miles per hour. A single place machine are a great many other monoplane, equipped with the same motor, of the same horse-power, of generally heavier construction, and using rigid, empirically designed wings, that are easily capable of speeds from 50 per cent to 100 per cent faster, no further comment on the enormous difference in efficiency of rigid and flexible wing surfaces is necessary.

# The First Triple-Turreted Warship

A New Italian Battleship Marks a Departure From Existing Types

By Percival A. Hulam

**T**HE triple-turreted warship is now an accomplished fact. The Italian battleship *Dante Alighieri*, and the Austrian battleship *"Viribus Unitis"*, both equipped on this system, have successfully completed their trials. In both cases it is reported that the three-gun turret gave every satisfaction as regards both the mounting and the rapidity of fire. A long-discussed question is thus definitely answered.

The distinction of being the first warship with three guns in a turret to pass into commission belongs to the Italian vessel. The *"Dante Alighieri"* was laid down at Castellamare on June 6th, 1909, launched on August 20th, 1910—she was the first all-big-gun ship to be launched by a Mediterranean power—and was commissioned in the middle of August. She is 320 feet long on the water line and 87½ feet in beam, her hulls being therefore considerably finer than those of the majority of modern battleships. This is largely due to the fact that Italy is more or less combining

guns (14-inch) arranged on the principle of the *"Viribus Unitis"*, save that the superposed turrets will contain two guns instead of three, giving an end-on fire of five, and a broadside fire of ten. In the *"Pensylvania"* there will be three 14-inch guns in each of the four turrets.

The protection of the Italian ship shows plainly in what direction sacrifices have been made to secure high speed and a powerful armament on a small displacement. The main belt is only 9½ inches thick, and even this thickness is not maintained over the whole length of the citadel. The main belt is roughly terminated at the outside funnels, and the bases of the end turrets are protected by only 7 inches of armor. The barbettes, or gun-houses, are protected by only 6 inches of armor, and the hoods over the guns are half an inch thicker. Here again it is interesting to recall the case of the *"Nevada"*, which have a uniform belt of 13½ inches including the whole of the vital parts, while

bined broadside of forty 12-inch guns, while the first four Italian ships will total 87½-ton.

## Wrongly Named Substances

**B**LACK lead does not contain a single particle of black lead, being composed of graphite.

Brazilian grass does not come from Brazil, or even grow there, nor is it grass at all. It is manufactured from strips of palm leaf (*Oleaserosa serotina*) and is imported chiefly from Cuba.

Burgundy pitch is not pitch, nor is it manufactured in, or imported from Burgundy. The best is a resinous substance prepared from common frankincense and brought from Hamburg, but by far the greater quantity is a mixture of palm oil and rosin.

Cuttle bone is not bone, but a structure of pure chalk, once embodied loosely in all the substance of certain extinct species of cuttlefish. It is enclosed in a membranous sac with the body of the fish, and drops

Displacement, 19,400 tons. Speed, 24 knots. Armor: Belt 9½ inches, turrets 9½ inches. Armament: Twelve 12-inch guns, twenty 4.7-inch guns. Coal Supply, 3,600 tons.

Italian battleship *"Dante Alighieri."*

the battleship and the battle-cruiser in her newest ships. Indeed, no distinction is officially drawn between the two principal classes of armored vessels in the Italian fleet, ships of both types—battleships and cruisers—being known collectively as *"navi da battaglia."*

As a result, speeds are unusually high. Italian designs have for many years past produced fast and heavily armed vessels on comparatively small displacements, but only at the expense of armor, and also, it is believed, of structural strength.

The *"Dante Alighieri"* has a displacement of 19,400 tons, and for her main armament she carries twelve 12-inch 45-caliber guns in four center-line turrets. The arrangement of the turrets is rather unusual in four-turreted ships, one being placed fore and one aft, and two close together amidships. The disposition may fitly be compared with that adopted in the Austrian *"Viribus Unitis"*, which has two superposed turrets fore and aft and with that of the Russian battleships of the *"Glasnost"* class, in which the two interior turrets are arranged on the *Viribus* principle. In the last two cases there is a full broadside and an end-on fire of six guns, while the Italian vessel, though firing twelve guns on the beam, brings only three to bear ahead and astern.

It may be recalled that the United States battleships *"Nevada"* and *"Oklahoma"* will have their big

guns are protected by 12-inch armor and 18 to 19-inch turret faces. The *"Dante Alighieri"* has one protective deck an inch and a half thick, the Austrian ships have two, one of 3 inches and one of 1½ to 2 inches.

The designed speed of the Italian ship was 28 knots, with turbines of 20,000 horse-power. On her trials she is reported to have made 24 knots with "something in hand." Her armament against torpedo-craft comprises twenty 4.7-inch guns, twelve mounted behind 4-inch gunnery on the main deck and eight in small turrets abaft of the 12-gun turrets at either end. Three submerged torpedo-tubes are fitted, the maximum coal capacity is 3,600 tons, and the complement is 900 officers and men.

Three other and larger Italian dreadnoughts are completing outfit—the *"Conte di Cavour," "Leonardo da Vinci,"* and *"Giulio Cesare."* On a displacement of 23,340 tons these ships will carry thirteen 12-inch guns in five center-line turrets. The first, third and fifth will have three guns in each, while the second and fourth will be superposed over the first and fifth, and will contain two guns each. Two similar ships, *"Duilio"* and *"Andrea Doria,"* are building, and two more, to be armed with 14-inch or 16-inch guns, will shortly be laid down. It is interesting to bearing on the difference between contemporary dreadnoughts to notice that the first four French ships of this type will have a main

out when the sea is opened, but it has no connecting waterway with the sea of the cuttlefish.

Galvanized iron is not galvanized. It is simply coated with zinc, and this is done by dipping it in a zinc bath containing murettic acid.

German silver is not silver, but a metallic alloy, which was not even invented by a German. It has been used in China for ages.

Money soap contains no honey, but is one part palm-oil soap and three parts yellow or crude soap, scented. Japan lacquer contains no lac and is made from a kind of tree.

Messerschmitt is a composition of silica, magnesia and water. The name implies petrified sea foam.

Mosaic gold has no connection with Moses or the metallic gold. It is an alloy of copper and zinc, used in the ancient medimim or compass-work.

Mother of pearl is the inner of several coats of shells, but not the real mother of pearl, rather being the matrix of pearl.

Pen means a feather (*Latin penna*). A ship's pen is a ship's pen.

Field oil is not oil at all, but for cleaning machines.

Whalebone does not possess any of the properties of bone, but is a substance attached to the upper jaw of the whale and serves as a support for the lower jaw, which is made up of many small bones.

# Safety-match Cough Lozenges

By John Fain

**CHLORATE** of potash is a favorite ingredient in "cough" lozenges, and when made up with a little sugar it forms a very palatable and effective confection. But it is not generally known that one of these lozenges if rubbed on the lighting surface of a safety match box will take fire and burn. The use of lozenges sold by druggists, however, contains too little sugar to work well, and some are composed of pure chlorate and will not work at all. But it is easy to make a lozenge or tablet that will give startling results.

Take two ounces of chlorate of potash and one ounce of white sugar and grind them carefully to a very fine powder. If you attempt to grind them after they are mixed, you may get into trouble. Mix the two dry powders thoroughly and moisten them with a little water or syrup so that they may be worked into a stiff dough. Sprinkle some dry and finely powdered chlorate on a smooth board, so as to prevent the dough from sticking to it, and roll the dough into a thin cake, about the thickness of an ordinary lozenge. This cake may then be cut into tablets with a knife or into round lozenges by means of a cutter. A tin tube, with the edge filed sharp, sawers well. I use a gun-punch. Dry the lozenges thoroughly, this is essential and takes time as the drying must be done at a moderate temperature, if placed in an ordinary oven, they may take fire.

One of these lozenges rubbed against the active surface of a safety match box will take fire and burn furiously, to the great surprise of those who perhaps at the very time are dissolving one of them in the mouth. But be careful not to hold the lozenge in your bare fingers when you rub it or you may get a very severe burn. It may be grasped between the folds of a piece of stiff card board, but a better plan is to take a small wooden board, 4 by 2 inches, and in it, with a center-bit, bore a hole to a depth a little more than half the thickness of the lozenge, so that when the latter is placed in the hole it will rise a little above the surface of the board, or the lozenge, while rubbed, may be held in place by four tacks or small nails driven into the board so far that they will stick up just about half the thickness of the lozenge.

Having placed the lozenge in the hole or between the tacks, rub it with the safety match lighting surface, and it will immediately burst into flame. It may be used to light a cigar, lamp or candle.

There is no danger in this experiment if ordinary care be used. I have exhibited it many times in public and dining rooms, and it always excites great surprise. But like all other experiments of the kind it should be well tried in some out-of-the-way place before an attempt is made to exhibit it even to a private audience.

## Dry Batteries and How to Make Them

By Omega

**TO** construct a good working, small dry cell, procure some pieces of ordinary sheet roofing zinc, six inches wide and seven inches long, bend them around a piece of iron gas pipe, to form a cell six inches high. Cut a circular piece of zinc so as to fit one end, and this will form the bottom of the cell, which must be fitted and soldered after the lapped joint has been soldered.

may be required, say three or four, with a brass terminal attached. These rods or plates can be obtained at almost any electrical supply store, with their tops, to which the binding screw is attached, already steeped in varnish. The object of this varnish treatment is to prevent the creeping of the saline solution, thus preventing the corrosion of the brass binding screw.

Prepare the following mixture: Pebble or crushed carbon and carbon dust, 3½ pounds, white wood or willow sawdust, ¼ pound, black oxide of manganese, 1½ pounds, granulated chloride of ammonium, 1½ pounds.

From a piece of stout blotting paper cut circular or

Fig. 1.—Arrangement of the dissecting apparatus.

Fig. 2.—Simple form of microtome.

square pieces to fit the bottom of the cells, also pieces to form linings for the inside, so as to completely cover the zinc element. Previous to inserting these make up a solution of either nitrate of mercury or bichloride of mercury, in either case one ounce of the salt to one quart of hot water. If the bichloride of mercury is used, add one ounce of chloride of ammonium (sal ammoniac). The addition of the salt will aid considerably the dissolving of the bichloride. As soon as this solution has become cold fill one of the zinc cells to the top with a portion in the corners of a few seconds the inside of the cell will become covered with a thin gray coating of mercury. Only a few seconds time is necessary for this operation. Treat all the cells alike by pouring the liquid from one cell to another, and when the operation is completed, the spare liquid may be returned to the stock solution and kept for future use. Drain each cell, then insert the blotting paper linings, pour a small quantity of the

pitch from a dissolved small sawdust, or iron scale, upon the top of the carboard, then place the pitch and carboard with the pointed end of a metal mesh shaver made red hot, or a piece of iron rod ½ inch in diameter, so as to form a vein. The cell may now be brushed all over with asphaltum varnish, and when this coating is dry each cell should be covered with a single wrapping of stout brown paper and a cover of the same material for the bottom also.

The object of the sawdust is to retain and hold in suspension the saline exuding liquid while the covering of the joints inside with asphaltum varnish prevents the mercury solution from attacking the soldered joints. The amalgamating of the zinc surface with mercury augments the electrostatic force of the cell and insures a longer life. Plain zinc may be used, but it is not so effective as when amalgamated. The black oxide of manganese acts as a depolarizer. Carbon plates or rods that have been used in exhausted dry cells can be used in making up more cells, because the quality of the carbon has not deteriorated while being already provided with a connecting screw a little cut in making up the new cell will be saved.

## Hints for Young Microscopists

By Norman Barden

**WE** do not think that the microscope just to see an object enlarged, but more often to see the structure of that object with its details. Sometimes it is the details of some pathological specimen, of some insect or possibly of one of the infusoria. Each of the specimens named would require a different mode of preparation to obtain the best results, but there is a general plan of operation that is possible and it is to be described. It is true that coarse and large specimens may be placed under the microscope on the end of a needle or held with the forceps, but ordinarily there must be some degree of preparation to show the interior structure. Most tissues of insects will have to be preserved in some preservative after they have been dissected. The mounting media used has a great deal to do with the appearance of the specimen under the microscope. If the refracting power of the mounting media is the same as that of the specimen the object cannot be seen at all. Hence, we must guard against using the wrong media for mounting everything, as we shall see later.

Generally speaking, there are two methods of preparing objects for microscopic investigation: 1. Mechanically by picking and teasing for the separation of cells and isolation of elementary parts. 2. Chemically, by the use of reagents to dissolve false connective tissue, and to act differently on different elements.

There is a host of instruments manufactured for dissecting, but by practice the same can be accomplished with a few simple instruments. This does not apply to the cutting of sections, which as everyone knows, is done best with the microtome. However, about four scalpels, two forceps, one sharp pointed and the other blunt, and a pair of small scissors are to be included in every complete set of microscopic accessories. The dissecting needles are the most accessible of all the instruments and can be made by mounting long fine needles in wooden handles. Some are to be left sharp pointed while others should be given a cutting edge of about an eighth of an inch. Among the other instruments for dissecting there should be a glass pin or tray about four by five inches, a round

Plate 1.—Implantation of lead.

If desired the coil may be made square, in which case a block of wood planed smooth all over, with the corners slightly rounded, may be used. The block should be made 3¼ inches square, so that the sheet of zinc must be cut 6 by 5¼ inches. This size will give about ½ of an inch gap. The treading will take up about ¼ inch. When the joint has been soldered, and the bottom inserted and soldered, a brass terminal or a piece of insulated copper wire must be soldered to the top of the zinc. The length of the soldered joint and the soldered part around the bottom must be brushed over the inside with asphaltum varnish, and the top of the zinc must be brushed with the same.

Prepare the number of carbon rods or plates that

Plate 2.—Section of tongue.

carbon manganese mixture into one cell, place on this a carbon rod, pack in more of this mixture, and press it down with a piece of wood. As soon as the cell is one third full, pour upon this a mixture of sal ammoniac, 6 ounces, dissolved in a quart of water. As soon as the liquid has become absorbed continue to fill the cell with the carbon mixture until two thirds full. Pour into this some more of the sal ammoniac solution, add all the cell with the carbon mixture until within half an inch of the top. Cut a piece of card board ½ inch of the top with a hole in the center so as to pass over the carbon rod, and seal this card in its place with the varnish. Fill all the cells in this manner, and pour some melted

Plate 3.—Bare papillae of the tongue.

Plate 4.—Section of a vine stem.

Plate 5.—Maxillary palpi of tongue of house fly.

strong magnifying glass and a stand for holding it and the glass tray. A convenient way of arranging the apparatus is shown in Fig. 1.

To prepare the specimen for treading, place a very small piece of it in water and pick it to pieces with the sharp pointed needles. This is easily accomplished if the specimen has been macerated for a few days in some chemical preservative. The preservative will dissolve the fats and loosen the connective tissues. The treading must be performed slowly and accurately. Be generous after a great many times because they give up too soon or they sit in a strained position which causes them to become nervous and consequently their arms

Simple Patent Law ; Patent Office News ; Notes on Trademarks

## A Coal Engine

By the Paris Correspondent of the Scientific American

THE internal combustion engine invented by Mr. Archibald Low, a prominent English engineer, is attracting much attention among engineers owing to its novel method of working. In fact, it is operated by a direct feed of coal so as to contain the gas-producer in very compact shape directly within the engine itself and without increasing the size of the engine appreciably. The inventor has been working for a number of years upon the subject, and now brings out a practical running engine of 50 to 100 horse-power, such as our engravings show. The first started with a small 2 horse-power engine in order to prove the principle of the direct coal feed and after this had been run with good success he started building the large engine which is now running in London.

Our diagram illustrates the principal details of the engine, and it works in the following way. Tubes with worms convey ore running in them are used to take up the coal in the depending on the dimensions of the engine and to pass it along within the engine in order to subject the coal to heat within the tubes. In this way the set of tubes act as a gas-producer, and the gas then goes to the engine cylinder to be used on the internal combustion principle. On its way through the tubes the coal is first heated by the exhaust gases of the engine passing around the outside of the tubes, and this heat serves to drive off most of the coal gas, at least, where bituminous coal is used. The carbon and the tarry products then pass along the tube until they reach the part which runs through the combustion chamber of the engine cylinder where the combustion is taking place, and here they are still further heated and reach a high temperature. Steam and air are then injected through the tubes and upon the hot coal, and when this impinges on the hot oil carbon it produces water gas as well as air gas. Referring to the diagram, the coal is fed in through the hopper *A*, and the conveyors *C* draw it along through the set of tubes, the worms being driven by suitable gears. The coal is first heated where the tubes pass through the chamber *B*; as here the exhaust gases of the engine play around the tubes. When in the combustion chamber of the engine *F* the heating effect keeps up and the temperature is still higher. The gases from the coal are given off from the tubes by small openings which allow them to pass into the collecting chamber *D*, and from here they pass to the inlet of the engine for use on the gas engine principle. In order to produce the combustion gas in the proper way, air and steam are admitted to the chamber *U* which also serves as the ash box so that the suction strokes of the engine cause the air and steam to be drawn over the incandescent, and this produces air gas and water gas. When using bituminous coal, which is a very good fuel for this work, the coal gas which the coal gives off in the first place as we mentioned above, is added to the other gases, so that as soon as the coal gas is formed and the gas cock opened a mixture of coal gas, water gas and air gas is drawn into the engine cylinder along with the needed supply of extra air. This forms the explosive mixture for the engine and it is ignited and used on the ordinary internal combustion method. The present single cylinder is 18 inches to 25 inches. The engine is noteworthy for its small size and compact build, and it is self-contained in spite of the fact that it produces its own gas from

Combustion head of engine from hopper side, showing gas tubes and conveyors.

A new internal combustion engine of 50 to 100 horse-power now in operation.

Diagram of the coal engine

Low engine (with inventor). The engine is seen from the ash-chest side.

coal. Thus the new engine appears to be a remarkable one in many respects. The construction of the engine does not need any special care. Starting up is done in ten minutes with the first engine, and this time will no doubt be reduced. In starting, the engine is simply run on coal gas from the mains or by oil, and the change-over to the usual working is done by using a two-way cock at the proper time. No excessive wear is noticed upon the coal tubes, which is another good point. Of oil engines in this connection, especially the Diesel engine, the inventor remarks that however good the oil engine may be in itself, we should be sure that in the future extension in this field there will be a sufficient supply of oil fuel to be had. This point appears to have been overlooked, at least as far as England is concerned. Should the steam engine be put out of the field by its growing competitor, the oil engine, this becomes a leading question, and it is well known that the amount of oil in England produced from shale is comparatively small. In fact, the Admiralty admits that should the navy use oil exclusively for engines, the demand would be greater than the supply, and this regardless of expense at least as far as government work is concerned. Should liquid fuel be used for only one thousandth part of the power production in that country, the home supply would fall far short of what is needed. Without referring to importations of oil, and in time of war this might become impossible, it will be seen at any rate that the question is an important one for England as well as for many other countries. On the contrary, the new engine, should it become widely used, would employ coal which is so abundantly produced in that region. It is to be remarked that the engine is very economical to run, as the inventor states that it consumes only half a pound of coal per B. H. P. hour. The engine runs well even on slack which costs £15 a ton, which means that as a fuel it is about twice times cheaper than oil.

The striking efficiency of the new engine is mainly due to the fact that it uses waste heat. Large gas engines are at a disadvantage, as the heat of the explosion cannot be absorbed as it should be by the piston which moves at a relatively slow rate. But in the new method the heat is utilized by increasing the surface of the combustion chamber, that is by inserting the producer tubes. Hardly any other change is needed beyond adding the compact parts for the gas production, so that the engine has much the usual appearance. The present engine runs at the standard rate of 140 revolutions per minute, and is found to give very satisfactory results as to the quality of the explosion being of very even running and even more so as used on coal gas. At the start, when changing over from coal gas to the normal run, the engine appears to run easier when using its own produced gas, owing no doubt to the quality of the mixture or the gas which is employed. The engine can be run at a high temperature without loss of preignition, and the water in the jacket could even be boiled and the steam used without any danger. Since the saved by the absence of a producer and the engine need be no larger on this account, so that it appears to be well adapted for marine work.

Convention of the International Union for the Protection of Industrial Property

THE convention at the International Union for the Protection of Industrial Property, which was held in London in 1883, is now being held in Paris in 1900.

**RECENTLY PATENTED INVENTIONS**

These columns are open to all persons. The devices are described by special arrangement with the inventors. Those on application to the Advertising Department of the Scientific American.

**Concerning to Approve.**

**TIE BOLLER.**—J. H. BOLLER, 126 De Kalb Ave., Brooklyn, N. Y. This tie boller is adapted to be firmly held in position upon the inside of a collar, to hold the collar in place. The invention affords a free riding surface for a sliding tie in the wide portion between the collar and the neck, but at the same time the tie is held in the neck by the collar. The invention permits the tie to be readily drawn about in the wide portion between the collar and the neck, but at the same time will keep the tie away from the lower outer edge.

**Electrical Device.**

**TELEPHONE ATTACHMENT.**—A. BOSTON, San, Dodge Neb. This invention relates to improvements in telephone attachments, and has particular reference to device of this character derived for the purpose of detecting a very simple and highly effective manner the interference with party lines due to unauthorized parties listening to a conversation.

**WHINICATOR SYSTEM.**—J. L. LORAN, 501 Federal Bldg., Chicago Ill. The more particular purpose here is to provide an electrically operated automatic device, a mobile drum provided with characters which may be seen from a distance the drum being in the hands of the operator, but at the same time desired action at the will of a distant operator.

**Of Interest to Farmers.**

**BALM TIE.**—J. H. FRANK, Westford, Tex. Address Franks Standard Buckle Co., Westford Tex. This buckle is for use in securing the ends of a bale tie such as used on cotton bales and the like and the present invention relates to a construction including a swinging latch for the open end of the buckle. Mr. Franks has invented another and the object of the improvement here is to devise in a simple and practical manner several formal objectionable features by cutting the buckle in such manner as to give the side member when strain comes upon the band, and thereby produce an efficient and advantageous form of tie.

**PLANT CANN REAPER AND GRASS REAPER.**—T. LARSEN, Lakeland, Fla. The invention here is to provide a mechanism having adjustable cutting devices and an adjust the deflecting device in the direction of the support yieldingly by the main frame and capable of adjustment on the main frame.

**Of General Interest.**

**SMITH TANK.**—J. H. SMITH, 1000 S. 10th St., Minneapolis, Minn. This invention relates to a system of a water disposal, the tank being to provide a means for the construction of the tank itself whereby the system as a whole may be readily and quickly installed and its capacity either before or after installation readily adjusted to suit existing conditions.

**MAX EXTRACTING APPARATUS.**—W. S. WATSON, Rock No. 1 Butler Pa. The device is particularly applicable to extraction of wax from the candle plant. An object of the invention is to provide a device in which the process of extraction may be carried on continuously the candle being placed in at one end and being taken out from the other while the wax is taken out at a different place.

**COMBINED MATCH BOX AND BURNER MATCH RECEIVER.**—J. H. BURNETT, 212 St. St., Richmond Va. Mr. Burnett has devised a pocket receptacle for burnt matches which forms an improvement on the burner. The receptacle is arranged directly

below, the bottom of the receptacle (J. H. Burnett), and the receptacle is arranged directly below the burner box and is adapted to receive burnt matches, together with various other impurities from the burner, and the receptacle is adapted to be removed from the burner box.

**FOUNTAIN CORKER.**—J. H. DUNN, 1011 10th St., New York, N. Y. This invention is for corking the hair or reserving draught from the main, in which the container is removable from the corker and is adapted to be used in such a way that the flow of liquid is controlled by pressure applied to the container, the liquid is distributed evenly to the surface of the mouth of the cork.

**BOAT REPAIRING DEVICE.**—J. J. POSE, 1011 10th St., New York, N. Y. This invention is for repairing a boat, in which the device is adapted to be used in such a way that the flow of liquid is controlled by pressure applied to the container, the liquid is distributed evenly to the surface of the mouth of the cork.

**PORTABLE DITCH DAM.**—A. C. CALDWELL, San, CHE. Neb. This invention is an improvement in portable ditch dams and has for its object the provision of a simple, inexpensive, easily operated dam for use especially in first cutting ditches for taking a specified amount of water from the ditch regardless of the amount of water passing through the ditch.

**FORWARDING RAIL HOIST AND WHEEL SUPPORT.**—J. H. NISBET, 1000 S. 10th St., Minneapolis, Minn. This invention provides a mechanism for moving a car or truck from a siding to the upper track of a window and to move therefrom and elements attachable to the side of the window, which the upper track and relatively to which the cars are carried on the upper track are movable whereby the upper track may be lowered to any extent and sustained in lowered position.

**CORN PLATE POOL LAYERS.**—J. D. LORAN, 501 Federal Bldg., Chicago Ill. This invention relates to means for damming or containing the flow of water and has particular reference to means adapted for retaining water in the flow of water, which the dam is adapted to be used in such a way that the flow of water is controlled by pressure applied to the dam.

**FLUID JOINT.**—J. A. KIRCHER, care of Universal Metal Plate Co., Ltd., Box 801 Hamden, Conn. This invention is a device for joining two plates of metal, in which the device is adapted to be used in such a way that the flow of water is controlled by pressure applied to the dam.

**LAWN MOWER.**—J. H. SMITH, 1000 S. 10th St., Minneapolis, Minn. This invention relates to a system of a water disposal, the tank being to provide a means for the construction of the tank itself whereby the system as a whole may be readily and quickly installed and its capacity either before or after installation readily adjusted to suit existing conditions.

**MAX EXTRACTING APPARATUS.**—W. S. WATSON, Rock No. 1 Butler Pa. The device is particularly applicable to extraction of wax from the candle plant. An object of the invention is to provide a device in which the process of extraction may be carried on continuously the candle being placed in at one end and being taken out from the other while the wax is taken out at a different place.

**COMBINED MATCH BOX AND BURNER MATCH RECEIVER.**—J. H. BURNETT, 212 St. St., Richmond Va. Mr. Burnett has devised a pocket receptacle for burnt matches which forms an improvement on the burner. The receptacle is arranged directly below, the bottom of the receptacle (J. H. Burnett), and the receptacle is arranged directly below the burner box and is adapted to receive burnt matches, together with various other impurities from the burner, and the receptacle is adapted to be removed from the burner box.

**FOUNTAIN CORKER.**—J. H. DUNN, 1011 10th St., New York, N. Y. This invention is for corking the hair or reserving draught from the main, in which the container is removable from the corker and is adapted to be used in such a way that the flow of liquid is controlled by pressure applied to the container, the liquid is distributed evenly to the surface of the mouth of the cork.

**BOAT REPAIRING DEVICE.**—J. J. POSE, 1011 10th St., New York, N. Y. This invention is for repairing a boat, in which the device is adapted to be used in such a way that the flow of liquid is controlled by pressure applied to the container, the liquid is distributed evenly to the surface of the mouth of the cork.

**PORTABLE DITCH DAM.**—A. C. CALDWELL, San, CHE. Neb. This invention is an improvement in portable ditch dams and has for its object the provision of a simple, inexpensive, easily operated dam for use especially in first cutting ditches for taking a specified amount of water from the ditch regardless of the amount of water passing through the ditch.

**FORWARDING RAIL HOIST AND WHEEL SUPPORT.**—J. H. NISBET, 1000 S. 10th St., Minneapolis, Minn. This invention provides a mechanism for moving a car or truck from a siding to the upper track of a window and to move therefrom and elements attachable to the side of the window, which the upper track and relatively to which the cars are carried on the upper track are movable whereby the upper track may be lowered to any extent and sustained in lowered position.

**OIL BURNER.**—C. F. FOWLER, 817 N. 10th St., Minneapolis, Minn. This device burns kerosene in a fractured shell with equal facility. The burner is adapted to be constructed and provided with a heat retaining portion which the burner is adapted to be used in such a way that the flow of liquid is controlled by pressure applied to the container, the liquid is distributed evenly to the surface of the mouth of the cork.

**CLOCK WINDING DEVICE.**—C. F. FOWLER, 817 N. 10th St., Minneapolis, Minn. This device is an improvement in clock winding devices and has for its object the provision of a simple, inexpensive, easily operated device for winding a clock.

CLOCK WINDING DEVICE

**FLUID JOINT.**—J. A. KIRCHER, care of Universal Metal Plate Co., Ltd., Box 801 Hamden, Conn. This invention is a device for joining two plates of metal, in which the device is adapted to be used in such a way that the flow of water is controlled by pressure applied to the dam.

**KNITTING MACHINE ATTACHMENT.**—W. S. WATSON, Rock No. 1 Butler Pa. The device is particularly applicable to extraction of wax from the candle plant. An object of the invention is to provide a device in which the process of extraction may be carried on continuously the candle being placed in at one end and being taken out from the other while the wax is taken out at a different place.

**MAX EXTRACTING APPARATUS.**—W. S. WATSON, Rock No. 1 Butler Pa. The device is particularly applicable to extraction of wax from the candle plant. An object of the invention is to provide a device in which the process of extraction may be carried on continuously the candle being placed in at one end and being taken out from the other while the wax is taken out at a different place.

**COMBINED MATCH BOX AND BURNER MATCH RECEIVER.**—J. H. BURNETT, 212 St. St., Richmond Va. Mr. Burnett has devised a pocket receptacle for burnt matches which forms an improvement on the burner. The receptacle is arranged directly below, the bottom of the receptacle (J. H. Burnett), and the receptacle is arranged directly below the burner box and is adapted to receive burnt matches, together with various other impurities from the burner, and the receptacle is adapted to be removed from the burner box.

**FOUNTAIN CORKER.**—J. H. DUNN, 1011 10th St., New York, N. Y. This invention is for corking the hair or reserving draught from the main, in which the container is removable from the corker and is adapted to be used in such a way that the flow of liquid is controlled by pressure applied to the container, the liquid is distributed evenly to the surface of the mouth of the cork.

**BOAT REPAIRING DEVICE.**—J. J. POSE, 1011 10th St., New York, N. Y. This invention is for repairing a boat, in which the device is adapted to be used in such a way that the flow of liquid is controlled by pressure applied to the container, the liquid is distributed evenly to the surface of the mouth of the cork.

## Twenty-five millions of dollars

To this extent the American people have set the seal of approval upon the 1913 Cadillac

This evinces such an overwhelming preference in favor of a single high type of motor car as against any one of more than two hundred other makes that it practically obviates the opportunity for comparison.

It means that more than twelve thousand motor car buyers after a critical analysis have recognized that the elements vitally essential to a real motor car are the dominant characteristics of the Cadillac.

It means that more than twelve thousand motor car buyers after a critical analysis have recognized in the Cadillac:—

- A car that is *manufactured* and not merely an assembly of components.
- A car whose maker is one of reputation and of stability.
- A car whose parts are thoroughly standardized and thoroughly interchangeable.
- A car of unsurpassed mechanical accuracy.
- A car of dependability and of durability.
- A car possessing a factor of safety so liberal that it withstands far more than should reasonably be expected of any car.
- A car of luxury, a car of comfort, a car of convenience.
- A car of elegance and of refinement.
- A car of simple and of easy operation.
- A car of minimum depreciation and of maximum value as a used product.
- A car with which there is obtainable a real "service," both from the maker and from the dealer.
- A car which offers the maximum of efficient service for the maximum time at the minimum cost.
- A car which is "different" and which by reason of the "differences" commands a position uniquely its own.
- A car whose merit is not confined to one or a limited few "talking points," but rather a car of super-excellence in its entirety.
- A car which will uphold in abundant measure the wisdom of those who have honored it with their seals of approval.
- A car whose distinctive characteristics are obtainable only in the Cadillac itself.

UNITED STATES TIRES ARE GOOD TIRES

They eat down tree bolls.

## Just what kind of a tire do you want?

Pick out the features you want to find in the tires you buy. You want generous mileage, full rated size flexibility, protection against rim cutting, ease of manipulation and security of fastening.

Measure up this deal tire against every other tire on the market and then compare with a United States Tire.

You will find United States Tires combine all these identical features of your tire in a way that no other tire on the market approaches.

Some of the set res have been greatly strengthened at one or two points—some at others.

But as a matter of general comment among dealers, car owners and car manufacturers, that never has any to combined *all* these special points of superiority.

as to

# United States Tires

In the matter of mileage—he most accurate shareholder has United States Tire today's dividend on an average of 25 to 50 cents a share, though it was a year or so ago that it was as high as 75 cents a share. The company has been making a big profit for some time. The United States Tire Company has been making a big profit for some time. The United States Tire Company has been making a big profit for some time.

This is the first and only one that has ever been absolutely guaranteed against recycling. It is by law added to the most expensive and to the most difficult to take off yet it can possibly come off the machine if you are ready to take it off. In fact if you were to have a tie hole in your shirt it would be difficult for you to specify a single dress as less useful than you can't get today in a United States Treasury.

If this is the kind of a tire that you want to use United States Tires ought to be the exclusive equipment on your car this season. They are made in Plain, Chain and Nobby treads and in three styles of fastening, including the famous Dunlop (straight side).

Cost no more than you are asked to pay for other kinds

United States Tire Company  
New York

While the subjects already named are most directly useful in engineering the benefits of a more general education must not be overlooked. Engineering is a learned profession, and its members must of necessity be well versed in a great variety of knowledge. In general and specifically he is charged with the practical application of natural science. Beyond that his relations with other men are such that a knowledge of logic and law are very helpful. He should be a good accountant and be familiar with the use of indexes and files.

There has been much discussion about the possibility of becoming an engineer without a college education. Some men have done so. A remarkable athlete can win a contest with a handicap but most of us are glad to win with all the advantages possible. No better answer can be given.

**Convention of the International  
Union for the Protection of  
Industrial Property**

(Continued from page 434.)

On June 2nd, 1911 has been ratified (signed) by the following governments: Austria (Hungary), Belgium, Brazil, Bulgaria, Canada, Denmark, France, Great Britain, Greece, Italy, Japan, Mexico, Norway, Netherlands, Portugal, Switzerland, and Russia. It will be recalled that Article 18 of the convention provides that the ratification of the convention shall be deposited with the Department of State at Washington not later than April 1st, 1911; and that the convention shall be put into execution among the ratifying countries on the day when the Treaty of Commerce with the final protocol replaces the ratifications of the countries which have ratified it. The convention of Paris March 29th 1883 the final protocol annexed to it, and the Convention of London of the 10th 1904 relating to the location of the International Bureau of the Additional Act of Brussels December 14th, 1900 These acts cited shall remain binding on the countries which have ratified the Convention of Washington convention of 1911.

The ratifications of the countries mentioned having been now deposited in the Department of State, there are still remaining five governments adherent to the prior conventions which have not yet ratified the Washington convention. These countries are Belgium, Brasil, Cuba, Denmark, Sweden.

It is officially declared that the ratification for Austria-Hungary is effective with respect to Bosnia and Herzegovina and the ratification of Great Britain relates only to the United Kingdom of Great Britain and Ireland.

At the conference of Washington twenty nations other than those already mentioned were invited to participate in the deliberations with a view to becoming adherents to the Paris treaty of 1898 and its subsequent amendments. Up to the present time only six have responded positively. These are the United States, Belgium, Canada, Cuba, Haiti and the Dominican Republic.

# EVERY CAR OWNER NEEDS THIS BOOK

It makes you intimately familiar with every electrical device on your car or motor boat. Tells you how to avoid electrical trouble, how to locate it and how to correct it. Written by experts in such simple terms that any one can understand it.

The only book ever written that covers every phase of electric installation on automobiles and motor boats. Write today for a copy before the edition is exhausted.

**The Packard Electric Co.**  
Dept. 10  
Warren, Ohio

there is a large field of objects that will be found interesting. For the infusoria a wide mouthed bottle will be found quite sufficient. A conical net of muslin or linen will be needed for securing other animals that swim about in the different strata of water. To collect the infusoria get some of the small weeds that grow on the bottom of a small ditch or pond. No doubt there will be some of the tree like colonies of the volvox fast on to the weeds. You may also find other specimens of the rotifers and other polyps. The volvox are to be looked for on the small green branches of the weeds and sometimes can be recognized with the naked eye. A collection of this sort can be kept in a small aquarium for several days. For securing the free swimming animals the net is swept through the water and then drained. Now it is carefully turned inside out and the bottom gently rinsed in a wide mouthed bottle half filled with water. Also a lot may be lowered inverted into the water and at the right depth turned up right. This method of obtaining the animals will give a great variety of specimens of all kinds including some kinds of bacteria. So we see that a small pond or ditch will afford nearly all the objects that are of interest to the beginner. As for getting plant stems and vegetable epiphytes, the summer garden will have a good variety. Turn up all of the plants and vines that have ribbed stalks (cylindrical beautiful cell structure). Filices and ferns are easily caught with a box net and should be soaked for a few days in a five to ten per cent solution of formalin hydrochloride before examining. Some vascular plants contain minute worms which can be easily mounted. For the beginner the collection and preservation of objects will be found to be very interesting and will no doubt lead to the studying of other micro organisms that are not found in stagnant water.

## Description of Plates

- Plate 1—Implication of hair in skin. Local staining. Balsam mounting. X 50.
- Plate 2—Section of the tongue. Methyl violet staining. Balsam mounting. X 25.
- Plate 3—Section of the tongue showing the fine papillae. In alcohol. X 100.
- Plate 4—Section of skin showing the animal cell structure. Glycerin media. X 25.
- Plate 5—Maxillary pulp of the tongue of the house fly. Balsam mounting. In alcohol. Treatment with potassium hydroxide. X 40.

## Engineering in the Alps

WORK is going on at present upon a tunnel through the mountains between France and Switzerland in order to give a more direct railroad connection. What is remarkable in this case is that unusually large quantities of water were met with and the piping which had been laid in the tunnel was not sufficient to take care of the great outflow from the underground springs. As the tunnel was flooded up to two feet high and quite a large cascade flowed out at the entrance. This also caused the neighbor ing springs to fall more or less. The somewhat curious result follows that an out put of 100 to 200 gallons per second will be taken away from the lands of the Rhone or the French region and is now to be added to the Rhine basin in the Swiss region and thence to German territory. Owing to this unforeseen event the expense of the work will be increased to a great extent and the cost of the tunnel reckoned at first at \$3,000,000, will now be at least tripled. It is stated that but little previous work was done in the way of geological surveying and this is now regretted. In fact, the accident occurred exactly at the point predicted by M. Fourcade, president of geology at the University, according to his examination of the geological conditions of the

Are you between the upper and nether mill stones?

THAT'S where many a business finds itself today. Cost of production and selling on the increase. Competition grinding down prices. And in between, somewhere, the net profits.

## Multigraph System to the Rescue

Put brains into the hopper and let the stones grind your difficulties into profits. The man with a Multigraph has a daily inspiration to new saving ideas and the quickest way to carry them out.

With real typewritten letters he gets into towns his salesmen can't reach, follows up inquiries promptly and thoroughly, locates and sells good prospects.

And the same machine produces the printed features that he needs, too. Booklets, folders, enclosures—always something new and interesting to his trade.

It's real print up—better than the average job printer's—and costs 25% to 75% less.

This handy little machine—which takes up no more room than a typewriter desk—has revolutionized many a business.

# —and now the gear lever is gone!

## Gear control on steering wheel enables one to select any speed by merely moving the thumb

The trend of automobile invention is rapidly toward EASE OF OPERATION. You saw the quick detachable rim replaced by the demountable. You saw the slow, old "one-at-a-time" method of lighting give way to the dash-board switch. You saw the starting crank thrown into the junk pile—replaced by the magic starter button.

Now comes ANOTHER revolutionary advance—the mightiest of all—gear shifting accomplished by the mere movement of the thumb. For the gear control is on the steering wheel. Compare the ordinary gear-shift where the driver leans over and yanks at a lever with might and main—perhaps 100 times a day—with this new "thumb-operated" Gear-Shift. Now you drive without moving your body, without taking your eyes off the road, like the expert pianist performs without looking at the keyboard.

Think what this means—no more reaching for levers, no more levers to take up space. And safety—safety to driver and occupants, safety to passing motorists and pedestrians, safety to you (a).

The beginner or the most timid woman now handles the biggest gas car without fear or difficulty.

Miss Alice Adams of Los Angeles

## The GRAY Pneumatic Gear-Shift

### Approved by Experts

The practicability of the Gray Pneumatic Gear-Shift has been rigorously proved.

It has had countless factory tests.

And we have analyzed every conceivable road test. One car carrying 40 passengers was driven 25,000 miles without repair of gear shift. Being used for illustration purposes, the gears on this particular car have been shifted ten to twenty times as often as they will ever shift your gears.

One user is a girl of 16. She handles her father's 40 Horsepower Touring Car with the ease of a veteran. Two hundred expert drivers have operated the Gray Pneumatic Gear-Shift and they to a man approve it.

Nine leading automobile makers recently witnessed an actual performance. As a result, the Gray Pneumatic Gear-Shift will be found on thousands of leading 1914 cars.

### "Anticipating" Your Speeds

You may be ascending a hill at high speed and at the same time indicate "second." The very instant you hit the speed incline you go into "second" by depressing your clutch pedal.

Or, in a busy street, when the advance signal is given, a quick depression of clutch pedal engages first gear. The next moment you are under way "second" again. Take it on your new, 1914 car, instruct the agent, from whom you buy, to have the maker put on the Gray Pneumatic Gear-Shift.

The emergency brake is attached to the service brake pedal, which is locked when desired. Thus the brake lever as well as gear lever is discarded.

By merely removing the air valve inside the car is securely locked preventing theft.

### Also a Self-Starter

While we term it a Pneumatic Gear-Shift this is a self-starter, too—a dependable self-starter, the only successful one we know which can be applied to a complicated car. This starter is the post star "high speed" type, the kind that revolves the motor rapidly and in sure, a quick, sure start. Operated by a push button.

With this pneumatic equipment one can shift gears, start the car, jack up the car, inflate tires, clean the car and lock it.

### The Price

Our price, though it varies according to the car to be equipped, is very reasonable.

Nor does it cost much to install the apparatus. Any man who can afford a motor car, CAN afford to be without the GRAY Pneumatic Gear-Shift.

### Goes on Any Car

To equip your car with the Gray Pneumatic Gear-Shift, go to your garage dealer. He will not only get it for you but he will also put it on in short order.

To get it on your new, 1914 car, instruct the agent, from whom you buy, to have the maker put on the Gray Pneumatic Gear-Shift.

The Gray Pneumatic Gear-Shift. The only car with the lock and key for the steering wheel.

## How It Works

FIRST—Set the indicator on the wheel for first speed. Then make one full stroke of clutch pedal. This accomplishes (a) The disengagement of the clutch. (b) The automatic stopping of the transmission shaft. (c) The automatic movement of all gears to neutral position immediately upon the stoppage of the transmission shaft. (d) The opening of the air valve that forces the selected gear into engagement. The return stroke of the pedal engages the clutch and starts car.

SECOND—The indicator is then placed for "second speed" and the clutch pedal depressed, where upon the same operations take place as indicated for first speed.

THIRD—While in second speed indicate "third," and again make a complete stroke of the clutch pedal. (The four speed control can be had if wanted). A lock latch on the indicator obviates the danger of selecting the reverse gear when car is moving forward.

Before passing from one speed to another the gears assume neutral position.

## Correspondence Invited

Leading 1914 Cars will carry this Equipment.

We will be glad to write you a detailed explanation of the Gray Pneumatic Gear-Shift to quote you prices, and to tell you where and how you can get this wonderful equipment. Send your communication by letter, postal or coupon below. If you write today, you will get a reply by return mail.

and to disseminate the results of scientific research.

## Rothamsted Up to Date

**T**HIRTY-sixty years ago, Sir John Lubbock and Gilbert White, the names of Rothamsted familiar to agriculturists, the world over and may there be hardly a look on agriculturists in this the results of hardy on that famous experimental farm are not more or less frequently mentioned. Since the death of Lubbock in 1900 and that of Gilbert in 1901, the work has gone on without interruption and in fact has grown to expanded dimensions. In 1928, the farm was granted a grant from the British government. The history of the enterprise is traced in the last annual report of the director.

John Lubbock came into possession of the Rothamsted estate in 1843 and at the time began experiments with various manure substances, first with plants in pots and then in the field. In 1844 he obtained the services of Joseph Henry Curtis as director and began more systematic field experiments.

The Rothamsted Experimental Station has always been independent of any other institution and was maintained out of the cost of the late Sir John Lubbock during his lifetime. In 1880 it constituted a trust for the continuance of the work, setting apart for that purpose the laboratory (which was built by public subscription and presented to him in 1865), certain areas of land on which the experimental plots were situated and £100,000. The management is entrusted to a committee comprising four representatives of the Royal Society, two of the Royal Agricultural Society, one of the Chemical Society, one of the Linnean Society and the owner of Rothamsted estate.

In 1901 Sir J. F. Mason, M.P., presented the committee with a £100,000 fund, the income of which was devoted to his successors. In 1907 the Goldsmiths Company made a grant of £10,000 the income of which is devoted exclusively to the investigation of the soil. The Linnæan Society has also made a grant of £20,000 toward the endowment. In 1901 there was organized a Society for Extending the Rothamsted Experiments, which has since that time made annual subscriptions toward the undertaking. Finally in 1911 the Board of Agriculture of the British Government announced a plan whereby funds are granted to a certain number of institutions carrying on fundamental research in agriculture, each being dedicated to a particular kind of research. Rothamsted was selected as the institution for investigation of the soil and plant nutrition problems and received an annual grant of £2,000. (Certain agricultural scholarships have also been instituted, the income of which carry on their work at Rothamsted.)

The farm has recently been enlarged by the addition of 230 acres of land, on a seventy-seven year lease, with the aid of a grant of £5,000 from the government and a like amount from the Society for Extending the Rothamsted Experiments.

The most remarkable feature of the work at this institution is the continuity of observations made on the same experimental plots over a long term of years. In the words of the director, "Nowhere else in the world do such data exist for studying the effects of seasons and manuring upon the yield and quality of the crop and for watching the progressive changes that are going on in the soil."

The illustration of the value of these long series of observations is the way in which ordinary wheat and experience has led to the importance of crop-rotation has been re-emphasized. Wheat was grown on the same plots

for sixty-two consecutive years, and the crop yielded at the end of that time only about one fourth as much per acre as wheat grown on similar land for fifty-two years as a part of a four-course rotation. In both cases the land was not fertilized.

## The Cholera Granary

**C**OCIDENTALISM held (theoretically at least) that cleanliness is next to Godliness. Among Orientals, on the other hand, it would seem better to be dirty and holy, than to have clean hands but an impure heart. And toward this habit of contamination of personal and religious purity has been taken by the appointment of a commission to inquire into the sanitation of Hindu and Mahometan pilgrimages centers. Here is no doubt a most delicate undertaking, since religious ideas may be involved which the Oriental is likely to adhere to with absolutely unreasoning fanaticism. One need but recall how carriage grained with filth, which the Mejer was fanatically expected to extract with their teeth, precipitated the Mutiny, the Calcutta Black Hole and the rest to realize how filthy might prove the task of grafting Occidental sanitation upon Oriental civilization. And yet the cholera and like "scourges of Allah" are not every few years to endanger Europe and the Western World. Cholera granaries, from which such pestilence are supplied must be cleaned out and closed up.

Though cholera does not disappear entirely in winter its essential bacterium loses much of its virulence during hibernation; the disease is not fairly active until spring, when it is likely to appear, for example, as the Asiatic plague. And by what route does this visitor travel to its destination? One of two from Mecca to the Mediterranean countries—Greece, the Adriatic, Italy, Morocco, Northern Africa, and by way of Egypt, the Suez, the Red Sea, the Persian Gulf, the Indian Ocean, the Bay of Bengal, the Andaman Islands, and westward to Vienna, St. Petersburg, the Baltic and to Berlin and the ports whence transatlantic vessels sail. Mecca has since Mahomet been in some sort a secondary cholera depot. It is an epic reflection of history that India Mahomet's legend was made in the winter rather than in the hot season, millions of human lives would not thereafter have ended prematurely. Immense suffering and stupendous material loss would not have come to pass. As for Mother India has through countless generations fed her children the cholera, the typhoid, the dysentery, the malaria, and absorbed it while they have sought to purify their souls in that ghastly stream. Thence have the Asiatic Mamelukes, thus saturated with the cholera virus, been making their pilgrimages Meccawards, and from Mecca, or caravan or through the Red Sea, by land and latterly by steam, and now also by the Hedges Railroad. It is this railway which especially makes Occidental sanitarians anxious, because it is a much speedier route than by caravan or water, and may get the pilgrim passengers to Mecca during the incubation period of the disease, when it may pass unrecognized.

Most of those pilgrims have been and are absolute fanatics, and neither know nor care about sanitary precautions—in the obvious which no "meat is to be acquired" (to use Kipling's superb phrase in "Kim") so those pilgrims have through the centuries been visiting the Prophet's shrine and have bathed, when they could in the Holy Wells (it is now forbidden) in order to reach the very cradle of holiness and thus have become a cholera granary subsidiary only to India. Then European and African Mahometans, just as devout and every whit as fanatic as their Asiatic brethren make their pilgrimages into Arabian deserts, and are accompanied by thousands of their fellow worshippers in the Holy City, have in their own home-coming distributed the dreadful infection to Northern Africa, to Egypt, to Syria and the Mediterranean countries.

## Time and the Sciences

**T**IME and space enter into all our perceptions, and therefore into all our scientific observations and reasoning. But not always in the same way, nor with the same emphasis. The biologist of the old school may have been content to collect specimens and to describe them all this without reference, or explanation, or interpretation. A very different attitude is taken by the modern biologist, who enters his interest about problems relating to the development or evolution of the individual and the species—a phenomenon into which the element of time enters very clearly.

Again, it may be said to say that ninety five per cent of all published work on chemistry makes no reference to time, and this in spite of the fact that the manufacturing chemist is most vitally interested in the time required for the completion of his reactions. This seeming neglect, which has of course been remedied in the case of physical chemistry, is due to the fact that largely to the fact that many reactions proceed with considerable speed, so that the time element, with

important, takes very of itself, as it were, when all other matters have been being attended to.

In physical chemistry and physics time plays of course an important and well-understood role. But even here there is a limitation. The question is usually "How long?" or "How fast?" Rarely does the physicist ask "When?" In other words, he is interested in intervals of time, but not ordinarily in concrete points of time. This distinguishes the physicist from the biologist, sciences, that they do inquire, not merely after the duration or speed of events, but after their date also. The historical sciences, *per se*, are geology and astronomy. Geology is a very special science, devoted to the unraveling of the past history of our planet. As yet it is almost wholly qualitative. The geologist can tell us the order of sequence of events in the past, but as to the length of the periods involved, he is only beginning to obtain crude estimates. With the future he is not, as a rule, averily concerned.

So the astronomer we look for the most accurate and most extensive instruction in questions relating to time. He is our court of final appeal when we require an accurate standard unit of time. He studies not only the paths and velocities of the heavenly bodies, not only the history of the earth, but the earth with great accuracy coming events. Astronomy is one of the oldest and one of the most highly developed sciences. Its field is the universe, its period the reign of time.

## Crossing the Ocean in a Flying Machine

**S**OME day the Atlantic Ocean will be crossed by a flying machine—of that those who have followed the development of the aeroplane from its feeble beginnings in 1903 to the present day have fully convinced. Lord Northcliffe's generous offer of a \$200,000 prize for the achievement will bring that day necessarily nearer than may be suspected, even though it does nothing more than to arouse a world-wide interest in the performance of one of the most difficult technical achievements that still remain unfilled.

When Lord Northcliffe made his announcement, sober-minded engineers naturally asked: What are the difficulties in the way? Can the prize be won? If so, how soon will it be won?

As we look back at Wellman's attempt to cross the Atlantic in a dirigible, which was admirably designed and which was by far the best craft of its type built in America up to that time, we are inevitably forced to the conclusion that such poultryarian experimenting must be done before a heavier than air machine can be sent out on its venturesome transatlantic journey with some hope of success. It would be astonishing indeed if considerably more than the amount of Lord Northcliffe's prize were not expended in these preliminary studies. But even granting that by winning the prize the successful contestant would merely recoup himself, he must inevitably have developed the art so markedly that his craft will have commercial possibilities far greater than those which it is now. If we are to attempt to cross the Atlantic in a dirigible, which was admirably designed and which was by far the best craft of its type built in America up to that time, we are inevitably forced to the conclusion that such poultryarian experimenting must be done before a heavier than air machine can be sent out on its venturesome transatlantic journey with some hope of success. It would be astonishing indeed if considerably more than the amount of Lord Northcliffe's prize were not expended in these preliminary studies. But even granting that by winning the prize the successful contestant would merely recoup himself, he must inevitably have developed the art so markedly that his craft will have commercial possibilities far greater than those which it is now.

If we are to attempt to cross the Atlantic in a dirigible, which was admirably designed and which was by far the best craft of its type built in America up to that time, we are inevitably forced to the conclusion that such poultryarian experimenting must be done before a heavier than air machine can be sent out on its venturesome transatlantic journey with some hope of success. It would be astonishing indeed if considerably more than the amount of Lord Northcliffe's prize were not expended in these preliminary studies. But even granting that by winning the prize the successful contestant would merely recoup himself, he must inevitably have developed the art so markedly that his craft will have commercial possibilities far greater than those which it is now.

Because present motors cannot absolutely be relied upon, but are a consideration of the possibility of slipping upon a rough sea and succumbing from great ocean waves, which has not yet been solved. But the remarkable performance of the hydro-aeroplane at the recent Monaco meeting prove that the solution of this problem is not far off. Several machines ran out of the harbor into the white-capped Mediterranean and in the teeth of a gale. All but one successfully rose from the surface, rose to Reims, a point some miles down the coast, and alighted again, a new record. What is more, Godard's performance in alighting and holding his own in a gale by means of a drag, shows what can be done on the high seas even in a storm.

To be sure, these machines were comparatively light, the heaviest weighing only 3,000 pounds. But the meeting proved conclusively that the machine of the future will not be helpless in heavy seas. In our opinion a flying boat of the Currier type is likely to be even more successful than the Godard type which figured at Monaco. In other words, a boat type in which such that, two powerful engines, an aeroplane, and at least two, perhaps three, men from a small boat, can be used with great safety and more power than any other device.

# Engineering

**Construction of the "Britannic"**—It is reported that the "Britannic," which is now being built by Harland & Wolff, will be 357 feet in length, 64 feet 6 inches in breadth, with a gross tonnage of between 50,000 and 55,000. Although shorter and narrower than the "Aquitania" and the "Britannic," will, according to these figures, be short four thousand tons heavier and will even exceed the "Imperator" in tonnage. The "Britannic," which, according to the original plans, was to be launched next March, will probably be ready to take the water by the end of November of this year.

**A Plant with a 5,413-hp Head**—Work has begun on a hydro-electric power plant in Switzerland, which will have a water head of 5,412 feet. The water is to be taken from the lake of Fully near Marignay in Canton Valais. What such a head means, we may appreciate when considering that the pipe line will have to be constructed to withstand a pressure of 2,426 pounds per square inch at the lower end. The line will be about 234 miles long and the pipe will be from 19 1/16 to 26 5/8 inches in diameter inside, while the thickness will vary from 1 1/16 to 1 3/16 inches. The upper section will be of the well-known lap-welded type, while the pipes of the lower part will be of the butt-welded type. The turbines will be of 15,000 horse-power. The plant is being constructed after the plans of Mr. Bouché of Lausanne.

**Clath Plates**—In place of rawhide or paper for noiseless, shock-absorbing gearing, cloth or cotton fiber plates are now being used with great satisfaction. The cloth is piled up between steel strands, subjected to a hydraulic pressure of several tons per square inch and laid in compression by threaded studs passing through both strands and filler. The teeth are then cut. The plate is as strong as cast iron. The teeth are elastic enough to come to a good bearing across the full width of the face. They are not affected by atmospheric changes and are not damaged by contact with oil. In fact they are soaked in oil to exclude moisture and furnish constant lubrication. Such gears have been designed for transmitting from 1/6 to 150 horse-power.

**Machinery Exhibits at the Panama-Pacific Exposition**—Rapid progress is being made in the construction of the main exhibit buildings at the Panama-Pacific International Exposition at San Francisco. There will be fourteen main exhibit buildings. Work upon the Machinery Building, the largest of the exhibit group, was begun early in the year and it will be ready for the complete installation of exhibits by the opening date, August 20th, 1918. The Machinery Building will have nearly eight acres of floor space. There will also be an auxiliary structure to be known as the Gas and Fuel Building. Electrical machinery, instead of being placed in a separate building, will be located in the Machinery Building and classed under the general heading of machinery. All parts of the building will be served by adequate crane facilities. Electric current, alternating and direct, gas and water, will be available in any portion of the building, compressed air and steam will be provided in a section adjacent to the Gas and Fuel Building. General illumination is to be provided by the exposition company, but a nominal charge will be made to exhibitors for other utilities service they desire. Special rates for power will be made to exhibitors who use it to show machinery in motion. The floor of the Machinery Building is designed for a load of two hundred pounds per square foot. No charge will be made for exhibit space.

**Prema Coal Shaft**—It was not until 1883, when Postach invented the "breasting method," that Holland's coal fields became of any practical value. The coal is found in the province of Limburg, and, what is more, the two main runs Kerkstra and the Kerkstra, the very first coal mines operated in continental Europe in medieval times. When, after 1850, the mining industry came to be more seriously considered, and several concessions had been given out by the Dutch government, it was found that the coal lies very close to the surface, and, in places, comes in the two medial layers near Kerkstra, where a coal is encountered immediately under the solid rock, there is a stream of drift and that contains great quantities of water. This condition of things made it practically impossible to mine the shafts, which had to be of considerable depth for the coal layers are encountered at a depth of from 300 to 1,000 feet. The breasting method, however, has successfully solved the problem, and Holland now has a flourishing mining industry. On the spot where the shaft is to be dug, from 35 to 40 inches of water is driven down the shaft to the solid rock in a shaft 5 feet larger in diameter than the projected shaft. Pipes are then sunk into these horizons, and through them is circulated, by powerful forcing machines, a chemical solution soaked down to the coal. The solution is then driven up the shaft, and, as the water is driven up, so is the rock. After the breasting machine has been working day and night for two months, the hole from openings of sand, a shaft is then driven down from bottom to top with strong cables, and the coal is then driven up the shaft with the breasting machine.

# Electricity

**Wireless Ambulances**—During the four months following December 15th, 1917, when the act to regulate radio-communication went into effect, 3,407 licenses have been granted to wireless operators and stations in the United States. Of these 1,185 were granted to amateurs, and 985 amateur stations have been licensed.

**Street-car Ambulances**—In our use of April 5th we described the street-car ambulance built in this country for use in Bahia, Brazil. One of our readers has called our attention to a one designed and built after the plans of Dr. Hosmer, when Health Commissioner of St. Louis, in 1904. Service by this car was inaugurated in December, 1904. Evidently Bahia cannot claim to be the first city to employ an ambulance of this description.

**Electric Searchlight for Airships**—According to recent information, electric searchlights operated by storage batteries are to be mounted on all the military airships in Germany. An arrangement similar to that employed on warships will allow two airships to communicate with each other. The luminous searchlight storage batteries will be mounted in the forward nacelle. Thus equipped it is believed that airships may be employed for nocturnal attacks.

**Free Removal of Tungsten Lamps**—We are informed that the manufacturers of tungsten incandescent lamps have decided to reduce the price of lamps to half their present value. A number of the large Edison companies are anxious to place tungsten lamps on the free removal basis. It is considered probable that the opportunity to do so will be afforded by the reduction in the price of the lamps. It is possible that the tungsten lamps are so hard-going as the carbon filament lamp, with which it is even now a serious competitor.

**Ones and Five Trees**—What is the reason that pine and fir trees, and others of the spruce, are surrounded, more than other trees, by ozone, and that therefore forests of the "needle-leaved" type are so health-giving? If the theory of Prof. Lemstrom, of Helsinki, is correct, this can now be explained, for the "needles" act on the atmosphere as generators of electricity, so that the trees are always surrounded by electricity and consequently the atmosphere is electrically charged. Prof. Lemstrom began his study in this direction by studying the use of the spikes or "boards" of grain (wheat and rye) which he found to be generators of electricity which the plant requires for its proper development.

**Are Waves Spark Waves**—The recent radio-telegraphic tests conducted by the Marconi Company at Arlington station have demonstrated that waves produced by the electric arc are less modified by absorption than waves produced by spark apparatus. Up to a distance of about one hundred miles there was very little difference between the two types of waves. It was possible for the Arlington station to talk to the "Belen" at a distance of 2,100 miles. But as the distance was increased over two thousand miles, it was found that the waves produced by the electric arc showed a relatively increasing efficiency and possessed an energy much greater than those from the spark apparatus.

**Cadmium Vapor Lamps**—The mercury vapor lamp would be ideal were it not so deficient in red rays. It has been found that by operating the lamp at much higher temperatures in a quartz tube there is an increase in the emission of red rays as compared with green and blue rays. It is possible that such emission can be obtained, but does not possess enough red for ordinary commercial purposes. Efforts have been made to find a vapor which will give the desired spectrum. However, the desired end has now apparently been reached by Dr. Wolf, who has found that in the lamp the temperature of the gas is raised, but this is corrected by adding a small amount of mercury. It is stated that a lamp of 3,000 candle-power uses 620 watts.

**Meters on the Back Porch**—The railroad town of Bannock, in the Empire State, has the very convenient scheme of placing electric-light meters on the back porches of the houses. In fact, most of the houses are provided with porches on the back porch to receive the electric meter. The advantage of this arrangement is that it permits the meter reader to read a great many meters at one time. It is a convenience for the meter reader, but it is also a convenience for the consumer. It is due to the fact that the consumer very seldom reads his meter, so that he is surprised at the end of the month if his bill is larger than usual, whereas if he had watched the meter day by day he might have been able to determine the cause of the sudden increase in the amount of electricity consumed by realizing that on the previous night the lights were burned unusually late or a stormy afternoon made it necessary to turn on the light earlier than usual. Probably the principal advantage to the consumer of this arrangement is that his house need not be entered by the meter reader every month.

# Aeronautics

**A 500-mile, Non-stop, Cross-country Flight**—On May 1st aviator Eugene Gilbert, on a Morane monoplane, made a non-stop flight of 513 miles from Paris to Vittoria, Spain. After refueling and refilling his tanks, Gilbert continued for some distance, but finally descended at Medina del Campo, where he broke some of the guys of his monoplane in making a bad landing. The time of this flight was 8 1/2 hours, which is the record for a non-stop cross-country flight.

**A Thousand Miles Across Country in 22 Hours**—After a close call from death because of pneumonia, Ernest François Guillaux, a young Frenchman famous for his many flights over Paris, made a trip to Biarritz in his Clermont-Bayard monoplane. Leaving Biarritz at 6:22 A. M. on April 27th, he flew, with a few stops, flew to Bordeaux and thence to Villanueva, where he made a second stop for replenishment and continued on his flight. He descended the third time in Kullum, Holland, before dawn on the following day, having covered over 1,000 miles in less than 24 hours.

**A Record Flight from Paris to Berlin**—In the competition for the Pommeroy Cup for the longest flight across country in a single day, Pierre Ducasot, on a 50 horse-power Borel monoplane, covered the 555 miles between Paris and Berlin in 8 hours and 44 minutes flying time, or at an average speed of 64 miles an hour. The start was made at 1:50 A. M. at Longjumeau, 211 miles away, was reached in 2 1/4 hours or at an average speed of nearly 85 miles per hour. About 60 miles per hour was averaged from Langen to Hanover, Germany, and 50 miles per hour from Hanover to Berlin. As stops some two hours in length were made at Liege and Hanover, the total elapsed time of the flight was around 13 hours, which is excellent when one considers that Ducasot required two days in which to make this flight last August. This twice aviator, on a Morane monoplane, left Villanueva by Biarritz, where he was met by Ducasot in an attempt to beat the French pilot. He covered the 130 miles to Madrid at 87 miles per hour and returning the flight, crossed the Ardennes at a height of 11,000 feet, and finally landed at Wanne, in Westphalia, at 11:30 A. M. after a total flying time of 13 hours and 44 minutes throughout the last 90 miles. The time he abandoned the flight because the wind still continued.

**The First Flight Across the Isthmus**—After a well-attended attempt to fly across the Isthmus of Panama by several aviators, it remained for Robert H. Fowler, the second man to attempt the crossing, to make the first American attempt to accomplish the difficult 40-mile flight. Fowler arrived at Panama on April 11th with an 80 horse-power Gago hydro-aeroplane and a cinematograph and man to operate it. The next day he made a 14 hour flight above Panama and took moving pictures of the city. After flying over the city he landed at Colon. Mr. Fowler and his crew in the second of two flights made on April 25th, Fowler flew across the Isthmus the whole way above the canal two days later. He started at Panama beach at 6:45 A. M. and, after getting to gain altitude at the entrance to the canal, he flew over the city of Colon, encountering a 25-mile breeze at Colon, Fowler continued toward Cristobal, but his motor stopped at the back of gasoline and he landed in shallow water. The pontoon of his hydro-aeroplane was slightly damaged. This flight has been several times attempted by leading aviators, but all gave it up because of no chance of sighting on the way, and also because of the air currents in the Colon Cut.

**Constructing Machines on a Scientific Basis**—The Royal Aircraft Factory in Great Britain undertook last year a series of experiments on full-sized aeroplanes with a view to determining the most efficient design. The experiments were carried out in conjunction with aerodynamic researches at the British National Aerodynamic Laboratory. After calculating the results that would accrue to two different machines in the laboratory, the results were compared with those obtained in the field, and the result was well well remarkable. With a Farnham biplane, fitted with the same horse-power motor as before, an additional load of 82 pounds was carried as against 80 pounds that laboratory calculation showed should be carried. The additional load was 200 lbs. per sq. ft. of wing area, or 17.7 miles per hour to 47.5, an increase in flexibility or speed variation of from 35 to 37 miles per hour to from 33 to 47.5 miles per hour, an increase in load of 10 per cent, an increase in climbing ability of 100 per cent, a very great increase in stability and ease of control, and a very great increase in total efficiency. The improvements in the Government biplane B2 were very marked indeed. Whereas in the Military Aeroplane Competition last fall it was supposed to maintain an air speed of over 55 miles an hour, to climb at a rate of 200 feet per minute, to fly fully loaded for three hours, to glide at an angle of 1 in 6, to be capable of landing at 40 miles per hour, and to have a range of speed of 15 miles per hour, the results actually obtained were 72 miles per hour, 480 feet per minute, 8 hours, 1 in 6, 40 miles per hour, and 32 miles per hour respectively.

Stairway for use of the blind, guided rail in the center for ascent and descent

Section of fire escape and stairway leading to roof playground and running track.

Blind men in the bowling alley find the play an excellent form of pastime.

### Training the Sightless

By Walter L. Beasley

THE New York Association for the Blind in the completion and opening of its new building 111 East Fifty ninth Street, has produced the most perfect plant for the manual, educational and social training of the blind in America, or probably in the world. The structure is fittingly termed the "Light House" being dedicated for the exclusive benefit and welfare of those who live in eternal night. In fact, the opportunities here offered to enable those who are without sight to conquer darkness by learning practical handicrafts, thereby making them self-supporting as wage earners, mark a new era for the emancipation of the blind, industrially and intellectually. As complete isolation from the world is now recognized as one of the chief terrors of blindness, and blindness without opportunity is the worst kind of slavery, one of the principal objects the new structure is designed to serve, is to give the independent blind men and women an opportunity to be self-helpful, and again to take their place in the work and play of the sighted world.

To teach the blind, therefore, actual accomplishments in various fields of useful work, is the main purpose of the institution. The Light House is a fire-story, modern fireproof building of brick with stone frontages. It represents the last word in interior construction and equipment for the development of the physical welfare of the blind. One of the distinctive building features is a combination fire escape with wide stairways and guide-railings, provided also with open air platform, affording roomy space for tables, chairs, etc. Each floor leads out into one of these open galleries, so that at will any activities can be carried on in the fresh air during the summer months. The architect was Mr. William Wallow Jones. The accompanying illustrations show some of the unique interior and exterior features of the building adapted to meet the requirements and convenience of the blind. The first floor is devoted to a large waiting and assembly room, with a gallery above. This is filled with a beehive of industrial workers, where many looms are operated by the skillful and ingenious blind women. Here various articles of handiwork are turned out. Weaving and the work in basketry have been developed to a high standard. Articles that are made by the blind can stand competition and usually surpass in excel those similar ones made by the seeing white draperies, with as many as six different colors, woven in patterns, are successfully turned out by the "Light House" weavers. There is perhaps distinction in this blind work from the fact that the artisans are all able to execute without supervision, after a reasonable apprenticeship, all the processes required in their industries. The blind girl throws her ball, which sometimes has as many as four hundred threads, prepares her own material, fastens it to her own shuttle,

and weaves the article, including the pattern. The only assistance which she gets is the direction as to what colors she is to use and what design she is to follow. The second floor is an attractive saleroom, where are displayed and sold to the public the various articles made by the blind, such as furniture, carpets, rugs, woven articles, curtains, draperies, cushions, lace, embroidered portfolios, bags, card cases, baskets, etc. In the rear is located the museum, which contains interesting exhibits representing the industrial, educational and pictorial progress of the blind, from the past to the present. The third floor is occupied by the general and special offices, and class rooms for the teaching of adults and children. Here is also located the census and registration room, containing a list of over ten thousand names of the blind in greater New York who have been investigated by the association. This work is in charge of Mr. W. I. Scandlin, who, before losing his vision, was a well known editor and authority on photography. One of the most noteworthy and essential features in the building is the thorough arrangements provided for physical training and

recreation. This it appears is more vital to the sightless than to the seeing. The gymnasium, having an experienced instructor, himself partly blind, is fitted with all the latest apparatus to strengthen their weak bodies and to stimulate their wits. The accompanying illustration shows a typical animated scene on a Saturday afternoon, when a squad of blind boy scouts are doing some of their exercises. The "Light House" scouts were selected by Sir Robert Baden-Powell to be his honor guard at the great rally given to him by the Boy Scouts of America. Probably the crowning feat ure, bringing the greatest appreciation and joy to the young blind people, is a spacious roof garden forming an ideal playground for roller skating, driving, games and dancing in the open air. This also has additional attractions, in fact, a decided innovation in city building, in the shape of a wide, concrete running track. This occupies a half section of the roof, and the sight less runners find much amusement in getting around the track in real sportsmanlike fashion. In the basement there are installed other important features for the development of the physical welfare of the blind, a large swimming pool, numerous baths, and a bowling alley. A bowling club meets weekly, and this exercise is recognized as a most excellent form of pastime for the blind. One of the accompanying pictures shows a detail of a much frequented stairway leading to the basement and the guide railing employed for the person ascending or descending. Sharp angles and corners are avoided, and this same idea is carried out in all stairways, walls, closets, vestibules, etc., to the building.

The New York Association for the Blind is a philanthropic society, supported entirely by voluntary contributions. In the half dozen years of its existence it has accomplished important and far-reaching achievements for the progress of the blind. It secured legislation and the cooperation of health boards, medical associations, etc., for the prevention of blindness. It helped to place the first blind children in the public schools of New York, now there are 100 in attendance. It secured an amendment to the education law, making the education of blind children compulsory, so that they are no longer forced into ignorant and helpless lives, or compelled to become beggars or drudges. It published the first magazine for blind children in this country, *The Searchlight*, printed in Braille. In many other ways it is coping with the problem of blindness and doing continuous helpful and uplifting work in behalf of the blind world. The president of the association is Dr. John H. Finley, with Helen Keller as one of the vice-presidents. Winifred Eliot, the secretary, is especially interested, devoting her time, service and efforts to the welfare of the blind and directing its numerous activities from the "Light House" headquarters. Among the influential members of the practical advisory board is Hon. Thomas P. Gore, the young blind United States Senator from Oklahoma.

# A Journey in a Zeppelin

Impressions of a Trip in the Airship "Viktoria Luise"

By Carl Dienstbach

The multiple-bladed horizontal and vertical rudders.

It is the absolute novelty of the sensation that runs down it impossible to imagine beforehand just how it feels to journey through the air in the ideal comfort and with the safety and speed which characterize a Zeppelin airship.

The sensation is a combination of the distinct impressions, the lightness, complexity and self-sufficiency of this new world of yours, its complete detachment, and finally, its mighty power.

Balloons, aeroplanes, smaller airships, cannot impress one so strongly. Their cramped quarters and moderate dimensions do not suggest such a "world in itself." Their progress is not so certain. They have the jarring and jerking characteristic of earthly locomotion. But in a Zeppelin one feels as if one were on another planet, drifting through space on its prescribed course. One loses the sense of speed, and at times might think himself still hovering in mid air, were it not that the picture below keeps on changing as frequently and quite as softly and smoothly as the floating fancies of a dream.

In the cabin there is complete absence of vibration and noise, for the hum of propellers and motors is as subdued as the rustling of trees and the softest speaking voice is distinctly audible. The motion would suggest the drifting of a spherical balloon were it not that the mind is very quickly impressed by the fact that it is not an aimless. Only when something in this floating panorama below tries to remain, do you realize, with a start, the amount of "brute force" (nearly 500 horse-power) that keeps your dream going. If you see the locomotive of an express train with the piston rods vibrating to and fro, gradually falling behind with its tail of waving handkerchiefs on a truck that keeps pace parallel to your course, you feel a sudden respect for the driving power of the great propellers fore and aft.

Later a flight of pigeons appears at a lower level, also going to the same direction. They hold their own only for a while—until they turn from our course in the cabin the air is not at rest. A beautiful little breeze, just enough to remind you that you are flying, comes in occasional puffs through the windows, but even outside the air is sucked along by the huge hull, and does not blow against the extended hand with a force corresponding to the ship's velocity. But a hurricane sweeps into the exposed front car. The pilot of an aeroplane meeting the "Viktoria Luise" would behold the unusual sight of a man at the helm in the uniform of a naval sailor wearing automobile goggles. Recently a transparent windshield has been fitted to the "bridge." The crew of the big passenger Zeppelin last summer was partly composed of naval sailors and officers being trained to man the huge new airship of the navy. The peculiar character of the cabin, which on each crew from almost every visitor to the shed the simple exclamation, "A dining car," appears only after the airship has ascended. After landing it seems to shrink again into insignificance, but a thousand feet up in the air it feels as roomy and as gorgeous as a palace.

The passengers are housed as in an apartment. The aluminum gangway is folded against the wall, opposite the door through which you pass in entering the ship. In front you see the steward's little pantry, with a door opening into the long passageway to the front car and to the machinery and steering devices.

Looking to your immediate left, you see a magnificent view of the "Viktoria Luise" as it glides along easily with the speed of an express train.

Inspection reveals a double flight of ladder steps fitted against the tube's wall. A short aluminum ladder is also strapped to the side of the passageway that can be locked to the lower end of the tube to complete access to the observation platform (practically a small deck) on top of the hull.

At the rear end of the cabin you pass again through a door to a floor of ribbed aluminum plates. Its right corner serves as a wash room, its left corner is partitioned off for the wireless telegraph. In the center another door opens into the rear passageway—an old low vista, reaching beyond the rear car to the hind most point of the hull, where a man may climb through one of the round, canvas-covered portholes, and out over the frames of the rudders and stabilizing planes to make repairs, a thousand feet above the ground. An engineer is always sent to this porthole shortly after the ship has got under way to inspect the working of the rudders. A narrow path of ribbed aluminum, carried on low steps, forms the floor of the passageway.

In the shed the cabin looks a poor protection against the weather, of the six large windows on each side, the three in the rear are gaping holes. Those in front have such neat and practical panes of cotton that if necessary the rear ones could be at any time equally protected. But when the airship ran into a driving rain there was not a trace of dampness or discomfort in the cabin. Looking through the paneless windows, one might see whole sheets of water blown to the rear but the wide overhang of the hull above and the speed of the ship, never permitted a single gust to blow any

Working the nose of the airship into the shed.

rain toward the windows. To motions acquired in houses or in railroad cars or ships, the airship's cabin seemed protected by magic. It was a pleasure to walk through its length and to think that it was virtually walking on air.

There is so much room that the upholstered wicker chairs seem hidden on the sides and never in the way of people passing each other. It was thrilling to hear a footstep far back in the "hold" hear a door open, and then see an engineer from the rear car, in damp silks, emerge through another door and continue on his way to the front car to report at the "bridge."

There was a coming and going of sailors (aerial apprentices) who complained how nerve-racking the dreadful responsibility made even their short shifts at the "engine" (in an airship there is more than one helm). The strongest sensation after all, was the cruise in cloudland. It was a stormy morning, on the way to the air harbor, heavy showers poured against the windows of the street car. The clouds were hanging low, torn into fantastic and beautiful shapes of thin sheets between black and white. After ascending the airship was directly among them, several times it ran into them, and all became gray outside and a peculiar odor was noticeable. When we entered it was necessary to see the dark masses float by at the level of the ship. But the cabin felt so homelike that any feeling of fear or dizziness was out of the question. Wonderful reassurance was the fact that one had a roof over one's head, even a beautiful mahogany ceiling.

The sunlit landscape, seen from not too great an altitude, and from a swiftly moving observatory was an experience so novel that no comparison will give a true idea of it. It is different from the view from a mountain because most objects are so much nearer, while from a tower or a sky scraper the lower altitude, makes the field of sight comparatively limited. But the determined swift movement of an airship gives the view the same depth as from a high mountain, yet things appear so much more distinct. The result of this and of the entire lack of such experience is a truly bewildering richness of vision, quite beyond the mind's power to grasp. The most familiar scenery appears disguised to beyond recognition. Well known buildings are the most useful clues to identification, then rivers, ditches, ponds and roads. Barely trees, hills, the outlines of towns, slip by little. In an airship one realizes for the first time how little we see in everyday life. Everything is pitifully laid bare, secrets seem striped stark naked. We fly over a village, it is still naked and we pass it quickly. Yet during those few seconds we can make an excellent guess at the fortunes of each inhabitant. We take in all the telltale marks about a stable and learn the number and condition of the stock inside. There is no hiding in a forest, the ground is distinctly visible between the trees and through the branches. If the air is clear enough to see a strong field glass, the same applies to war times and high levels of flight, the one necessary condition being that the line of sight approaches the vertical.

The airship's freedom from any fixed line of travel, except among high mountains, has a very unusual effect. The country through which this trip extended was quite familiar to the visitor yet the airship took him for the first time to two never-visited cities around Frankfurt which were touched on the airship as a matter of course, and just as easily as the

All aboard and ready to cast off

Gliding along easily with the speed of an express train.

other ones where he had been. Even with present high fares, airship travel pays well for the foreign tourist who wants to get acquainted with a country. He sees as much of it in hours as otherwise he could get in weeks.

### The Hydraulic Ram

TO most people an hydraulic ram is a mystery. As a matter of fact, it is the most simple and efficient mechanical device for raising water by means of power which is probably what makes it seem so mysterious to those who have never seen a ram at work.

Pumping water by hydraulic ram makes a water supply system far superior to any other except a gravity system. In some instances it is even better than gravity in matter of expense when a gravity supply requires a long line of pipe. A windmill must depend on the wind, a gasoline engine means continuous attention and expense for fuel, an hydraulic ram costs nothing to operate, requires no attention, depends upon nothing but the source of supply.

Hydraulic rams are not only adaptable for pumping water for household purposes, but they can be used for delivering large quantities of water for irrigation, town water works, railroad tanks, etc. The only advantage which rams may be incurred for pumping water for any of these purposes, there is a naturally a great demand for rams. This applies particularly to irrigation, as it enables the farmer to raise crops at a small cost per acre.

Hydraulic rams can derive the power for operating them from a spring brook, flowing artesian well or river, and if the ram can be located at such a point that a constant stream of water can be supplied to it through a pipe having an incline of fall of three or more feet in a given distance the conditions being such that the power water which escapes at the ram can be drained away, it is possible for the ram to deliver a steady stream of water to a point at an elevation thirty times the difference between the levels of the ram and the water supply. This stream of water, once started flowing, will continue without interruption day and night, winter and summer, requiring no attention nor expense except for the renewal of rubber valves on the ram once every year or two. This is a trifling expense, as the valves cost but little.

The efficiency of a ram can be very great, reaching, under favorable conditions, 80 per cent or more. This means that the ram will pump more water to the mine before than any other kind of engine which pumps water by means of water power.

The amount of water that may be pumped per day by such a ram is remarkable. It will pump as much as a quarter of a million gallons a day. If a delivery of two million gallons a day is required, a "battery" of rams can be installed. That is, two or more rams are placed side by side.

Where pneumatic pressure tanks are used instead of gravity tanks, rams will not only supply the water, but also maintain the air pressure up to 100 pounds, as may be desired.

### The Current Supplement

HOW long has the ocean been in existence? This is a question a difficult question to answer, yet it is possible to make a fairly good estimate of the age of the ocean, as is shown by F. W. Clarke in this week's issue of our SUPPLEMENT—Mr. R. D. Andrews has made a study of the comparative efficiency of Eiffel and American bridges, which he reports in this issue—The new Louisville Railway, which opens this issue, and on which the most powerful electric locomotives of Europe will be in service, is described—E. R. Stone gives a valuable survey of the facts known regarding the propagation of high frequency waves, which he reports in this issue—C. H. Britton discusses the origin of the native American Indians, on the basis of recent investigations in Nigeria—A very striking example of protective mimicry is afforded by the coloration of certain butterflies, as is shown in an excellently illustrated article by the Hon. J. Bennett, M. A.—Mr. Charles H. Clark discusses the cycle of his gear engine.

Extending the Erie Canal to Chicago.—Writing in the current issue of the *National Waterways Magazine*, Representative Cyrus Cline of Indiana, suggests that by canalizing the Maumee River from Toledo to Fort Wayne, a distance of 120 miles, and then cutting through a fairly level country along the shores of Indiana to some point in Lake Michigan, a distance of 120 miles more, the Erie Canal can be extended to Chicago. This would provide a direct waterway of sufficient size to float heavy freight from Chicago to New York and eastern cities without reloading. It would cut off 850 miles from the existing circuitous route by way of Lake Erie and Lake Huron, the Detroit River and Lake Erie. He asserts that the Erie Canal without the assistance of trade by the direct route to Chicago will not carry ten per cent of the freight it is capable of floating.

### A Copper El Dorado in Mid-Africa—The Katanga

By Charles Fitzhugh Talmage

AS the leading copper-producing country of the world the United States may soon have a formidable rival in a region that was a few years ago an unknown and trackless wilderness.

Not long since the SCIENTIFIC AMERICAN called attention to the fact that American map-publishers had not yet discovered the existence of the flourishing German export of Tatanaga, on the China coast, founded about a decade previously as the administrative center of the colony of Katschau. In consequence of our editorial of March 11th, 1913, subsequent editions of American atlases have remedied this particular oversight, without, however, seeming to realize that our criticism applied generally to the amazing "out-of-date-ness" of American, as contrasted with European, productions of this class.

Just as the publication in 1910 of a large-scale map of the China coast minus Tatanaga was an enormity, so the publication in 1912 of a large-scale map of Africa minus the Katanga is a characteristic piece of ineptitude on the part of our competitors. Such a map now lies before us. In conspicuous type it bears the legend "Copyright, 1912," while in an obscure corner, in very inconspicuous type, is the real date of the greater portion of the map, viz., 1906. In view of the latter date it is not surprising to find that the Katanga—whose name has been so conjoined with its mining riches of the world for the last three or four years at least—is still known to the cartographer as "Mide Kingdom." The atlas in which this map appears sells

Sketch map of the Katanga.

Railways built in 1911. Under construction. Several other lines are in contemplation. Mide Kingdom, the capital of the district, is destined to become one of the important railway centers of the western world, already by direct railway communication with Cape Town, 2,800 miles distant. The Katangians show signs in which agricultural studies have recently been carried out by an equal mission, for fifteen dollars. As the geographical works at the disposal of most of our readers may be equally defective, we present herewith an up-to-date map of the Katanga.

The Katanga is the southernmost district of the Belgian Congo. Its area is approximately 150,000 square miles, and its population is estimated at one million. Being mainly a lofty table-land, it enjoys a temperate climate and in this respect appears to be better adapted to colonization by white men than any other part of tropical Africa. It is abundantly watered, and has suitable agricultural resources.

It is, however, the vast mineral wealth of the Katanga that has recently focused the attention of the world upon it, and has already attracted capital to the amount of about \$60,000,000. The natural curiosity is that not only is the Katanga itself on the eye of being intersected by railways, but it is attracting to it the great trunk lines of the continent, and will soon be a clearing-house for the commerce of southern and central Africa.

The latest makeshift way of getting mail shows on the postbagged terminals of Lake Tanganyika on the west, Mombasa, Dar-es-Salaam, and Beira on the east, and Cape Town on the south. From Beira a railway is now rapidly pushing forward, and will probably connect up with the Katanga within a few years. As soon as the latter system extends to the

shows of Lake Tanganyika, it will be in communication by water and over-land with the Congo River, the Indian Ocean, and the Atlantic. The Katanga, however, is not yet connected with the Congo River, and must pass by the Congo River to the south. By the Congo River it is connected to the Congo River, and must pass by the Congo River to the south. By the Congo River it is connected to the Congo River, and must pass by the Congo River to the south.

Thus the time is measurably near at hand when Mide Kingdom, the capital of this flourishing region, will be connected with the Indian Ocean of Africa. This town, which has sprung up over night, and whose population is about 1,200 Europeans and some 10,000 natives, already boasts of numerous comfortable hotels—the principal of which are suitably styled the Oasi and the Carlton—public buildings, clubs, and even sporting pleasure theaters. The value of the buildings erected there last year amounted to \$1,350,000.

While gold, tin and diamonds are all mined in the Katanga, the all-important product of the country is copper. Its potential wealth in this mineral is said to be almost fabulous. According to G. B. Beak, late British vice consul at Mide Kingdom, the southern copper belt extends 200 miles, with a breadth of 50 to 60 miles, i. e., about 7,000 square miles of territory. Quoting from a South African newspaper: "The ore bodies are of enormous size. At one mine a cross-cut at the 100-foot level is 475 miles in length, and for 80 feet or more the ore averages 80 per cent copper. This mine alone is estimated to produce 50,000 tons yearly, even allowing for the losses of 100,000 tons yearly. It is available on the European market at less than \$150 a ton. The road is at last cleared for the full development of the great Belgian Congo copper belt, there now being nothing to prevent the southern portion of the Katanga from becoming another Beak, with Mide Kingdom as a worthy rival to Johannesburg."

The melting problem has been provisionally solved by the shipment of coke from Rhodesia, but coke furnaces are about to be installed in the Katanga.

### Saving the "Latine"

By Ferdinand A. Hylan

THE SCIENTIFIC AMERICAN has already dealt at some length with the attempts to save the valuable cargo of the British frigate "Latine," which was sunk on the coast of Cuba on September 10th, 1912, with ten tons of specie on board. When the vessel was wrecked—only one man being saved—she had in her hold 1,000 bars of gold and 500 bars of silver, of a total value of \$6,000,000, and in the two previous and rather primitive attempts to get at the wreck in 1901 and 1907-8 the divers succeeded in getting up the precious metal to the total value of just over half a million dollars.

For the last two years the National Salvage Association of London has been working on the wreck, and Capt. Gardiner, who is in charge of the operations, has every hope of being able during the coming season to raise enough of the specie to pay the speculators a very handsome profit. The wreck is actually the property of Lloyd's. In the first place, it was claimed by the Dutch government, and a company for its salvage was formed in Holland. In 1923, however, the King of Holland made a gift of the vessel to the King of England (George V.), by whom it was transferred to Lloyd's, who then offered to insure the vessel. The Dutch salvage company still exists and has some sort of claim on whatever may be recovered, while Lloyd's, the present owners, considered salvage totally impossible. The company now engaged on the work is the Dutch salvage company, which is now owned by Lloyd's and another 15 per cent to the Dutch company, retaining 70 per cent for itself.

During 1912 the work was considerably impeded by bad weather, and although the salvage vessel "Lyon" was out for eight months it was only enabled to raise in 270 hours of work as compared with 800 hours in the previous year. Nevertheless, the work that was done was most effective, and Capt. Gardiner is confident that it is the conditions in which the wreck is now, large quantities of the treasure will then be brought to the surface. In July last one of the divers found a fair sized hole in the bottom of the vessel, and, on putting his arm through, was able actually to touch the gold bars and to draw an almost perfect estimate of their size (they are 7 inches long, 3½ inches wide and 1½ inches thick). Unfortunately, owing to the removal of the sand from under the bottom, the vessel had started over on its west side again, the hole being entirely covered.

One of the great difficulties with which the salvagers have had to contend is the strong current which runs over the wreck. The tide runs with a stronger current, and the effect of this is to draw the vessel in a southerly direction. It is now necessary for the divers to work in a southerly direction, and the vessel is now in a southerly position. The vessel is now in a southerly position, and the vessel is now in a southerly position.

## The Maximum Parcel

To the Editor of the SCIENTIFIC AMERICAN

Under Section 15 of the Parcel Post Regulations, if a parcel exceeds "twenty-two inches in length and eight inches in width, it must be refused, no matter how small the excess may be." In another paragraph of this same Section 15 the measuring of "combined girth and length" is explained by saying that "in measuring the length the greatest distance in a straight line between the two ends of the parcel shall be taken, while the girth is the actual measurement by a tape encircling the parcel at its thickest part."

Largest packages of different shapes allowed by Parcel Post regulations.

Under these provisions strictly interpreted a rod 72 inches long would have to be infinitely thin to be accepted, and a perfect cube would have to be not more than fourteen and four tenths inches high, because the girth of such a cube is 4 times 14.4 or 57.6 inches, and its length 14.4 inches to the girth 57.6 makes 72 inches exactly.

The 14.4-inch cube contains  $14.4 \times 14.4 \times 14.4$  or 2,985.984 cubic inches; and the 72-inch rod contains more or no cubic inches; and a question that naturally arises is, have we any firm between the thin rod and the cube that "will enable the shipper to send a still greater number of cubic inches under the rule?"

In a recreational problem the square cross section is the most advantageous, so that the problem may be stated in the following form: What should be the dimensions of a rod or wire which contained girth and length 72 inches, under the rule that such rod shall contain the greatest amount of cubic inches, and how many cubic inches will it contain?

Let  $x$  inches be the width and thickness of this bar, so that its girth will be  $4x$  inches. Its length under the rule will be  $(72 - 4x)$  inches. The cross sectional area is  $x^2$  square inches and the volume  $V$  is  $x^2 (72 - 4x)$  cubic inches. We may therefore write

$$72x^2 - 4x^3 = V$$

and note that  $V$  should be as large as possible or a maximum.

Differentiating for the maximum we have

$$144x - 12x^2 = 0 \quad 47/4x = 0$$

whence

$$x = 12$$

We, therefore, have girth, or  $4x$ , equals 48 inches, length, or  $(72 - 4x)$ , equals 24 inches, cross section, or  $x^2$ , equals 144 square inches, volume, or  $72x^2$ , equals 2,985.984 cubic inches.

This represents a gain of approximately 3,456 - 2,986, or 470 cubic inches, which amounts to nearly 16 per cent, and the package has the advantage of being of a form that is much more conveniently handled than the cube.

The dimensions of this package to recapitulate are 12 inches by 12 inches by 24 inches. It is represented in the annexed rapid perspective, where the combined girth and length is the full length of the string  $A, B, C, D, E, F, G$  and  $H$ .

A cylinder of the same length, 24 inches, and, therefore, of the same girth, 48 inches, would have a diameter of 48/π or 15.28 inches, and a volume of almost exactly 4,400 cubic inches.

The volume of all solids is known to be the one that incloses the greatest volume within a given superficial area, but the largest sphere that could be sent through the mails has a diameter  $d$  equal to  $72 / (\pi + 1)$ , or 17.38 inches, with a volume  $V$  equal to  $1/6$  of  $\pi d^3$ , or 2,760 cubic inches. Under Parcel Post Regulations, therefore, the spherical form of package which can only be considered as a matter of curiosity, is even less advantageous than the cubical.

A point not to be overlooked is that in any case the weight limit of eleven pounds must not be exceeded.

ARTINGTON, Va.

JOSEPH DICKMAN.

## The Levee Question

To the Editor of the SCIENTIFIC AMERICAN

About twenty years ago, on the occasion of examinations of old Mississippi River pilots on the question of whether a piece of land was an accretion or island, I took advantage of the opportunity to discuss with them the question whether the levees were on or below the bottom of the river. It was their opinion that they raised the bottom and would eventually cause the bottom to be higher than the land at the sides. It seems to me that if the levees increased the current to the extent that the water carried with it the silt, it would be a mass of mud before reaching New Orleans. The theory of opening up through headlands and allowing a straight course to the sea as a panacea has an objection in that it would cause such a current that the river in its course would pick up much more silt on account of its force. Should such a course be pursued, the river would probably be un navigable on account of the current then, also, the effect of such a current against a bank would be disastrous. Should not the river be allowed to follow its natural course, spreading out over and encroaching and raising the level of the land along its borders on certain occasions? Would it not be better to leave to the land according to the laws of nature and not to struggle ineffectually against them?

The question of leveeing, when near me the years I lived in the Mississippi Valley raised the legal question in my mind as to whether the levees could be legally built, in view of the fact that they changed the natural course of the flow and raised the water of other land, and at the time the question of whether or not the building of levees on the Arkansas side of the river, raising the flood level in Tennessee, would not be stopped by injunction issued in the Federal Court.

MOBILE, Ala.

GEORGE H. CYRUS, JR.

## Forth and Clyde Battleship Canal

To the Editor of the SCIENTIFIC AMERICAN

With reference to the notice of the above project in your issue of March 26th last, permit me to point out through your correspondence columns, that the British government has promised to aid in the project on certain conditions. (See page 1 of the accompanying report of the engineer's lecture to the Royal Scottish Society of Arts on January 31st, 1910.) The altered strategical conditions under which the home battle squadrons of the British fleet are now placed have rendered the construction of the ship canal an imperative necessity, and the question is now mainly one of terms between the treasury and the canal promoters. I would further point out that the ship canal would be of the utmost commercial importance to the maritime trade passing between the West Indies and north central Europe.

MALCOLM CAMPBELL L. ANDERSON BARRIE, Edinburgh, Scotland.

...to begin, the "Lytton" lying in about the position. The wreck lies between the islands of Vancouver and Vancouver Island, and is in the island strait surrounding the latter sea, and the effect of the deep channel is to give rise to a strong current from the latter sea into the North Sea, and vice versa, with the result that the channel is kept comparatively clear by currents that run at from 8 to 7 knots. Over 1,000,000 tons of sand was removed in this way, the effect of which has been to increase the depth of water over the wreck from 14 feet to 30 feet. The vessel now lies on a hard clay bottom—no hard, indeed, that a 4-ton gun lying on it has not been able to sink in at all, while a 6-horse-power drill was unable to penetrate more than three feet. The matter was last dealt with in the SCIENTIFIC AMERICAN a description was given of a novel device invented by Mr. Simon W. Lake, of Bridgeport, Conn., which had been brought to the notice of the admiralty in view of its facilities for dealing with wrecks. It may be described as a long, flexible tube, in which divers would be able to work for a much longer time than usual, and in greater comfort. While there is no doubt that this arrangement would be of considerable value in less troubled waters it is impossible to use it in connection with the "Lytton," as the strong currents that have to be contended with, as well as the heavy swell which runs in from the North Sea.

The principal difficulty remaining to be dealt with is presented by the enormous masses of rusted steel and ballast in which the vessel is encased. It must be remembered that the vessel has been lying at the bottom of the sea for 115 years, and that when the bars were taken on board they were placed in the shot rooms under the ammunition, which has become rusted together. During the operation of 1907-8 a diver found a mass of Spanish dollars four feet thick, and was unable to touch them owing to their great weight, and the same misfortune attended the success of an other who, a few years later, found a solid pavement of silver bars and rusted iron twelve feet square.

When operations are renewed early in the coming spring the "Lytton" will have on board an electric lifting machine with a lifting capacity of three tons. The masses of metal will be broken up by means of small charges of explosive in places small enough for the magnet to deal with. The magnet, supplied by a firm of Birmingham, Eng., has already proved successful in similar work. One of these magnets was recently used in a London dock, which threatened to become choked owing to the accumulation of scrap iron, and by its agency about 90 tons were removed in five days. Several other dock companies have now adopted the contrivance, one advantage of which, in the case of the "Lytton," is that it will be possible for a diver to be down while the magnet is working. This being, of course, quite impossible while a powerful sand pump is operating. The magnet will be of the ordinary lifting type, but with special arrangements made to insure its being watertight.

The magnet will be worked from a lift-crane on board the "Lytton," which is an exceptionally large vessel for the work on which she is engaged. She is 196 feet long and 36 feet in beam, with a displacement of 537 tons and engine of 1,000 horse-power. She is equipped with one 30-inch main-gun, having a capacity of 1,500 tons an hour, and two 12-inch guns of 800 tons capacity each. She is fitted with blacksmiths', carpenters' and engineer-fitters' workshops, has an electric search-light enabling work to be continued day and night, and carries a crew of forty-seven. A telephone communication between the divers and the deck of the vessel is provided.

Capt. C. A. P. Gardiner, who is in charge of the operations, has been occupied in salvage work for a quarter of a century, and has over 130 successful cases—and not one failure—to his credit, so that if anyone can succeed in this matter, he is certainly the man. Perhaps his most interesting "case" occurred at Cadiz, where he happened to be with his salvage vessel when a Spanish merchant ship, bound from the Barbados to Barcelona with sugar, ran aground by the rocks. Salvage was offered and accepted, the treasure being 245,000. Having satisfied himself that the bulkheads of the stranded ship were watertight, Capt. Gardiner took his vessel alongside and proceeded to flood the dry dock. It may perhaps be guessed that the Spanish skipper did not understand this maneuver, but he had no chance for thinking that the vessel would sink his ship, or for chasing Capt. Gardiner round the dock with a loaded revolver, as he did. He was, however, got under control, put in prison, and placed in the guard room. When sufficient water had been allowed to enter the hold, the vessel was raised to the surface, and before long what had been water was a mass of dirty grey trash. It was a simple matter to remove this, and the ship, being satisfactorily refloated, was towed away, and sent, loaded with its cargo, to the Barbados.

It is to be hoped that the

View toward the village of Gampel and the Rhone valley.

## The Lötschberg or Bernese Alpine Railway

Modern Engineering for the Benefit of the Tourist

By Dr. Alfred Gradenwitz

SINCE the granite wall of the Alps was first pierced thirty years ago, in order to lay through the St. Gotthard route a railway on which Italy, the land of poets and artists, could be reached more comfortably, numerous railways and tunnels have been created by the art of engineers and the enterprise of capitalists. The St. Gotthard tunnel, 14 kilometers in length, has long been outdone by the Simplon tunnel, and the most graceful scheme in bridge and viaduct construction have been realized in connection with the new Bernese (Lötschberg, Simplon) Railway to be inaugurated during the current month which combines with the most daring technical structures an abundance of surpassingly beautiful scenery to an extent never approximately afforded by any other railway line. The Lötschberg line leads through the Bernese Alps from Frutigen to Brigue in the Rhone valley and links up, on one hand the country round the Lake of Eins, Bern and Interlaken in fact the Bernese Oberland, with Upper Valais, the Upper Rhone valley—especially with the magnificent mountains and tourist center of Zermatt and Saas-Fee—and on the other hand through the directly-connected Simplon tunnel with the splendid Lago Maggiore, the Borromean Islands and the industrial and traffic center of Upper Italy: Milan, Turin and Genoa.

But the Bernese Alpine Railway is also of international importance, offering as it does to travelers from Germany to Italy a route in every way equivalent to the St. Gotthard line which affords the additional advantage of a perfect absence of smoke due to the adoption of electric traction.

In fact this is the first Alpine railway of more than local importance for which electric traction has been planned at the outset. The daring spirit in which it was conceived is the more to be admired as at the time of its inception no technical appliances able to comply with the extraordinary demands of the occasion had yet been evolved. Thanks to the initiative of the railway company, these means have now been created by the construction of

*Switzerland's great industry is to cater to the tourist, and in this industry all modern resources are strained. The current month sees the opening of another most picturesque railway line, connecting Lake Thun with the Simplon tunnel. Interest in Swiss travel is so general that we feel sure our readers will welcome an account of the new line. Those who seek more detailed information will find it in this week's issue of the SCIENTIFIC AMERICAN SUPPLEMENT—EDITOR.*

Laegghina viaduct, 122 meters long; five 20-meter spans; height, 40 meters.

locomotives more powerful than any steam locomotives in Europe, and the first section from Spiez to Frutigen has been converted into a trial line for these new engines. The speed of the trains, in spite of the high gradients of the line, which are equal to those of the St. Gotthard, Aargau and Mont Cenis routes, exceeds the figures reached on these lines. In order to illustrate the power of the new electric locomotives, it may be said that each of them can draw a train weighing 310 tons on a gradient of 27 per mille, which is the international standard fixed as a maximum whereas in the case of steam traction two powerful engines are required for the same performance. The Bernese Alpine Railway comprises the lines of Thun Spiez-Frutigen, Kandersteg-Brigue and Spiez-Interlaken-Visp, the company also runs steamships on the lakes of Thun and Brienz. The Simplon tunnel, which has been open to traffic since 1906, is also operated by electricity.

The starting point of the Lötschberg or Bernese Alpine Railway is at Spiez, on the Lake of Thun, where it connects with the Lake Thun Railway. After passing a short tunnel through the Hönrich, it enters the Kander valley beyond Spiez. At Mülmen an effort is made to transfer to the electric cableway leading to the wonderful Belvedere of Mont Niesen (7,755 feet). After Reichenbach, the intermediate station for the Kander valley, with its wealth of Alps, Frutigen, until now the terminus of the line, is reached.

The new line of Frutigen-Brigue, after crossing the Kander, rises slowly up the mountain slope on a high viaduct, and at Blau See describes a large double loop, partly in a loop tunnel. Travelers thus see the romantic ruins of the Nienburg castle at first above, then beside, and finally below themselves. Before reaching Kandersteg, the railway runs alongside the Kander Falls. Throughout the journey the traveler's eye is fascinated by the lovely mountain scenery. Atlets and Reichenbach, Rinderhorn, the Doldenhorn, peaks of Blümlisalp, the wild rocky Niesen and Finsteraar, all of which are visible

levelly south coast of Ransarögen. The Löschberg tunnel, 14,000 meters in length, shortens the Pfisterthal, passing below the Gletschen valley and the Löschberg pass, in order again to emerge at Goppentzthal. Further upbitt, the Löschberg valley, dominated by the huge Hietzschhorn, opens out into a gorge of delightfully genuine Alpine character, which, like few others, has been so far left practically untouched by the tourist traffic. The Hietzsch gorge is crossed on a most picturesque iron bridge, occupying a main span of 317 feet and two side openings, each of 140 feet.

At Hohen, the railway enters the Rhone valley, where the marveling eye of the traveler enjoys an incomparably beautiful view of the valley reaching to 1,400 feet below, the wonderful mountain outline on the south of the valley and the numerous brown villages and cottages with here and there the white church steeple. Somewhat gradually it then makes its way down to Brigue, crossing on numerous grandiose viaducts the northern slopes of the Rhone, and piercing in twenty-one tunnels the projecting rocky rib of the mountains. The view enjoyed in the vicinity of Annenberg, on Vins, lying far down in the valley, and the mountains of the Nicolai valley, the Nadelhorn and Tschuchhorn, is of surpassing beauty. From Brigue the Federal Railway trains take the traveler in a few minutes to Vins, where the cars of the Vins-Bernett Railway bound for the grand glacier and peak regions of Zermatt and Nuss Fve are waiting for him. Whereas in a northeastern direction the rail road passes through the Goms and the quaint villages of Upper Valais, in order, at Gletsch on the Rhone glacier, to connect with the Grimsel and Furka passes. Straight on, in a southeasterly direction, the electric locomotive, however, takes him through the longest tunnel in the world, the Simplon tunnel, 19,903 meters in length, to Domodossola, to the wonderful shores of Lago Maggiore and farther on, to the flourishing cities of Upper Italy, Milan, Turin, and Genoa.

The line from Spiez to Brigue is 48.48 miles in length and reaches its highest point (4,100 feet) in the middle of the Löschberg tunnel. It opens up new districts of Switzerland to human traffic and gives access to countless jewels of the Alpine world.

### The Smithsonian Institution and the Aero Club of Washington Celebrate Langley Day

IN commemoration of the work of the eminent pioneer of the air, the late Samuel Pierpont Langley, secretary of the Smithsonian Institution 1897 to 1900, the Institution and the Aero Club of Washington united on May 6th, 1913, in celebrating the seventeenth anniversary of the first aeroplane flight, that of Mr. Langley's model steam aerodrome No. 5, which twice flew successfully over the Potomac River at Quantico, Va., May 6th, 1900.

The first part of the exercises took place in the main hall of the Smithsonian Building at 2.30 P. M., when the Langley tablet was unveiled, and the Langley medals awarded to Mr. Glenn H. Curtiss and Monsieur Gustave Eiffel for expert navigation and progress in the science of aerodynamics. Addresses were delivered by Dr. Alexander Graham Bell and Dr. John Alfred Brashear of Allegheny, Pa. Owing to the absence of M. Eiffel, his Excellency the French ambassador received the medal in his behalf.

The second part of the celebration was held at 4 o'clock on the grounds of the Army War College, and consisted of a reception by the Aero Club, followed by hydro-aeroplane maneuvers.

Although Mr. Langley's first automatic aerodrome was only a model, it has been considered the pioneer of the first ship of the air. It was the first of a series of aerodromes built by Mr. Langley, which were the first to be built by man. Many years of human labor and ingenuity were required to build

Bridge above Mitholz.

Viaduct showing three railway lines above one another.

much public misconception, were soon tamed before Mr. Langley achieved his purpose and demonstrated to the world the practicability of mechanical flight. The success attending his experiments with steam models in 1900 led him to continue his work in perfecting his gasoline models, known as the "quicker sized models," which also flew successfully, and he then under took, for the War Department the construction of a steel man-carrying machine, which, although practically perfect in every point, failed to fly during the two trials held in 1903, due to a defect in the launching apparatus. This excited the ridicule of the press and the public, which neither understood the real cause of the accident in the launching apparatus nor appreciated that such a thorough experiment must be conducted in secret, and what was an accident was turned a failure. Mr. Langley was discouraged and sorrow heart-broken and never again attempted to fly the large machine, which is even today the peer of its kind, both in its lines and construction, and its remarkably light and powerful gasoline engine. This machine and the various models that preceded it are safely housed in the Institution where they were built.

When the Wright brothers had made their successful experiments they remarked that the instruction of many of their early studies and much of their enthusiasm emanated from the work of Mr. Langley. People then began to study his researches seriously and were not long in realizing the great importance of the principle which he had discovered, and the data which he had accumulated. They recalled with regret the disappointment they had offered by mutually criticism.

In 1911 the Aero Club of Washington planned to celebrate the cent of the first flight of a machine heavier than air by exercises held annually on the 6th of May, which was to be known as Langley Day. The third celebration of this event was a fitting tribute to Mr. Langley and his sincere efforts toward establishing a new science.

In commemoration of Mr. Langley's researches in aeronautics, the Board of Regents of the Smithsonian Institution caused to be prepared an oblong tablet of bronze measuring four feet six inches high by two feet five inches wide, cast from a design by Mr. John Flannagan. It represents the late secretary seated on an open terrace watching the flight of birds, while at the same time he sees in his mind's eye his aerodromes soaring high above them. The tablet bears the following inscription:

Samuel Pierpont Langley  
1834-1906

Secretary of the Smithsonian Institution

Discovered the relations of speed and angle of inclination to the lifting power of surfaces moving in air

"I have brought to a close the portion of the work which seemed to be especially mine, the demonstration of the practicability of mechanical flight."

"The great universal highway of the air is now open to be opened.—Langley, 1901."

The Langley medal was established by the Board of Regents on November 16th 1908, in memory of Secretary Langley and his contributions to the science of aerodynamics, to be awarded for specially meritorious investigations in the sciences of aerodynamics and his application to aviation. The Wright brothers were the first to receive this medal in 1910, when it was awarded to them "for advancing the science of aerodynamics in its application to aviation by their successful investigations and by their successful demonstrations of the practicability of mechanical flight by man." As already mentioned the medal was conferred this year upon two other investigators, Mr. Glenn H. Curtiss, the well known American aviator and Monsieur Gustave Eiffel, the eminent French student of aerodynamics and aviation.

## Inventions New and Interesting

Simple Patent Law, Patent Office News; Notes on Trademarks

## A Lock on the Gasoline Feed

THEIR is no great pretence of automobile thievery in this country, especially in and around the larger cities, and so much irritation and annoyance is attendant to the theft of a car that any device effective against this evil and sufficiently convenient of operation to insure its regular use should be welcomed by automobile owners.

A device is now being placed on the market which prevents thievery by placing a lock on the gasoline feed. It consists of a Yale pin tumbler cylinder lock located within a very substantial spherical brass casing, a shaft extending down ward from this ball head protected by telescoped guard tubes of steel and geared to the lock cylinder within the ball head, and a one-way valve located at the lower end of the shaft. Means are provided for securely and neatly bolting the ball head to the dash, and the construction is such as to make it practically impossible to detach the device from the dash when locked.

The valve is installed in the gasoline feed pipe by means of a double compression joint on each side of the valve. A thumb button is located on the face of the ball head, and it requires merely a quarter turn of this button to close and lock the valve. The key, therefore, is not needed for this operation and consequently it requires only one second of time to lock the device. The insertion of the key and a quarter turn of the thumb button back to its original position unlocks and opens the device. Yale locks are used, and of course, no two keys are alike.

The guard tubes and shaft are of adjustable design and are supplied in four different lengths, so that the device may be installed on any make of automobile. The benefits claimed for this device are that it absolutely precludes a lousy carburetor, it materially lessens the chances and dangers of back firing, and it prevents theft of the machine.

## The James Internal Combustion Engine

THE main objection to the ordinary internal combustion engine in use on automobiles is the noise caused by the operation of the well-known puppet or mushroom valves. Except for this objection, these valves serve their purpose admirably, but the gear for operating them, with its cranks, tapered rods and surplines, is objectionable on account of the noise with which the various parts get out of order and are broken.

An interesting engine, recently invented by T. S. James of (Missile), London, England, does away with the usual puppet valve and its accompanying gear and uses instead a single rotary sleeve valve actuated from the crank shaft by a modified gear placed upon the periphery of two flywheels. This engine, on account of its simplicity, the firmness of its parts and the cheapness of its manufacture, it is claimed, will revolutionize all gas engine construction.

The James engine, as seen in the drawing, is a four-cycle gas engine in which a single rotary sleeve valve performs the functions of the usual inlet and exhaust valves. This valve is fitted over the reciprocating piston and is operated by two modified worm gears mounted on the periphery of a pair of flywheels inside the crank casing the valve being provided with teeth on its lower part which mesh with the worm gearing on the flywheels.

The cylinder head contains two ports, one for the inlet and one for the exhaust between which is placed the usual spark plug. The upper end of the valve has four ports which successively register with the inlet port spark plug and exhaust port in the cylinder head to produce the suction compression and exhaust strokes of the engine. It will thus be seen that these ports are automatically closed every few revolutions. The valve is also provided centrally with a stem over which the cylinder head is fitted. A set of nuts on this stem provides for the adjustment of the valve in relation to the cylinder head, the last being secured to

The gasoline lock.

Dashboard of a car showing the location of the lock. Thus the theft of a car is prevented.

the casing by the usual bolts. The teeth on the valve and worm gears are so related as to provide for proper timing for the various strokes of the engine.

By this construction the valve is moved only when under atmospheric pressure, no movement taking place during the compression or during the expansion strokes, and, since the two surfaces between the cylinder head

and the valve are ground flat, it is said no leakage can occur. It is also claimed that there is no difficulty in the lubrication and no danger of overloading.

## A Photographic Alarm Clock

By Walter Isendahl

IT is now possible to purchase an alarm clock which calls the hour in a clear human voice, instead of announcing it by the ringing of a bell. The photographic alarm clock is not a new invention. A clock of this sort was shown at the Paris exposition in 1900, but it was very different from the new clock described below. The Paris clock was a huge construction, which resembled a clothes-dress. It stood six feet high, weighed a hundred pounds and cost about \$2,500, while the new clock is only 18 inches high and costs only \$35. It can be adjusted to call out each quarter of every hour, and the call can be repeated by pressing a button. When it is used as an alarm clock, the alarm pointer is set at the desired hour—say, seven o'clock. Promptly at the stroke of seven the clock begins to call "Seven o'clock! Seven o'clock!" and continues calling until the alarm is turned off or until 15 minutes have elapsed, when the call is changed to "Seven fifteen! Seven fifteen!" and so on.

At any time during the night a touch on a button evokes the proper call for the current quarter hour. Calls in thirty-five languages are provided, and the change from one language to another is easily effected.

The mechanism of the speaking clock is simple in principle. The photograph record is made on an end-on band about 2 inches wide and 40 inches long, which is carried by a number of cylinders. The 24 calls which are required in order to announce each quarter-hour of the twelve hours, are recorded in 24 parallel grooves, each of which occupies the whole length of the band. The reproducing needle has a sapphire point, and the record band is made of very hard material. When the band is injured by use or accident a new one can be substituted without difficulty.

The needle is kept accurately in the proper groove by a spring device, similar to that employed in computing machines, which is so contrived that the clock can be set by turning the hands either forward or backward, without waiting to allow the intervening quarter-hours to be called. In the operation of setting the clock, the needle moves across the band without touching it, and when the clock is started, the needle falls accurately into the groove corresponding to the changed time. If, however, the hands should be moved while a call was being uttered, the needle would be dragged across the grooves and the record would be injured. The sound is intensified by a small horn, which is in close to the clock case.

The accompanying illustrations show the external appearance and the interior mechanism of the clock. The talking mechanism is in the lower part, between the vertical plates  $F_1$  and  $F_2$  (Fig. 1) and beneath the horizontal plate  $F_3$ , which supports the clock train and alarm mechanism. The clock work has an anchor component, protected by a sapphire plate  $A$ . The regulator can be adjusted from the outside by means of a slit in the dial. By moving the lever  $J$  a piece of clock spring can be inserted through a slit into the cap  $K$ , in order to stop the balance wheel and prevent the clock from starting. The lever  $L$  is the alarm lever, actuated by the spring  $P$ . The alarm can be stopped by pressing the button  $A$ , which protrudes from the case.

The driving spring of the photograph is contained in the barrel  $O$  (Fig. 2), and the winding post, pinion and wheel are indicated respectively by  $B$ ,  $N$  and  $G$ . The last wheel of the photograph train (Fig. 1) engages with the sapphire sector of the regulator  $J$ . The lever  $K$  (Fig. 1), connected with the time clock, keeps the photograph regulator slit from touching until the proper moment, when the lever falls and releases the photograph mechanism. The second hand is shown drawn along by the rotation of cylinder  $W$ .

than the products of fractional distillation.

The fifth and last means of increasing the available gasoline supply is by lowering its Baumé gravity. It is probable that the specific gravity of commercial gasoline will be dropped another notch by next summer. Much of the liquid gas gasoline is used for blending with heavier distillates, and it naturally requires other than gravity tests to determine the characteristics of such blended gasoline.

With the exception of importation these various methods of augmenting the available quantity of gasoline are now in active operation, and every increase in price is a stimulus to additional output.

This brief review of market conditions shows that the problem of an adequate supply greatly overshadows the collateral problem of the increasing cost of gasoline.

Fortunately we have two alternative liquid fuels immediately obtainable. Alcohol and kerosene oil offer an ample supply of satisfactory fuel to the power-driven vehicle. We need not discuss alcohol at this time, further than to point out that it is a very good fuel and can be used advantageously if gasoline advances to 20 or 25 cents wholesale. In fact there is no valid reason why alcohol should not be used today in cars selling around \$5,000. Of course, special engines with appropriate compression are required, as gasoline engines are not adapted for alcohol.

Predictions heretofore made in regard to denatured alcohol as a fuel have not yet materialized. Nevertheless, it is probable that alcohol alone could hold down the price level of gasoline from advancing appreciably beyond 25 cents to 30 cents in tank car lots.

But the one best fuel is oil.

Oil combines more advantages than any other. It is the fuel of the future and the fuel of today. In connection with gasoline or alcohol it is much cheaper, safer, better adapted for shipment, more uniform in quality, more highly concentrated, more powerful.

Even in the far distant future, when the crude oil output falls below the world's demand for liquid fuel, a practically unlimited source will be the great oil-bearing shale which cannot be worked profitably at the present low price of kerosene.

After many years of observation and experience I am convinced that as a medium for generating power for transportation, on land or water, mineral oil or kerosene is the most valuable general purpose fuel known to commerce. This statement is made in full recognition of the fact that the oil engine has always had less commercial popularity than either the gas or the gasoline engine.

In former days the oil engine was heavily handicapped by the high price of the oil. Oil production is in excess of consumption. Kerosene is now the by-product and is quoted at 60 per cent less than gasoline.

[From an address delivered by John A. Boor before the Society of Automotive Engineers (Indiana Section) at the Clay pool Hotel, Indianapolis, February 1919.]

Determines the Better Fat in Butter and Dedicates Patent to Public.—By a method patented by Roscoe H. Shaw of Washington, D. C. No. 1,002,008, it is sought to determine the fat content of butter by placing the butter in a container with hot water, then centrifuging the mixture, removing the aqueous solution from the container and adding thereto an equal mixture of sulfuric acid and water, when the contents are again centrifuged and the acid solution is partly driven off. After this the contents are subjected to a second centrifuging and the container and butter fat are weighed. This patent has been dedicated by the inventor to the public.

"Gee! I'm Glad I Have On B. V. D."

THAT'S what the cool, comfortable, coated man is thinking, while the cross, comfortless, *coatless* ones are eyeing him enviously. Don't you be caught without B V D when warm days "put you on the griddle." B V D. weather is here—B V D is sold everywhere

To get genuine B V D, get a good look at the label. On every B V D undergarment is sewed

# Are These Things There?

By R. F. Olds, Designer

In buying a car in 1913 here are some things to look for. By them judge how the car is built, how up-to-date it is.

And judge by them if the maker gives you the very best he knows.

## Outer Features

Note if the car has left-side drive, like the leading cars today. Does the driver sit close to the cars he passes, or on the farther side?

Has the car electric set-in dash lights, or the old, projecting lamps?

Is it under-tired or over-tired? That makes an enormous difference in your tire upkeep.

Is one front door blocked up by levers? Or do levers block the passage between the two front seats? If so, the driver half the time must enter from the street.

Is the upholstery genuine leather? Is the hilling the best curled hair? Does the finish show the final touch in every part and detail?

## Inner Features

How many Timken bearings has the car? They cost five times what common ball bearings cost.

In Reo the Fifth there are 15 roller bearings, 11 of which are Timkens.

In Reo the Fifth there are 190 drop forgings, used to avoid the risk of flaws.

The steel is made to formula. It is analyzed twice to prove its correctness.

The gears are tested in a 50-ton crushing machine. The springs are tested for 100,000 vibrations.

We use a \$75 magneto, a doubly-heated carburetor, a smokeless oiling system, big, strong brakes.

We give to each driving

part vast margin of safety—50 per cent overcapacity.

Each engine gets five long tests. And each, after testing, is taken apart and inspected.

If you seek a durable car, a trouble-proof car, and low cost of upkeep, these are points to consider.

## Skimping Is Now Unpopular

Many a car has gone into obscurity because the maker skimmed.

I go to the other extreme in these days—after 26 years of car building I spend about \$200 per car for features unusual in this type of car.

Men who buy my cars expect it. They expect low cost of upkeep, freedom from trouble. They expect a five-year-old car to run as well as new.

I have built such cars for legions of men. And every Reo the Fifth which goes out this year marks my

level best. In the years to come, you men who get them will realize why I do this.

It means slow, careful building. It means endless inspection. It means grinding parts over and over. It means doing in a \$1,095 car what users expect, and what makers must give, in a \$4,000 car.

## Where I Save

Such a car at such a price is made possible in this way.

We have a model factory, so finely equipped that engineers from everywhere come here to inspect it. Here we build the entire car by the most efficient methods.

Then this entire factory is devoted to a single model.

Every machine, tool and mechanic is adapted to its production. We save in this way about 20 per cent under what it would cost to build two or three models.

Thus we give you a car, built as we describe, at this matchless price.

## The Demand

Our output is limited to 50 cars daily, so cars are never rushed. Last April and May the demand for our cars ran five times our factory output.

We have worked all winter, at fullest capacity, to avoid that condition this spring. But a shortage is inevitable. If you want spring delivery on Reo the Fifth, please see your dealer now.

## Our Unique Control

In Reo the Fifth you find a one-rod control. And that rod is out of the way—between the two front seats.

All the gear shifting is done by moving this rod only three inches in each of four directions. It is as simple as moving the spark lever.

Both brakes are operated by foot pedals. So there are no levers, side or center. The driver's way is clear.

No other 1913 car has this form of center control. And a car without it will seem inconvenient when you see what this form means.

This control rod comes at the driver's right hand, for the car has left-side drive.

A thousand dealers handle Reo the Fifth. Write for our catalog and we will direct you to our nearest showroom.

**Reo the Fifth**

The Editor is always glad to receive for examination illustrated articles and to return them promptly. He is also glad to receive the articles short and the facts of the contributions will be made known to the contributors. Accepted articles will be paid for at regular rates.

The purpose of this journal is to record accurately, simply, and interestingly, the world's progress in scientific knowledge and industrial achievement.

### Shall We Retard, Divert, or Confine Our Flood Waters?

EVER since our issue of May 3rd in which we devoted considerable space to the control of the Mississippi River, the Editor of the SCIENTIFIC AMERICAN has been receiving quantities of letters on this most important subject, which was to be expected when we reflect that the drainage area of the Mississippi system involves about two fifths of the country. However, while many of the letters have been highly appreciative, others have called us to account for clamoring the levee system and for not favoring this or that bill introduced before Congress. The Editor has a collection of these bills before him. About a dozen have been introduced since the present session, many of them having been of little importance for the reason that they call for local appropriations.

But the particular bill which has figured conspicuously in most of the letters is one that was introduced by Senator Newlands before the session of Congress. This provides for the creation of a Board of River Regulation, an appropriation of fifty million dollars annually for ten years to be used in overcoming the floods of the Mississippi and the Sacramento and San Joaquin rivers, and for co-operation between the Government, Bureau and States, municipal and local agencies.

We have no fault to find with the broad purpose of this bill. There is no shadow of doubt that the control of the Mississippi River with its great tributaries is a national problem. A large majority of the States of the Union contribute in whole or in part to the enormous floods that pour down through the Mississippi Valley. We thoroughly believe in co-operation between State and Federal authorities in the control of these floods and we heartily oppose that section of the bill which aims to secure financial co-operation of States to an extent at least equal in amount to the sum expended by the Federal Government. Only by co-operation can such an enormously large water course be controlled.

Nevertheless, the SCIENTIFIC AMERICAN must take exception to certain provisions in the bill which although made in good faith, clearly indicate that the framers of the bill had no adequate conception of the vastness of the subject he was dealing with.

Col. Townsend's report, published in the SCIENTIFIC AMERICAN SUPPLEMENT of May 3rd discussed this matter at length. He showed that in order to hold back the hundred thousand cubic feet of water per second it would be necessary to refortify a territory equal to one sixth of the area of the United States. Furthermore, it would take a hundred years for such a forest to grow and shed enough leaves to form the spongy humus necessary to retain this amount of moisture.

The reservoir idea put forth in the bill is also based on a popular misconception of the vast amount of water that flows down the Mississippi system. It is usually contended that the reservoirs could be made to pay for themselves owing to the amount of hydro-electric power that could be generated by the use of their waters. But in order to obtain a working head such a reservoir would have to be placed near the headwaters of the rivers and tributaries where they would be of little service in taking care of the floods on the lower reaches. It has been demonstrated conclusively that a reservoir will only regulate the flow of a river in its immediate vicinity, but will have but little effect on points a hundred miles or so farther down stream. Col. Townsend has shown that if a reservoir were placed near Cairo, Ill., it would have to cover something

like seven thousand square miles and would have to be excavated to a depth of fifteen feet in order to take care of the water that rises above the normal banks of the river. This would involve an excavation nearly five hundred times as great as that of the Panama Canal.

The SCIENTIFIC AMERICAN believes in reforestation. Our most serious problem is to extend the forest and to wisely manage it. We favor the construction of artificial reservoirs wherever possible. With the increasing demands on our steadily diminishing coal supply, we shall have to turn to hydro-electric development. We favor every reasonable means of controlling the flood waters and irrigation systems where needed. But what has all this to do with the control of the Mississippi? We cannot encourage the false hope that any of these schemes, taken singly or collectively, will have any material effect on the enormous torrents of water which pour down the Mississippi Valley.

A bill was introduced before the House of Representatives a few weeks ago, which purports to provide an entirely new solution of the Mississippi problem. It calls for the purchase by the Government of a strip of territory two miles wide running parallel to the Mississippi to the west, this strip to be extended eventually from the Gulf to Cairo, Ill. Along each edge of this ten mile strip a levee is to be built and into the channel thus formed, the flood waters of the Mississippi are to be poured, thus giving them with a new outlet to the Gulf. The idea is far from new. Thirty years ago the outlet system of the control of the Mississippi was widely discussed and condemned largely because of the fear that the Mississippi might take the notion to leave its course completely and leaving the cities along its banks high and dry. It was proposed at that time to connect the Mississippi with the Atchafalaya River and allow this to take off the surplus waters. The fear of such a sudden diversion of the main channel of the Mississippi led to the suggestion of the control of flood waters in the Atchafalaya at various intervals. These consisted of large willow mats weighted with stones and sunk to the bottom the idea being that they would retard any scouring that might result from the increased volume of water pouring down the Atchafalaya. This was not considered wise to let the overflow of the Mississippi run into the Atchafalaya which it does at the present time. The ground sills are still in place and they have successfully prevented the Atchafalaya from being scouring out to a depth as to change the course of the Mississippi.

It is the purpose of the present bill before Congress to provide an Atchafalaya two miles wide, so that the Mississippi River could never rise to anything like its present stage, and the premises of the present bill seem to realize that a channel such as this would fill with sediment. If the current were not swift enough to carry the material on down to the Gulf and if it were made swift enough might not the river take the bit in its teeth and run down the new channel instead of the old? The Mississippi problem would not be half so difficult if it did not carry so large a percentage of sand. But why discuss this proposition? Would not the cost of purchasing a ten mile strip along the Atchafalaya be practically prohibitive? Would it not call for the building and maintenance of double the present levee system? And then what advantages would it have over the present system, in which large areas are occasionally flooded? Why not condemn the present levee system and be done with it? However, hasn't the levee system already, rivetted itself? This bill there have been only two serious breaks, one at Mayaguez, Miss., and the other near Lake Nat. Zoulsana. But the rest of the hundreds of miles of levees stood up well. Apparently to control the lower Mississippi, it is necessary to make the levees higher and stronger. The fear that the bed of the river is being raised by the levees is groundless. It has been conclusively proven, not only in the investigation of the Mississippi River, but in that of many rivers abroad, that the levees do not tend to raise the bed of the river to any appreciable extent. The Mississippi River bed is estimated to be one tenth of a foot higher this year than it was a hundred years ago. The present high water readings merely indicate that the levees are doing their best to confine the river to its course, and we must continue to build them higher and higher until they are capable of taking care of the maximum flood. Any other form of control is hopelessly inadequate.

### Personal Error and Efficiency Engineering

IT is the part of the scientific man to discover the truths of nature. But as there is nothing absolute, all his observations are necessarily more or less vitiated by errors. It is not enough for him to reduce these errors to a minimum. He must expose himself to the possibility of error, he must make his mistakes, and their influence upon his conclusions and operations which he bases upon his observations. All these points have received due attention, and a fairly

complete "theory of errors" thus developed forms part of the stock-trade of every worker in the exact sciences.

But scientific observation and manipulation is merely a refinement of common every-day practice, and errors of observation and of operation play an important role in many of our most serious mistakes. Many a man earning capacity and even his life depends upon the perfect working of his senses and limbs is often not realized by him until age, illness or accident has impaired it. Not only is there such a qualitative relation between a man's physical and mental well-being and his earning power, but accident and his insurance companies, as well as courts in deciding actions for personal injury, deal themselves confronted with the problem of establishing some quantitative estimate, however crude, of the value of a man's organs, their influence upon his earning capacity or "efficiency."

It would be a poor policy that should take note only of the value of lost faculties. To the efficiency engineer more than to any other person we owe it that our attention has been drawn to what might be termed "false notions," i. e., errors of operations, and their influence upon the efficiency of the industrial worker under normal conditions. And not merely qualitative, but quantitative studies, made with watch and camera, have furnished us a truly scientific groundwork on which to base our calculations. The result has been a secure greatly increased efficiency. It is sometimes fairly supposed that the additional output thus harvested is the result of increased pressure placed upon the worker. If instances of this kind have occurred, they are entirely for the purpose which the originators of the movement for increased efficiency had in view; the output is to be increased, not by increasing the pressure of work, but by decreasing the resistance, by eliminating waste in lost motion and misplaced energy. Such increase in output must result on the whole in a gain to the entire community, perhaps not always in a gain evenly distributed among all members of a community, but nevertheless, in a gain to all.

### The International Magnetic Survey

SCIENTIFIC features of the remarkable work carried out by the International Magnetic Survey, the action of the Carnegie Institution—on, for example, the construction and the cruises of the non-magnetic yacht "Carnegie"—have attracted general attention, and have been extensively written up in the popular as well as the scientific press. In the other hand, persons who actually have occasion to use magnetic data, for either scientific or practical purposes, have been wondering how soon the institution in question would put the results of its vast undertaking into statistical or cartographical form for the benefit of the world.

There has now been published the first volume of a series under the general title "Researches of the Department of Terrestrial Magnetism," in which all the results of the department's work will be collected as far as possible. The first volume is entitled "The International Magnetic Observations, 1905-1910" and is Carnegie Institution Publication No. 178. Future volumes will contain the results of the work on land subsequent to 1910, of the cruises of the "Carnegie," 1905-06, and the work done on the "Carnegie" from 1910 onward. While these publications will deal chiefly with terrestrial magnetism, they will also contain occasional memoirs on atmospheric electricity and other subsidiary subjects.

The Department of Research in Terrestrial Magnetism, to give it its full title, was founded by the Carnegie Institution for the purpose of carrying out a general magnetic survey of the globe. A major part of its work is twofold comprising the correlation and consolidation of the national and local magnetic surveys already in use, in various parts of the world, and the execution of a new land and sea magnetic surveys where none have been undertaken. The latter part of the programme involves a good deal of downright exploration in little-known lands and unexplored seas. This volume now before us, which deals entirely with observations made on land, is illustrated with photographs, showing in local color, showing field stations all the way from China to Peru. It should be explained that such photographs are not merely ornamental, but serve the practical purpose of identifying the exact location of the stations, so that they may be reoccupied at any future time for the purpose of making comparative observations. No less interesting than these photographs are the narratives of the journeys made by the various observers, often brilliant and full of interest. The latter part of the volume is the tabulation of the observations.

A full account is given of the instrumental equipment and methods of reduction. It is explained that the publication of the results contained in the present and subsequent volumes has been delayed by the many problems presented by the observations. However, over the greater part of the globe are to be published on a uniform basis.

# Electricity

The Electrical Export Figures for March have just been published by the Bureau of Foreign and Domestic Commerce. They show a remarkable increase over the figures for March, 1917. The total for the month this year was \$2,494,774, whereas for the corresponding month last year the total shipments amount to \$1,838,080. The total for nine months ending with March is \$10,246,000 as against \$14,733,896 last year.

**Charging Stations for Electric Vehicles.**—The New York Electric Vehicle Association has formed a committee to look for the use of electric automobiles. It contains a list of charging stations in the city of New York, on Long Island, up the State as far as Hudson, east as far as New Haven, west as far as Boston and south as Philadelphia and Atlantic City. The handbook also lists a chapter on the care of both lead and nickel-iron batteries.

**The Largest Turbo-generator in the World** is being built for the Commonwealth Edison Company of Chicago, by the General Electric Company. It is of the horizontal turbine type and will generate 30,000 kilowatts. The overall length of the machine will be 90.5 feet and it will be 18 feet 4 inches wide by 15 feet high. It will run at 1,500 revolutions per minute. The generator will be a 25-cycle, 3-phase machine with two poles, and the output will be 1,925 amperes per phase with a voltage of 9,000. The total weight of the turbine and generator combined will be about 1,000 tons.

**Wireless in Canada.**—At Le Ton, Manitoba, the southern terminus of the Hudson Bay railway, there will soon be erected the second largest wireless station in Canada. It will include four 250-foot steel towers and will cost about \$100,000. Plans are under discussion for establishing several wireless stations in the far Northwest, via from Athabasca Landing up the Mackenzie River to Herschel Island, in the Arctic Ocean, and from there to Rampart House, in the Yukon. Such stations would be valuable for scientific purposes, especially for collecting meteorological reports, and would also be serviceable to the Northwest mountain people.

**Non-absorbent Insulation in Motors.**—A motor used in tropical climates is apt to develop defects that do not appear under other conditions, for the reason that it is subjected to high temperature and a great deal of moisture. It has been found that the sheet insulation used in the slots in stators is responsible for a good deal of trouble. Where this weakness has developed the motors have been renowned with misanthropic insulation and this has cured the trouble. A similar condition of affairs might result even in temperate zones, where the motor is subjected to a damp climate subject to high temperatures. In such position it is advisable to use a non-absorbent slot insulation.

**Indirect Street Lighting.**—We have been taught to appreciate the advantages of indirect, direct-indirect and semi-direct lighting over the dazzling illumination and injurious glare of naked lamps. But so far these improvements have been applied only to interior lighting. Our streets are still lighted by direct illumination. Could not indirect lighting be employed here too? It certainly would be preferable to have a street lighted throughout its length by a soft evenly distributed light in place of the present system of bright spots with jet-black spaces intervening. At a recent meeting of the Illuminating Engineering Society of Great Britain, J. Darragh suggested that lights should be illuminated in this way by casting the light against the building from which it would be reflected to the street again. In this way the glare of the lamp would be overcome. Objections to such a system immediately present themselves. It would be difficult to place the lamps in such a way that there would not be objectionable shadows on the opposite of the building while using at the same time a reflecting area sufficiently large to provide efficient illumination.

**Platinum Terminals for Quartz-tube Mercury-arc Lamp.**—In order to obtain higher efficiency and better light values from mercury arc lamps, it has been the practice to substitute quartz tubes for glass, and to operate the lamps at higher voltages and consequently higher temperatures. One of the principal difficulties encountered has been that of sealing in the terminals of the metal electrodes. The coefficient of expansion of quartz is  $0.5 \times 10^{-6}$  and that of platinum is  $9 \times 10^{-6}$ . This great difference of expansion has made it necessary to employ some other metal. Now tungsten with a coefficient of expansion of  $3.5 \times 10^{-6}$  is being used. The difference of the coefficient expansion is such that the tungsten can not be sealed directly in the quartz, but instead is sealed in a borosilicate glass of the same coefficient of expansion and of a high melting point, while between this seal and the quartz tube a number of glasses of varying coefficients of expansion are used, providing what is known as a "graded seal." It has been suggested that the use of introducing electrode into a bulb could also be used in conjunction with ordinary incandescent lamps. If so, it would materially reduce the heavy demands of the electrical industries on the expensive and precious metal platinum.

# Science

**The Willard Gibbs Medal Presented to Dr. L. H. Baekeland.**—On Friday, May 16th, the Willard Gibbs medal was presented to Dr. L. H. Baekeland by the Chicago Section of the American Chemical Society.

**A Magician's Club** has been founded in London and has just opened its clubhouse. The membership comprises more than 200 professional and amateur conjurers. The clubhouse will include a museum of magic, a library of some 500 technical works on conjuring, and an experimental room with appliances for making new magic.

**The Time Service of the U. S. Naval Observatory** has become more generally useful than heretofore through its transmission by radio-telegraphy, especially since the opening of the great wireless station at Arlington. The noon signal has been transmitted by radio-telegraphy to ships at sea since January, 1905, and it is believed that this observatory was the first by over the years to have its time regularly transmitted in this way. The utility of the service on land is illustrated by the fact that thousands of jewelers are receiving or arranging to receive their time from the radio signals.

**The New Ministry of Agriculture and Forestry** under the Chinese Republic will be extensively offered by young Chinese men who received their technical education in the United States. Lai Kuei Liang, a 1906 graduate of the Massachusetts Agricultural College, has been appointed vice minister of agriculture and has charge of the Department of Agriculture Journal. Dr. Joseph A. 1906 graduate of the same institution, has been the translation of foreign agricultural literature into Chinese for this ministry, while H. Jen, a classmate of Mr. Hsieh, is director of the agricultural experiment station at Mukden, Manchuria.

**Cellulose from Asparagus.**—The American consul at Hamburg has reported the details of the process invented by Prof. Otto Reinke for the recovery of cellulose from asparagus waste (from canning factories) and from the asparagus stalks that mature after the edible crop has been gathered. Heretofore these residues have been practically worthless except as fertilizers, as they have but little nutritive value when used as fodder, and attempts to utilize them in making coarse paper or packing material have not resulted satisfactorily. After undergoing a relatively simple treatment, the cellulose, after treatment, they yield a beautiful pure cellulose, which may be used for bandages, blasting material, paper, tissues, fine felt, cardboard, etc.

**A France-British Scientific Congress**—Special interest attaches to next year's meeting of the Association Française pour l'Avancement des Sciences, which is to be held at Havre, probably September 4th to 12th. A large number of British societies are to take part in the meeting. There are 180 British societies affiliated with the British Association for the Advancement of Science, and it is hoped that the French Association meets in Australia, and comparatively few members will be able to make the long and expensive journey, and from those whose expenses are to be paid out of funds raised for this purpose in Australia. Accordingly, as Havre is comparatively near England, it would not be surprising the conference of delegates from the affiliated societies at that place, in conjunction with the meeting of the French Association. It is hoped that American scientific societies will also be represented at this joint meeting.

**The Greatest Wind Velocities** are undoubtedly those occurring in tornadoes. The recent destructive storms of the Mississippi valley have furnished some examples, but this question cannot be answered satisfactorily. In the Annual Report of the Chief Signal Officer for 1875, p. 435-436, there are some estimates to the velocity of the wind in a tornado of that year from its barometric effect, and, as a point of reference, it is given by a telegraph pole, which drove three inches into the trunk of a tree, and so on. A velocity of wind sufficient to produce such results could not have been much less than that of a cannon-ball, or somewhere between that of a bullet and a cannon-ball. It is doubtful whether we shall ever have instruments for measuring such winds, but on the other hand something might be done toward providing stronger instruments than those now in use, so that in winds of ordinary hurricane force the instruments would not be carried away just when about to make its most interesting record. The need of such an instrument is pointed out by Maxwell Hill, government meteorologist of Jamaica, in an account of the hurricanes of last November in that island. A Robinson anemometer exposed to the hurricane of November 18th, 1878, was blown away when rotating 120 miles an hour. Probably the highest velocity ever recorded by an anemometer was 180 miles an hour, on Mt. Washington, January 11th, 1878, but this and all other high records of anemometers (J. K., of the Robinson type) are well known to be greatly in excess of the true velocities.

# Automobile

**A Solid Pneumatically Cased Tire.**—In a patent, No. 1,059,111, Philip H. Calum of Birmingham, Ala., presents a vehicle tire having an outer solid rubber tire with recesses upon its inner side and an inflatable inner tube with integral air cushions which fit into the recesses in the solid rubber tire so that the solid tire protects the inner tube and the latter is held from motion relatively to the solid tire.

**Testing Carburetors.**—The Benz firm, the well-known automobile and internal combustion engine constructors of Mannheim, recently donated the sum of \$12,500 of a view of starting a fund for installing a special laboratory for experiments upon carburetors for gasoline motors. The laboratory is to be installed at the Hochschule of Karlsruhe. In addition to this, it is stated that different substances have been collected for the purpose of founding a mechanical testing laboratory and shops at the same institution.

**Tire Makers Adverse to Tire Fillers.**—Whether or not there is any particular virtue in the various substitutes for air that have been developed and urged upon the public, the tire makers themselves do not seem likely to them at all. As a matter of fact, they strongly advise against their use and have stated that guarantees will be rescinded if any other medium than air is used in their engines. They give as their reason for the edict that the fallen air has been found to be a poor substitute for air and that the deteriorating effect it has on the rubber.

**How Will Automobiles Be Improved?**—It is difficult at this time, when automobiles have reached such a high degree of excellence, to indicate wherein improvements will be made. In talking, however, with the writer, the owner of a medium-grade machine complained of the paint peeling off the metal body of his machine and expressed the belief that improvements will be made either in the paint itself or in the method of its application which will increase the durability of the painted surface upon the metal body of the machine. At any rate, the field is a large one for the inventor along this particular line.

**Kerosene Without Gasoline Priming.**—Despite the advances that have been made in the employment of kerosene for engine normally constructed to burn gasoline, either preliminary heating or the use of gasoline as necessary starting medium is still considered a necessary invention to overcome the difficulty, the Chambre Syndicale de l'Industrie du Petrol, of Paris, has decided to offer two prizes in connection with a proposed competition to discover the best means, if any means exist, to start engines without the necessity for using gasoline for starting purposes. The prizes are \$1,000 and \$500, respectively.

**Storing Gasoline in Scotland.**—A Glasgow newspaper explains a method of keeping petrol or gasoline to avoid waste by evaporation which was being proposed in Glasgow by the local body of his machine and expressed the belief that improvements will be made either in the paint itself or in the method of its application which will increase the durability of the painted surface upon the metal body of the machine. At any rate, the field is a large one for the inventor along this particular line.

**City Gas for Engine Testing.**—By way of reducing overhead expense, one of the largest of the Detroit automobile manufacturers has adopted the novel expedient of testing his engine on city gas. Preliminary to being tested on city gas, the engine is run on its own power for a period of about an hour and a half before gasoline is so small an item. Under the new regime, however, it is estimated that sufficient city gas to run one engine as long as it would run on two gallons of gasoline at 17 cents a gallon, which is the wholesale price, costs in the neighborhood of 8 cents. Inasmuch as the manufacturer in question will build at least 150,000 engines during the year, it may be appreciated that the saving for fuel will be considerable. The same method has been adopted and used in some of the large Coventry factories with gratifying results.

**Accelerators and Inactive Bracing.**—It is a psychological fact that the immensity of collision causes the driver of a motor car instinctively to brace himself against the impending abash, which brings to light that if he has his feet on the clutch pedal, he will not, one on the clutch pedal and the other on the brake pedal, the greater the braking the better will be the result, for the clutch then will be disengaged and the brake applied automatically. The danger arises, however, when, as so often is the case, the right foot rests not on the brake pedal but on the accelerator pedal, when the driver's mind is so before the mind acts quickly enough to cause the foot to be shifted, then results in the car being rushed full into the danger. The moral is obvious, and should be plain to the person of average intelligence without further disquisition.

## A Telephone Transmitter Without a Mouthpiece

By H. R. Van Dewater

UNTIL the presentation of Prof. Whitehead's paper on the oscillations of a telephone diaphragm at the annual meeting of the A. I. N. E. at Boston last year, but little was understood regarding this important detail and therefore practically all the commercial types of instruments have employed the same type of diaphragm as found in the very first instruments designed. The invention of most inventors has been directed toward refining and perfecting the structural details, and especially the resistance coil. Although this is a very important part, it is no more so than the diaphragm. Tyndall has found that the points of greatest vibration in a circular diaphragm clamped at its periphery are at a point midway between the center and the edge. Whitehead found that the diaphragm had two distinct motions, one superimposed on the other, one consisting of circular nodes and the other of oblique or diameter nodes.

A new transmitter is illustrated herewith which is the result of our five years of careful investigation of the properties of vibrating diaphragms. Instead of employing a loose diaphragm made of some dead metal such as aluminum which is commonly employed for the purpose, phosphor bronze is employed, which is found to produce an initial tension. The diaphragm is then formed without drawing the temper, into a pan shaped disk the projecting edge of which is securely clamped, leaving the central portion free to vibrate like a drum head.

A resistance coil of the ordinary type is connected to the center of the diaphragm by means of a spider shaped member having a plurality of feet which are soldered to the inner surface of the diaphragm. These feet, being equidistant from the center, pick up the sound vibrations at the maximum point, and it will be noted that this method of connection is entirely different from the ordinary method wherein the coil is connected to the diaphragm at the center. The coil with the diaphragm is placed in a back casing, the various parts being illustrated in the accompanying photograph. A connection is made between the four electrodes of the coil and an insulated terminal carried on the casing in such a manner that the circuit is confined to the electrodes and granular carbon, so that no part of the casing or diaphragm is in circuit. Certain other details of construction, all very simple and easy of manufacture, result in an instrument which is absolutely watertight, as it may be immersed in water for hours or even days without any damage whatsoever. The casing being of brass and the diaphragm of phosphor bronze, there is no corrosion such as commonly occurs in transmitters where aluminum diaphragms are employed.

As the assembly of the instrument is considerably increased by the improved diaphragm construction, it is possible to dispense with the usual mouthpiece as commonly employed. Telephone companies agree, especially in the case of deck sets, that the annual maintenance cost for mouthpiece replacement is as high as 50 cents per telephone. The new instrument eliminates this charge, as the mouthpiece consists of a flat perforated metal guard which is practically indestructible.

Being water proof, this transmitter of course a perfect solution for the telephone men with in mine and railroad telephone police boxes, testing sets, and instruments used in other exposed locations. It can be used in the operating rooms of hospitals, as it can be flooded or immersed in a sterilizing solution without injury. The coil, being in an air and water tight chamber, cannot deteriorate, and being directly surrounded by the metal casing, interior air spaces being reduced to a minimum, the heat due to the passage of current through the carbon is rapidly dissipated.

The sanitary features of this new instrument should be evident, the mouth piece can be thoroughly cleaned, and it is that it will be often wiped off, which is not the case with the usual funnel shaped mouthpiece. From tests made in several of the university laboratories and by the writer, the instrument in its commercial form, was found to average from three to seven miles better in terms of standard cable than transmitters of ordinary construction.

The accompanying photograph represents the transmitter without guard or back shell, submerged in a fish globe filled with water. The looking glass, behind the globe reflects the rear casing and wires. This exhibit was shown at the meeting of the National Independent Telephone Association at Chicago, Ill. The transmitter was connected with a testing set, adjusted

for use on a long distance telephone line and operated by two sets of fifteen dry cells, each set in series, and both sets connected in multiple. The room at the hotel was fitted with the usual telephone subscriber set, and the submerged transmitter, through the testing set, was connected with the city telephone line. The Chicago operator was requested to connect with a certain office in New York and the following tests were made.

Talking in an ordinary tone, six inches away from the fish globe, against the submerged transmitter, a conversation was carried on for over five minutes and New York reported that the transmission was perfectly distinct, and that the voice was heard in natural tones.

Telephoning from Chicago to New York with a submerged transmitter.

Following the conversation a repeating watch was held against the side of the globe and the striking of the hours and quarters was distinctly heard in New York. The transmitter was submerged from 8 P. M. Monday, February 17th, until the close of the convention, Thursday, February 20th, 8 P. M., or 75 hours. Then it was taken back to New York and again submerged in a globe of water, giving perfect transmission.

## The Anesthetizing Machine of Prof. Dubois

By Jacques Boyer

IN a recent communication to the Academy of Sciences of Paris, Prof. Raphael Dubois exposes the method of producing anesthesia by way of the alimentary canal, which has lately been proposed by various writers, and shows that his anesthetizing machine, herewith

The anesthetizing machine invented by Prof. Raphael Dubois of Lyons, France.

illustrated, offers the most certain and most uniform means of administering chloroform.

The apparatus comprises a pump, an automatic device for introducing a measured quantity of the anesthetic, and a chamber in which the dose is evaporated. The pump has a piston of peculiar construction which is moved by turning a handle. At the end of each stroke of the piston a definite volume of air enters the pump barrel, carrying with it the vapor of the measured quantity of anesthetic that has been automatically poured into the evaporating chamber by the descent of a plunger into the vessel containing the liquid

anesthetic. In the rubber stroke of the piston the mixture of air and vapor is expelled from the pump and replaced by an equal volume of a pure anesthetic air mixture. In this way a continuous flow of air standardized mixture can be maintained.

The mask with valves, which is commonly used when the anesthetic mixture is drawn from a gasometer, and which may cause asphyxiation through disengagement of the valves, has been replaced by a valvular mask, which allows the patient to breathe, without annoyance, in a current of air containing a known and constant proportion of anesthetic. In this method no danger attends an excess or a deficiency of administration of the mixture, and the only inconvenience caused by supplying it too slowly is the possibility that the patient may be roused from the anesthesia by the inspiration of fresh air.

At the beginning of the operation the plunger is raised to the top of its course, the liquid anesthetic (chloroform or ether) is poured into its container and the handle is turned until the lower face of the plunger touches the liquid. The operator then applies the inhaling mask to the face of the patient and turns the handle until the dose of anesthetic has been expelled into the evaporating chamber.

After anesthesia has been produced a nasal tube, or the tracheal cannula which the photograph shows lying on the glass table of the apparatus, may be substituted for the mask, if an operation is to be performed on the face.

The advantages of the method of Prof. Dubois are manifold. In the first place, the surgeon knows exactly how much anesthetic is being administered, which is not the case when the liquid is introduced by manual methods, even when it is applied to drops with a registering pipette. In the second place, anesthesia is produced in a regular and continuous manner. This arrangement is particularly important for the prevention of vomiting, which is a symptom of return to consciousness. Finally, the excitement attending the initial stage of anesthesia is entirely eliminated, or, at least, greatly shortened and diminished, even with alcoholic patients. The applications of the machine which have already been made have proved the correctness of previously published assertions of the production of anesthesia by mechanically compounded mixtures, and it is possible that the majority of surgeons will decide to employ this thoroughly scientific apparatus.

## A New Theory of Sleep

THAT we sleep, not because we are exhausted, but in order to avoid being exhausted, is the way in which the German physiologist, Chapard, formulates a new theory. According to this conception, which has been further elaborated by Trueman, sleep is not the result of fatigue, but an impulsive self-defense process, which the body from time to time conducts against itself, so to speak, in order to get rid of waste products before they have a chance to become injurious. This view is expounded in an article by Dr. Adolf Koelach in *Die Woche*.

He draws attention to the fact that just as combustion of fuel for the production of heat and energy is always attended by ashes and slag, so the slow combustion which produces heat and energy in the body by means of metabolic changes, is likewise attended by waste.

We read: "Since the secret never comes to rest voluntarily or shut themselves off from the outer world, a point would eventually be reached when the organism would perish as a victim of general nerve exhaustion."

"In order to hinder this, Nature arranges, before, i. e., before exhaustion can seriously injure the organism, to set in motion that opposition current which we term sleep."

Again, "The sleep-endowed animal tends to take its 'sleep at night, since the stimuli which govern the animal's vital activities are then cut off.'"

For animals endowed with other special senses, but not with sight, the sight is not so great a factor. "When an owl blocks its sight, it does not shut itself out from the outside world by closing its eyes, but it does so by turning its head to the side, so that the light is not directed into its eyes."

It is believed that a sufficient degree of anesthesia is one of the latest means which nature uses in order to get rid of waste products before they have a chance to become injurious. Koelach has also pointed out that the

# Seeing Under Water

## How Things Look From a Fish's Point of View

By the Berlin Correspondent of the SCIENTIFIC AMERICAN

**O**PHIOGRAPHY, thanks to the many investigations made from a geographical and physical viewpoint, has, during the last few decades, made enormous strides. We are now able, e. g., to gaze with a fair approximation to truth, how light is distributed in the depth of the sea or a lake, what gradations of light and color are to be expected at certain depths, and what are the conditions of temperature from the surface down to the bottom. However, nobody seems so far to have examined in a comprehensive manner the question, as to what an eye placed below the surface of the water would see and perceive, and what impressions it would receive from this rather unusual standpoint, of its immediate surroundings in the water, but especially of the world outside.

The experiments recently made on vision below water by a German scientist, Mr. Otto Baron v. n. s. A. von Munch, are therefore of more than passing interest and likely to appeal to the physicist as well as to the fisherman and angler. In order better to understand their purport it will be as well, by way of introduction, to summarise the physical conditions on which vision is based.

It is well known that a beam of light striking a transparent substance (e. g. water) of different density from air, undergoes at the boundary a variation in its direction, on account of the difference in the velocities of

situation vertically above our heads, i. e., in the zenith (clouds in the sky, etc.) have preserved their true shape, but as our gaze sweeps down toward the horizon, objects will change their wondrous forms until at the horizon itself all vertical distances have become so greatly shortened that nothing can be recognised.

Fig. 1.—Diagrammatic explanation of underwater vision.

What is the reason of this strange phenomenon? In connection with our reference to total reflection we have seen that there are no visual beams connecting the water and the outside world, beyond an angle of

incination of  $48\frac{1}{2}$  degrees. In fact the whole hemi-sphere of  $180$  degrees, constituting the outside world, is reproduced in the water within a cone of  $97$  degrees. While a fish thus is able to see all objects of the outside world—even an angle coming toward the water's edge—he sees everything, with the exception of the zenith, deformed and on a shortened scale. Moreover, the cone of  $97$  degrees just referred to is, at the limiting angle of total reflection, filled by a colored fringe due to the dispersion of colors in water, the red edge being turned downward and the blue and violet upward.

The horizon of water dwellers thus is extremely limited as compared with that of dwellers in the air, while even the form and size of objects in the air appear to them different from what they do to us. However, a person placed in the water will be even more surprised on viewing an object situated partly in air and partly in water.

Let us first consider an ordinary measuring staff, as in Fig. 1, half of which is situated in water and half in the air. An eye placed under the water at A sees the submerged portion in its natural shape and size within the angle  $\angle$ . The portion outside, however, becomes first visible in the cone corresponding to total reflection (angle  $\angle$ ); the upper portion of the staff thus appears in the direction of the limiting angle of total reflection. Being situated immediately above

Fig. 2.—How objects are distorted when viewed from a point under water.

The eye A placed under the surface WW sees a four-headed and four-legged monster entirely disconnected from the head and upper body.

light in different media. Again, the ratio between these velocities in two given media is a constant figure known as their index of refraction, which is expressed by a mathematical relation between the angles of incidence and refraction respectively. Hence a beam of light entering air from water under an incidence of  $48\frac{1}{2}$  degrees is broken along the water surface, those beams which come from angles greater than  $48\frac{1}{2}$  degrees can no longer issue into the air, but are reflected in their entirety from the water surface, the limiting angle being called "angle of total reflection."

What, then, may we expect to see on entering the water of a lake and trying to view the outside world from this unwonted position? Framing the water surface to be perfectly calm, we immediately witness the following remarkable phenomenon: Whereas all objects immediately surrounding us in the water are seen in their natural size and shape, anything situated outside the water, i. e., the whole of the outside world, appears extremely distorted. It is in this distorted manner that the outside world is seen by a fish.

Fig. 4.—How a man standing in water looks to a fish. The fish is deceived by refraction while the disconnected head is displaced by refraction.

Fig. 3.—View from under water of a partly submerged tree.

Fish-eye view of a horizon walking in water.

Note the reduction of the horizon's legs on the under surface of the water.

the water horizon, the whole of this portion appears extremely shortened, in fact as a small object far distant from its direct continuation in the water, in an oblique direction above the water surface. Thus the staff is seen as two separate and altogether dissimilar parts.

Within the angle  $\angle$  is seen the reflection of the lower portion, and in the angle  $\angle$  the remaining lower surface of the water up to the limiting angle of total reflection. In the angular space  $\angle$  the eye sees the bottom of the lake from the staff to the bank and in  $\angle$  the reflection of parts thereof.

Observation with the naked eye under water is unsatisfactory because it is impossible to stay under until the objects are undistorted and one must limit himself to observing his immediate surroundings in the water. As his eye is only adapted for vision in air all objects, on account of the different refraction of the water, will appear hex and without any sharp outlines. The hands and body will have a sponge-like, jelly fish like appearance, even the stones on the bottom looking like parts of a pulp mass. Any more distant objects,

for instance the body of another human being, will appear quite indistinctly, as though through a thin dirty pane of glass or a greenish haze. The results of Baron Ambrose's actual experiments in the latter fairly clear water of the Wachenloose.

But he has made more interesting observations by means of a mirror placed under the surface.

It was interesting to ascertain how the silver-white armor of scales surrounding the abdomen of fishes is an outcome of adaptation to a bright reflection actually existing at the water surface, the fish becoming practically invisible to their foes. The supposition that such a reflection could be seen by the eye, whether on account of total reflection no light is allowed to come out of the water was found to be erroneous, the water surface being even darker than the surroundings and showing the color of the lake (green or bluish green). On the other hand, the elements corresponding to the cause of outside vision is extremely bright, and if the surface be even slightly stirred, each wave will produce a flickering glimmer so that a fish in this region doubtless becomes invisible to his eye, on account of his silver armor.

As regards the appearance of outside objects, houses and trees situated close to the water's edge are hardly recognizable as such, so flattened do they appear, while their lower portions are entirely invisible. Nor are the stones at the water's edge seen any longer. In fact, the roof of the houses and the tops of the trees look as though they rose directly from the water. Even high mountains appear again from the middle of the lake as though they were slightly more than low eminences or at most flat hills. Most common, however, is the appearance of a single standing nearby at the water's edge, his legs nearly up to the knees disappear, only the body being visible from this point, but compressed like a ball. What wonderful colors are, however, seen over this man and his surroundings! His face, arms, hands—in fact everything—is shining in the most beautiful colors of the spectrum, each bunch of the adjoining trees, every leaf is surrounded by a spectrum of its own, so that one could believe the trees to be dotted with shining rainbow pins. Wherever the bright sky is visible through the foliage, red, yellow, green and blue draperies are seen. The distant mountainous banks of the lake appear so flattened as to look like a dark horizontal stroke, but even they have their colored fringes, though only the red and yellow can be distinguished. If, now, the mirror be placed somewhat more obliquely, the true shape of an object is seen to be rendered the more falsified as it is situated closer to the zenith. Still, it retains the wonderful colored edges above referred to.

Fig. 2 represents the impression received by an eye placed in very clear water, of a man walking up to his hips in water. Will the monster approaching the observer be recognized as a human being? In accord with the broken appearance of the measuring staff (Fig. 1), the water dweller sees the part of the human body immersed in the water, walking on the bottom of the lake in its natural size and shape. This part of the body, however, is reflected at the same time from the lower surface of the water, thus producing an identical though reversed image with the feet pointing upward as a continuation of his lower body. The upper body which emerges from the water, first becomes visible in the angular space corresponding to total reflection inside which the outside world is reproduced. It is thus seen from the eye A upward in an oblique direction in such a manner that when a colored lead is thrown on the water surface only the flattened upper parts of the body are visible, surrounded by a luminous colored edge all the remainder having disappeared. In fact, the man will produce on the water dweller the impression of a stream bed. For the same reason, the view of the same phenomenon. The view toward the stone bank of the lake (Fig. 3) is likewise remarkable. On account of the similarity of the reflection with the real picture of the lake bottom, the eye seems to look into a tapering narrow alley paved with stones on the top and beneath, above which the water's edge appears in the same manner as above described. The reflecting water surface is only visible where it comprises bubbles or floating objects.

Another method of studying underwater vision was described in the *SCIENTIFIC AMERICAN* of December 25th 1912. It involves the building of a subaqueous chamber in which fishes may be watched and photographed. It was of two underwater photographs taken by Dr. Francis Ward, showing a herring walking in the water. The mirror effect at the surface of the water is clearly brought out although the reflection is not perfect because of the ripples stirred up by the bird.

#### The Aeronautical Society's Coming Aviation Meet

A THREE-DAY aviation meet will be held at the grounds of the Aeronautical Society of Great Britain, N. Y. beginning on May 30th. Lloyd H. Scott will demonstrate his bomb-dropping

apparatus with which he won the Michelin prize in France last summer, and Cecil Peck, Capt. Baldwin's youthful aviator, will blow up a paper fort by means of wireless electric waves sent from his biplane. George Dwyer will make flights in his new monoplane, and the new following-surface monoplane of H. G. Nichols will receive its initial try-out. Shooting at small balloons from an aeroplane will be attempted again and Latham will jump from Harry Brown's Wright biplane in mid-air and again demonstrate Leo Stevens' new "safety pack"—a light silk parachute worn like a knapsack and which opens automatically about the instant the man leaves the machine, and without his doing anything whatever. Every aviator and passenger should wear one of these "all" life preservers in case of a fall.

#### A Straight Line, Apparently, Not Always the Shortest

LIKE all good puzzles, this one is very easy when you know how.

Suppose there sits upon a table a six-sided block of glass which is  $7\frac{1}{2}$  inches long and 3 inches each wide and high.

On the right hand end, at a point one fourth inch from the front and half way between top and bottom, sits a fly.

He is required to crawl, over the outside of the block, to a similar point diametrically opposite the one he now occupies, on the other end of the box.

He is a very busy fly, and has a strong desire to crawl as little as possible.

What is the least possible distance he can cover

Showing that sometimes a straight line is apparently not the shortest distance between two points.

In getting from point A to point B? (See sketch.)

This looks easy. It seems obvious that the fly has only to crawl straight out to the front, straight along the front of the block and straight back along the left hand end, to make a perfectly straight line between the two points. A moment's thought shows that he can crawl one fourth of an inch to the first end, seven and one half inches on the front, and two and three quarters inches on the other end—total, ten and one half inches.

But a really clever fly would crawl from point A to point B without covering so long a distance!

There are plenty of paths the fly can choose. He can crawl diagonally from point A to any other point he chooses and take another diagonal from his first turn, he can crawl along the edge and over the corners, but how can he select a course which will be less than ten and one half inches?

Having puzzled your friends with this, take a piece of paper and lay out a diagram (see second sketch), which is the block "unrolled," or taken apart, and on it draw one of one quarter of an inch to the actual inch. By cutting this figure out of paper and folding it along the lines, it can be made into a representation of the glass block.

If, now, you will draw a line from point A to point B, and measure that line you will find that it totals exactly ten inches the fly had to crawl over. Yet when the unrolled box is folded, it is obvious that it would take a very clever fly, and a clever boy, too, to think out the apparently devious line of travel which is, in reality, the shortest distance between the two points.

But, in spite of the apparent contradiction of mathematics in this little puzzle, it is strictly according to the letter of the law, for the line from A to B is to be regarded as the hypotenuse of a triangle, in which the sides are lines drawn from A and B to a meeting at right angles. Measure these sides in your mind and

you will find that one is eight inches and the other six inches.

Now, the hypotenuse of a right angle triangle is the square root of the sum of the squares of the sides. The square of six is thirty-six, the square of eight is sixty-four, their sum is one hundred, and the square root of one hundred is ten—which is the distance from A to B by your unrolled block.

#### Transporting a Locomotive on a Cableway

AMONG the problems confronting the engineers who are constructing in the West the enormous storage dams for irrigation, transportation of heavy machinery is one of the most difficult. The location of the sites for these dams is usually in a region remote from railroads and often quite inaccessible until highways have been carved out of the steep-walled canyons.

Arrived at the site of the big work, the moving of heavy machinery and materials from one side of the canyon to the other is a problem calling for considerable ingenuity and nerve on the part of the engineer. In late years wonderful progress has been made by the manufacturers of cableways and their efficiency has increased greatly. To-day the cableway when properly installed becomes the great transporter and solves in a large measure the difficulties which attend the work when working in deep canyons through which flow turbulent streams.

The series of cableways erected at Elephant Butte, New Mexico, have been employed to weighty advantage in transporting material thousands of tons of material and machinery. Recently it was found necessary to transfer a 20-ton diesel engine across the canyon. The method employed is shown in our frontispiece illustration. Fearing the weight of the engine might too severely test the strength of single cables, the material was swung across on two cables and was safely landed at its destination on the other side. The length of the cableways from one tower to the other is 1,400 feet and the height of span above river bed is about 280 feet.

The Elephant Butte dam, which is to be one of the greatest works of the Reclamation Service, blocks the entrance to a comparatively narrow walled canyon in the Rio Grande River, about 120 miles north of El Paso, Texas. The structures will be of rubble concrete gravity type built straight and not curved like the Roosevelt dam in Arizona. It will have a maximum height of 275 feet, will be 1,200 feet long on top and contain 500,000 cubic yards. The reservoir created by the dam will have a superficial area of 40,000 acres and a capacity of 2,672,000 acre-feet. The reservoir will have a capacity of 50,000,000 cubic feet more than that of the Aswan in Egypt. It will serve a double purpose in that it absolutely protects the lower valley from destructive floods and insures an abundant water supply to 190,000 acres of land in New Mexico, Texas and old Mexico. It will restore to cultivation and intensive agriculture thousands of acres which have been abandoned by reason of water shortage. It will provide homes on the land for 8,000 families and increase the taxable wealth by many millions of dollars.

#### The Current Supplement

THE old fashioned gold miner has been succeeded by a steel monster which digs out in one minute more earth than the huskiest man could have uncovered in a day. The largest mechanical gold dredge in the world is illustrated and described in this week's issue of the *SCIENTIFIC AMERICAN SUPPLEMENT*.—Extracts from the report of the American Committee on Aerodynamics on the conditions of aerodynamics in Germany to-day, brings much valuable information to those interested in the newest branch of engineering.—An oscillating propeller for ships, which is claimed to possess certain advantages over the ordinary screw propeller, is described by Dr. H. C. Vogt of Copenhagen, Denmark.—In wireless telephony it has been found necessary to substitute for the Hertzian oscillator a generator adapted to furnish currents of such high frequency as 200,000 cycles per second.—The new method of determining the age of fossils, described by Dr. J. W. Alexander.—Dr. J. W. Alexander illustrates by means of examples—one thousand analyzed rocks—a new system of classification for igneous rocks, based upon their chemical composition.—An article by Mr. F. A. Perret on the forecasting of El Niño is illustrated with some very fine photographs of lava streams obtained by means of a cinematograph lens.—J. S. Stone's article on the propagation of high frequency electric waves along wires is concluded in this issue.—Mr. P. G. Keegan writes on the chemical nature of Florida Blue.

The Iceberg Patrol.—It is announced from Washington that the revenue cutter "Sagoy" and "Miles" have been detailed to patrol the transatlantic steamship lanes to prevent shipping against icebergs, supplementing the work of the British vessels "Hector," a notice of which we have shown previously. Ship-owners' notes will be made to the Navy Department.

Pipe lines from canal to Natchez power house.

Natchez power house—central station for a farming district.

## Agriculture, Electricity and Irrigation

### Intensive Farming Made Possible With the Electrically Driven Pump

By Putnam A. Bates, E. E.

**B**ETTERMENT of the farmers' condition and improved efficiency in all farming operations are the needs of the hour. Bankers and business men's associations, federal departments, agricultural colleges and important engineering organizations are giving careful study to this basic foundation of the country's welfare, and yet there is perhaps no one improvement that may be counted on so radically to benefit the farmer as the introduction of electricity on the farm.

The electric farm, however, is not a new idea, for farms well worthy of this appellation have been in successful operation approximately for ten or twelve years. But there has been very little dissemination of existing knowledge of the use of electricity in agriculture, with the result that farms electrically equipped are under suspicion and regarded as impractical hobbies.

Here I shall endeavor to show that such derision should cease at once, for we may look for a general use of electricity on the better class of farms in this country before many years have elapsed, and electricity is now being utilized for light and power purposes on a much larger number of American farms than many of us realize.

Let us consider for a moment the farms of the Southwest. In some sections of that fertile country, well protected by the mountain ranges, are to be found many electric farms, with buildings lighted by electricity and many of the laborious operations accomplished by the use of electric power. There were our first electric farms, the period of establishment corresponding with the development of the water powers of the nearby mountains.

On the majority of southwestern farms, irrigation is practiced, and naturally electricity was first made use of for pumping purposes. Next, under the influence of progressive operators at local central sta-

Captured waters—forebay of the power canal.

Turbulent waters of the Natchez River above the intake canal.

tions, it was generally introduced for light.

I saw electric lights and electric flat irons in use in farm homes of the Pacific Coast eleven years ago. The people were content to enjoy the advantages which electricity from water power made possible to them, but did not seem to regard their advanced conditions as unusual. Their farms were, in fact, electric farms and their industries, dependent upon the produce of the land, were, as they are now, practically all operated by electricity. I refer to the canneries, fruit packing houses, etc.

The conditions surrounding the farming districts in southern California, for example, at that time, were such that it would have been unusual to adopt any other form of energy, a combination of circumstances being largely responsible for this fortunate situation. The high tension transmission service systems were then new and the companies desired business, and we did not have the gas engines we possess to-day. The efficient and reliable gasoline and fuel oil motors were not developed until several years later. There was pumping to be done, for irrigation was rapidly coming into favor, and, naturally, the electric companies secured the business.

It is difficult to determine whether the power plants, supplying service at rates within the reach of all, made the irrigated farms, or if the electrical load, which these farms warranted, insured the success of the power developments. Both interests seem to have worked together, and in some instances practically the entire supply of the central station current was at once utilized for lighting, heating and power uses on the farms. This was the case ten years ago in the instances I speak of, and according to recent reports, the situation has not materially changed.

## Franklin Institute Treasures

Discovery of Keeley's Motor, the First Yale Lock, Franklin's Static Machine and Other Interesting Models in the Underground Storage Rooms of the Old Building

By H. D. Jones

Model of Stephenson's engine, 1814.

A RECENT overhauling of the contents of the cellars of the old Franklin Institute Building in Philadelphia has brought to light a number of interesting models that had been allowed to rust in out of the way corners of the underground storage rooms. Some of these proved so valuable, when examined by members of the Board of Management, that it was determined to select the more interesting for a permanent museum in the new building that the Institute will occupy in the future. The models thus selected have been cleaned and classified and many are now to be seen in the museum at the Institute.

Among the models is the original Yale lock, made by Linus Yale in 1855. It is a clumsy looking contrivance with a key big enough to match those of the old-time safe, but its principles were as sound as the perfected Yale lock of the present day. A writer with a turn for mathematical calculations spent a long time trying to estimate the number of arrangements of manipulations made possible by the lock, but found it would take more than a lifetime to enumerate

them. The lock is a very ponderous affair, but it must be remembered that in those days the old idea that weight made strength still prevailed.

The story of the Keeley motor hoax will live long.

the frauds is the Redheffer perpetual motion machine, which claimed to work on the principle that leaved arms on an inclined plane exercised a constant force to push away the planes. This force was supposed to rotate a

large wheel. The model actually shows that the force used to de-rotate investigators of this method of overcoming the rules of nature was obtained through a small wheel, worked by clockwork concealed in the hollow of one of the posts. The clockwork was set going by winding one of the knobs seen in the photograph of the model. A humorist at the Institute has set at the top of the Redheffer machine a small model of a man trying to lift a trunk while standing on it.

More valuable from a scientific viewpoint than the models of the perpetual motion deceptions is the model of the Stephenson engine, showing the wheels supported on pistons working in steam cylinders instead of springs. The en-

gine weighed about eight tons. The wheels were connected by a chain. The engine proved defective in

Oliver Evans' "Orvator Amphibolus."

its interest will be enhanced by the preservation in the Franklin Institute of the model of the remarkable motor that Keeley built to deceive intending investors and enrich his inventor until the fraud was exposed after Keeley's death. For twenty-five years Keeley astounded eminent scientists of Europe and America with the machine that he claimed had solved the secret of perpetual motion. The inventor of this machine would start his device going, apparently, by playing a tune on a mouth organ. He convinced many clever men that he told the truth, and stock in the new concern sold freely. To the day of his death, Keeley declared that his discovery was a genuine one, and it was only when the house in which the machine was placed was thoroughly overhauled that the colossal fraud was discovered. Keeley had wired the walls of the building. He ran his machine by high pressure hydraulic power. When the wires attached to the machine were the subject of investigation, Keeley would file them to show that they were solid and could not be used for any purpose other than that for which they were attached. Pieces of wire thus filed are to be seen at the Franklin Institute. The broken pieces show that the wires were hollow and that the inventor of the wonderful motor carefully stopped his string short of perforating the engine, which would have exposed the fraud.

There are several other perpetual motion machines in the collection, none of them different in design from the Keeley motor, none the creation of misanthropes who manipulated, but had faith enough in their ideas to carry them to the Patent Office for protection. One of

Simple Patent Law; Patent Office News; Notes on Trademarks

## Wave Motors on the Pacific Coast

By L. McCally Edholm

THE sight of the ocean uselessly expending its energy on the sands of the shore has started many a man to puzzling over a way to capture this power and put it to use. Just now a number of wave motors are being tried out at various points along the Pacific coast and some of them are of unusual construction.

One of these motors has been installed at Venice, California, and pumps the sea water to a height of forty feet. To generate electricity it is planned to pump this water into a storage tank, allowing it to run through the turbines. A wooden frame is built out from the pier about twenty feet above the water and this supports the motor, which consists of a large wooden wheel ten feet in diameter mounted on a steel shaft. Two heavy timbers extend from the wheel to two feet below the surface of the water, where they connect with a wooden piano placed to receive the full force of the waves. The incoming breaker dash against the piano driving the wheel forward, while the receding wave force it violently out again. This motion oscillates the wheel and the power is transmitted to four pumps by means of steel wire cables. The sea water is pumped to a height of forty feet through a three-inch pipe. As the tanks have not yet been planned to receive the water, the spray can be seen in one of the accompanying photographs falling in a shower.

Fully a score of different wave motors are being tried out along the coast. A motor near San Diego works on a somewhat different principle from the one just described, as it is proposed to generate power without the use of a pump. A photograph of this plant is reproduced here.

At Huntington Beach a company has recently secured a concession on the municipal wharf on the promise that it will install a wave motor and supply free light to the town. Hence its development is being watched with much interest.

## How to Sell Inventions

By William Atherton De Fay

OF course the most directly important point in invention is reaping money upon the children of one's brain thus called into being. There is always a secondary sentimental satisfaction in an invention when it becomes an item large or small, in the progress of the times and contributes its share to the added comfort and well-being of human kind. The inventor is likely to appreciate his service to his fellows and prize this benefit in proportion to its

real worth. But if he gets far in invention he must likewise be a practical man and make money out of his labors. This money is, quite naturally, the immediate object of his activities.

Advising the inventor as to the best method of procedure in marketing his patents is rather a difficult task. There are no well known roads to wealth through invention that may be very definitely pointed out. The men who have been successful, however, have a good deal to say on the subject and their advice ought to be of the best. In that they agree as to general principles a good, middle-of-the-road course may be prescribed which, when modified by the exceptions in any given case, ought to get it value out of almost any patent.

sure the necessary profit. There may be articles in the market that will compete and this competition must be met. Therefore the inventor should think of the practical problems of the market before he gives much time to a prospective invention.

Upon the completion of his patent, those being of record at the Patent Office, the inventor will receive circulars from half a dozen sources, embodying proposals to market these patents. These circulars will tell of the various methods used by their senders of bringing patents before an industrial world which is waiting on tiptoe for just such inventions. When the patentee answers one of these circulars he will find that a fee in advance is required on one pretext or another. He sends the fee. This is the last he ever hears of the circular

to whom you may go for advice. You should remember that the advice of only successful people is worth while. Go to the man at the top. If he is interested something may be accomplished, and the enthusiasm of the unimportant man avails nothing.

Criticism, condemnation, ridicule of your invention may not justify its abandonment. Many of the greatest inventions have been ridiculed in the beginning. Make the critics show you why your invention is no good. If you are an intelligent man and they cannot show you why, keep up your confidence and your efforts. This criticism will breed new ideas and improvements.

Finally, if your idea is any good, it will come through this fire of criticism. In the

meanwhile it may have attracted backers. The successful men who know most of the men of the industry in which your invention is to be used are the very kind of men who are most likely to finance its manufacture. They understand its usefulness and its possible market. They are successful people and therefore are likely to have money with which an enterprise that promises great profits may be put on its feet. They have financial friends who have confidence in their judgment.

If you have selected important people in your canvass, people who know your line, you will not have gone far before you will have interested someone who may help you. Probably some two or three men may be brought together to start the manufacture of your device. You furnish the patent and they furnish the money. You should be ready to make liberal terms with such people. You may have a patent that is worth a million dollars. You are actually justified in giving away to the right man one-half of that patent, or a \$500,000 value. It is good business on your part to do this if you select the right man as the beneficiary. This course should lead to the manufacture of the article. The right man being interested in the patent may bring it and you into touch with the right people to make the biggest thing possible out of your invention.

Your invention may be of such a nature that its sale may not be practicable in this way. It may be merely an extraordinary complicated machine and not a commercial article in itself. It might be the invention, an attachment to a typewriter. This attachment, let itself might not have been an independent machine, but it might be of use only in connection with a typewriter. The manufacturer of the typewriter will want to know the value to a certain extent. The inventor should get along with the manufacturer and

The 16-foot wheel rocked by the waves operates a set of pumps.

Wave motor near San Diego that does not employ a pump.

Pumping set driven by the wave motor. Note the spray in the background.

The inventor should have thought of the sale end of his creation before he spent much time and energy upon it. An invention intended to add to the convenience of three-legged people might be of great worth to those so constituted but the possible sales would be so few that its development would not be profitable. There are many more two-legged people and it would be better judgment to invent for this larger field. It would be more practical to patent a cotton picker than a daisy picker because there is a bigger industry demanding the former. An improved shoe would have a material advantage over an improved glove for there are more shoes worn than gloves.

The inventor should first ask himself if there is a demand for the thing he proposes to develop. He should attempt to get the viewpoint of the possible purchaser and manufacturer of his invention and judge from that angle whether or not his idea is worth while. He should remember that great numbers of his article must be sold to make its manufacture worth while. He should consider the probable price that the purchaser will be willing to pay for each article. He should determine whether or not the article can be manufactured with sufficient cheapness that its sales may as-

senders. I have never talked with an inventor who has ever sold anything through these self-styled benefactors of the ingenious. It would seem that it would be entirely possible to conduct a business of this sort that would be mutually beneficial to the patentee and the manufacturer but as far as I am able to ascertain, no such business exists.

So it is the part of wisdom for the inventor to forego this immediate profit of possible benefit. He has a better way nearer home. Whoever he is and wherever he lives there is, near him, someone who is an authority upon the very sort of thing he has invented. If it is an appliance that has a place in any phase of railroad activity, there are men in the repair shops of the nearest railway division who will be excellent judges of its merits. If it is to be used in the building trades, ask the men who are putting up the business blocks of your home town about it. The local hardware man should be a fair judge of the usefulness of any ordinary tool. It is not likely that you will invent anything with reference to factory machinery unless you live in the atmosphere of a factory. Then, if you have your authority to whom to show your model. Whenever you visit and whenever you live there are plenty of people near

PATENT ATTORNEYS

# PATENTS

If you have an invention which you wish to have made, you can write fully and freely to Wm. C. C. for advice as to the best way of obtaining protection. Plans and sketches or a model of your invention and a description of the device, explaining its operation.

All communications are strictly confidential. Our own practice, besides over a period of more than thirty years, enables us in many cases to advise in regard to patentability without any expense to the client. Our Head Office is in London, and we are in communication with the Patent Office in London, and the Patent Office in London, and the Patent Office in London.

## Agriculture, Electricity and Irrigation

(Continued from page 475)

except that both supply and demand for the current have increased.

Some of the farms in the vicinity of Visalia, Cal., are typical of the conditions suggested. The majority are small truck and fruit farms ranging from 10 to 40 (an average of about 20) acres to each person. These farms may be termed electrically irrigated farms, for in practically all cases the farmers operate irrigation pumps by electricity, and the details of this class of electrical supply are well established.

In the State of Washington, we find similar interesting conditions where there is electric service for power and lighting use in all the newly settled farming districts.

We should study closely, all that has been projected in these great, electrically operated irrigation farms of America, for surely there can be no more important work for us in this day of agricultural investigation, than to apply in all sections of our country the principle of efficiency which underlies the utilization of our resources, exemplified by these illustrations.

During the primitive period of the history of American farming there was too much extensive husbandry and not enough intensive farming. Land was abundant and cheap, and much of it destined itself. The pioneer, believing the supply of land inexhaustible, selected a patch, killed off the trees, cultivated it until available plant life in the soil was exhausted, and then moved to another field. In this way, the increase in population being rapid, great tracts were made on the country's natural soil resources. In time, all the naturally drained and naturally watered lands were utilized, and a great portion exhausted, temporarily at least, and the reclamation of our western semi-arid and prairie land, along scientific lines, should be an object lesson to us all. Those lands now now require irrigation, and have become valuable. Additional fertile, low cost farms, by the tens of thousands, are needed more and more as our population doubles.

We have learned from these western developments that for proper crop culture, all lands should be drained and all crops need water. And it is not sufficient to have water by the deluge—from time to time—but water must be applied in such manner as to provide the stimulant necessary to plant life, in order that development may be greatest at certain stages of growth. This is especially interesting, in that it is a claim for the merits of irrigation, not only in the arid country, but in sections where there may be an abundant rainfall.

So it is seen that scientific agriculture, irrigation and electricity have formed a powerful combination. The natural waters are played with at will, sometimes passing directly to the land, but more often the turbulent mountain streams are carried for miles in flumes or canals, only to give up energy at several points on the way, and ultimately to irrigate the land by gravity, or pumping, as the conditions may require.

Another method is to drain the marsh land and pump the water thus available to the higher places adjoining. Suit able crops are then grown on land of any level, with the result that the area for production is materially increased.

Irrigation is the key which rejuvenates, as well as unlocks the fertility of the soil, and to comprehend its importance in agriculture, one must appreciate the fundamental principle governing plant growth and soil culture.

When we consider that all plant life must have moisture, and at certain stages of growth more water is required than at other times, it will be seen that to be able to control the supply of moisture places the growing of crops largely under the control of man. That is to say, we are now able to aid the plant growth in a way that nature does not do alone.

# Vitalized Rubber Diamond (No-Clinch) Tires answer your demand for "More Mileage"

Our chemists have discovered a scientific process of toughening pure rubber.

All types of Diamond Tires are now made of Vitalized Rubber—a flint-like, road-resisting rubber that retains all the young, lusty vigor of the pure gum with no loss of elasticity.

## Perfect 3-Point Rim Contact an additional Diamond advantage

Our engineers have built up and torn down thousands of experimental tires in an effort to produce a perfectly constructed tire that would give you the "More Mileage" tire you have demanded.

Cross Section of Diamond Safety Tread Tires

In Diamond Tires each thread of fabric and every ounce of rubber is combined to give the greatest strength and resistance, with no unbalanced strains at unsupported points—Perfect 3-Point Rim Contact.

Add to these advantages the No-Pinch Safety Flap, for inner tube protection, and, if you wish, the now famous Diamond Safety (Squeeze) Tread, and you have absolutely the most satisfying tire money can buy.

So this time buy Diamond Vitalized Rubber Tires—you can get them to fit your rims at any of the

dealers

LAKE LINES

## Men Enjoy This Trip

Whether on a vacation or business trip, there's solid comfort on our magnificent lake steamers. The above view shows the handsome "City of Detroit" room, with pipe organ, on our newest and largest steamer, "City of Detroit III," operating between Detroit and Buffalo.

## The Water Way

Fuller, Detroit, Buffalo and Mackinac

"The Floating Home Away From Home."

The marvel of marine science, costing \$1,500,000, has many new and attractive features never before seen on any fresh water steamer, and found only in the finest metropolitan hotels. Excellent dining service, cozy, lavishly smoking rooms, writing rooms, drawing rooms, imported Orchestrons, perfect attendance with meals for the ladies. All Mackinac Railway Devices Complete and Approved by U. S. Government.

Your Railroad Tickets Are Good on D. & C. steamers between Detroit and Buffalo, Detroit and Cleveland either direct, or via Buffalo, and Buffalo and Cleveland either direct, or via Detroit. Through tickets are also available for the entire route. Prompt connections with railroads for all principal cities. For illustrated booklet and copy of Great Lakes route, including Detroit, to

spected in mid territory the same as if such laws were in full force and effect.

## Rehabilitating the Roman Campagna

A PROBLEM that has baffled the agriculturists of Italy for centuries—the rehabilitation of the Roman Campagna—seems now in a fair way of being solved. The Campagna is a vast plain surrounding the city of Rome. Its soil is fertile, it is well watered, and the great city at its center offers a market for all that it can produce. Once it was densely populated and prosperous, but to-day it is a desolate wilderness. Not a tenth of its surface is under cultivation, it has no towns, but only a few scattered and ruinous wayside inns and the miserable huts of a handful of herdsmen and vine-dressers. Its deplorable condition is due entirely to the fact that throughout the summer it is a hotbed of malaria. In winter it is habitable, and then many herdsmen drive their cattle hither from the surrounding mountains to graze in the rich pastures, but in the month of May they return to the higher and more healthful land.

Even in ancient times the Campagna was not free from fever, but the presence of a large population kept the disease in check. In the light of modern knowledge this is explained by the fact that the land was kept drained, and there were few neglected places in which mosquitoes could breed. The depopulation of the Campagna was due to the incursions of barbarian hordes, and subsequently to the establishment of great estates in place of the small holdings of earlier times.

In the last half century many attempts have been made by the government and by philanthropists to colonize the Campagna from other parts of Italy, but until recently these undertakings have all failed, entailing immense loss of life. The government went so far as to decree the confiscation of large estates that should be left uncultivated by their proprietors. The latter made every effort not only to attract a peasant population, but to protect settlers from the dreaded scourge at one time it was believed that the planting of eucalyptus trees would check the malaria, but this expedient, after being tried on a large scale, was found to be of no avail.

Since 1900 the Italian Red Cross Society has maintained stations in the Campagna for the treatment of the fever-stricken people. About the same time the part played by mosquitoes in communicating malaria became known, and the screening of houses was advocated. The government immediately took steps to screen all police stations, military barracks, custom houses, and so forth, the railway companies screened their stations, and the landowners and the peasants themselves followed suit. However, the results of these efforts were disappointing. It was soon recognized that even those persons who took care to keep their window screens in place and their screens closed—as many did not—were bitten by mosquitoes while performing their daily tasks out of doors. The screens enjoyed only a brief popularity and have now been generally abandoned.

Finally, through the efforts of Prof. Ceili, director of the Hygienic Institute at the University of Rome, the government turned its attention to quinine. The value of this drug in the treatment of malaria had, of course, long been known, but its cost placed it beyond the reach of the rural peasantry. The government decided to manufacture its own quinine and sell it at cost price. This step was followed by the passage of laws requiring the local authorities to distribute quinine free to peasants attacked by malaria, and the same obligation was imposed upon public contractors with respect to their laborers. Later the law was given greater scope, and the contractors were required to furnish free quinine not only to a remedy, but also, as a preventive whenever conditions appeared to warrant its use. The effect of these laws has been to reduce the mortality from malaria to a very small extent, but the disease is still a serious problem.

## SCIENTIFIC AMERICAN HANDBOOK OF TRAVEL

*With Hints for the Ocean Voyage for European  
Tours and a Practical Guide to London and Paris*

By ALBERT A. HOPKINS, Editor of Scientific American Reference Book

At last the ideal guide, the result of twenty years of study and travel, is completed. It is endorsed by every steamship and railroad company in Europe. To those who are not planning a trip it is equally informing. Send for illustrated circular containing one hundred questions out of 2,500 this book will answer. It is mailed free and will give some kind of an idea of the contents of this unique book, which should be in the hands of all readers of the Scientific American. It tells you exactly what you wish to know about a trip abroad and the ocean voyage.

**WHAT THE BOOK CONTAINS**

*The Sea and Its Navigation*  
Statistical Information  
Automobiles in Europe  
400 Tours, with prices  
Practical Guide to London  
Practical Guide to Paris  
Names 2,000 Hotels, with prices

**500 ILLUSTRATIONS**  
9 Color Plates  
9 Maps to pocket  
All About Ships  
Ocean Records

**500 PAGES, 500 ILLUSTRATIONS**  
**FLEXIBLE COVER, \$2.00—FULL**  
**LEATHER \$2.50 POSTPAID**

MUNN & CO., Inc., Publishers, 361 Broadway, New York City

### JUST PUBLISHED

## SCIENTIFIC AMERICAN REFERENCE BOOK EDITION OF 1913

It contains 600 pages and 1000 illustrations, is approximately bound in cloth and never before carried a special double price in any other edition.

Albert A. Hopkins  
Compiler and Editor for Part I, Sta-  
tistical Information, Editor of  
the Scientific American Handbook  
of Travel, etc., Member of the  
American Statistical Association.

A. Russell Bond  
Compiler and Editor for Part II, Sci-  
entific Information, Editor of  
Handyman's Workshop and Labor-  
atory.

The editorial staff of the Scientific American receives annually over fifteen thousand inquiries covering a wide range of topics—no field of human achievement or natural phenomena is neglected. The information sought for in many cases cannot be readily found in text books or works of reference. In order to supply this knowledge in concise and reliable form, two of the Editors of the Scientific American have, with the assistance of trained statisticians, prepared a *Scientific Reference Book*, containing over seventy-five thousand facts, and illustrated by one thousand engravings, for which the entire world has been scanned. Immense masses of government material have been digested with painstaking care with the collaboration of government officials of the highest rank, including cabinet officers, and checked by competent professors of world-wide reputation.

Owing to the printing of an edition of 10,000 copies, we are enabled to offer this book at a merely nominal price. The purchase of the book is the only adequate way to judge of its merits. An elaborate circular, showing specimens of illustrations, together with four full-size sample pages, will be sent on request.

**Part I**  
**STATISTICAL INFORMATION.**  
110  
Chapter I  
POPULATION AND SOCIAL  
STATISTICS  
(Chapter II)  
FARMER, FISHERY AND FOREST.  
Chapter III  
MINES AND QUARRIES  
Chapter IV  
MANUFACTURES  
(Chapter V)  
LOANING  
Chapter VI  
MERCHANT MARINE  
Chapter VII  
RAILROADS

**Part II**  
**SCIENTIFIC INFORMATION.**  
110  
Chapter I  
CERAMICS  
Chapter II  
ASTRONOMY AND TIME  
Chapter III  
METEOROLOGY  
Chapter IV  
MACHINERY, ELEMENTS AND  
MECHANICAL MOTES  
Chapter V  
GEOMETRICAL CONSTRUCTION  
Chapter VI  
WEIGHTS AND MEASURES

## The Scientific American Cyclopedia of Formulas

*The Most Complete and Authoritative Book of Receipts Published*

\*The Scientific American Cyclopedia of Receipts, Notes and Queries  
Edited by ALBERT A. HOPKINS, Query Editor of the Scientific American

THIS is practically a new book and has called for the work of a corps of specialists for more than two years. Over 15,000 of the most useful formulas and processes, carefully selected from a collection of nearly 150,000, are contained in this most valuable volume, nearly every branch of the useful arts being represented. Never before has such a large collection of really valuable formulas, useful to everyone, been offered to the public. The formulas are classified and arranged into chapters containing related subjects, while a complete index, made by professional librarians, renders it easy to find any formula desired.

**"As Indispensable as a Dictionary and More Useful"**

- Following is a List of the Chapters:*
- I. Accidents and Emergencies
  - II. Agriculture
  - III. Alloys and Aluminates
  - IV. Art and Artists' Materials
  - V. Beverages Non-Alcoholic and Alcoholic
  - VI. Cleaning, Bleaching, Restoring and Preserving
  - VII. Cosmetics, Colors, Pastes and Medicines
  - VIII. Coloring of Metals, Bronzing, etc.
  - IX. Dyeing
  - X. Electroplating and Coating of Metals
  - XI. Waxes
  - XII. Treatment of Metals
  - XIII. Household Furnishings
  - XIV. Ink, Cans and Condensers
  - XV. Insulation, Extractions of Varnishes
  - XVI. Lacquers, Oils, Resins, Ivory, etc.
  - XVII. Leather
  - XVIII. Lubricants
  - XIX. Paints, Varnishes, etc.
  - XX. Paper, Printing, etc.
  - XXI. Preserving, Cooking, Pickling, etc.
  - XXII. Rubber, Gums, Resins and Cellulose
  - XXIII. Stains and Cleaners
  - XXIV. Substances
  - XXV. Tannin Preparations, including Leather
  - XXVI. Watercoloring and Stenciling
  - XXVII. Waxes
  - XXVIII. Miscellaneous Formulas and Household Hints

SEND FOR DETAILED ILLUSTRATED PROSPECTUS

Circulars (4x6x1/2 inches), 1,077 Pages, 300 Illustrations  
Price, in Cloth, \$5.00; Net, Half Morocco, \$6.50; Net, Postpaid

MUNN & CO., Inc., Publishers, 361 Broadway, New York City

VERY COLLECTOR IN AMERICA WILL BE INTERESTED IN THE SERIES OF ARTICLES APPEARING EACH MONTH IN THE PAGES OF THIS MAGAZINE, ARTICLES UPON SUBJECTS WHICH WILL PROVE A DELIGHT TO AMERICAN COLLECTORS

## AMERICAN HOMES

### AND GARDENS

(For sale by all newsdealers. 25 cents a copy, \$3 a year)

WELCOME CORRESPONDENTS AND LETTERS OF INQUIRY FROM ITS READERS ON ALL SUBJECTS CONNECTED WITH COLLECTING OLD FURNITURE, POTTERY AND PORCELAIN SAMPLERS, FRAYS, SHAWLWORK AND TEXTILES, GLASS, FABRICS, BEANS, PENTERS, SILVER, OLD JEWELRY, COINS, MEDALS, MINIATURES, IN FACT WITH ANYTHING APPROPRIATE TO THE AMERICAN COLLECTOR. THE EDITOR OF THE "COLLECTOR'S DEPARTMENT" WILL BE GLAD TO FURNISH INFORMATION ON ANY SUBJECT CONNECTED WITH COLLECTING. INQUIRIES SHOULD BE ACCOMPANIED BY STAMPS FOR REPLY. ANY PHOTOGRAPHS OF SUBJECTS ACCOMPANYING LETTERS WILL BE RETURNED TO SENDERS IF REQUESTED.

THIS MAGAZINE GIVES SPECIAL ATTENTION IN EVERY ISSUE TO THE FOLLOWING SUBJECTS.

HOUSES AND HOME PLANT—GARDENS AND GARDENING—FURNISHING AND DECORATING—ANTIQUES AND CURIOS—COLLECTOR'S MART—HELPS TO THE HOUSEWIFE

Every successive issue emphasizes the fact that it is unsurpassed in its field for attractiveness and constructive value to all interested in Home making

SIXTY-NINTH YEAR

# SCIENTIFIC AMERICAN

THE WEEKLY JOURNAL OF PRACTICAL INFORMATION

Volume 57

NEW YORK, MAY 31, 1913.

PRICE 10 CENTS  
\$3.00 A YEAR

It is proposed to carry a large part of the sewage by a tunnel 10 feet in diameter under the lower bay to an artificial island three miles offshore, where the solids will be removed and taken out to sea in tank steamers and the liquids will be rendered harmless before being discharged.

**PLAN FOR THE DISPOSAL OF NEW YORK'S SEWAGE.—(See page 494.)**

The combined subscription rates and rates for foreign countries including Canada will be furnished upon application.

Remit by postal or express money order bank draft or check

**Munn & Co., Inc., 361 Broadway, New York**

The Editor is always glad to receive for examination illustrations or articles on subjects of timely interest. If the photographs are sent by the author and the facts outside the contributions will receive special attention. Accepted articles will be paid for at regular rates.

The purpose of this journal is to record accurately, simply and interestingly, the world's progress in scientific knowledge and industrial achievement.

## Science and the Cost of Living

WE are well accustomed to the notion that all science ultimately finds practical application. But we do not always equally realize that all practice has a scientific basis. Approach the average business man on the subject of the theory of wealth, and he is probably wary, but on the statement that he is too busy with the practice of producing value to pay much attention to theories, however pretty.

This may be all very well for many purposes, especially in those and rank of things often almost well enough. But in a position of industrial importance we can not afford to proceed by cut and try methods when science clearly points the way to him who will listen.

Everyone is keenly interested in the phenomenal rise in the cost of living which has taken place within the last six years—a rise of no less than 70 per cent. And so everyone deems himself qualified to account for the phenomenon. Each naturally sees the cause of the condition in some circumstance that happens to be the pet revelation, the tariff, the traffic troubles, under the introduction of machinery, or whatever it may be.

The fallacy of some of these attempts at explaining the situation is perfectly obvious to one who has made an unbiased study of the facts. The tariff can evidently not be the cause of a condition which has been observed equally in England, France, Germany and elsewhere as well as in our own country, as is clearly shown by Prof. J. P. Norton in an article "The Changing Cost of Living," in this week's issue of *SCIENTIFIC AMERICAN*.

As a matter of fact, the theory of currency furnishes an explanation which is as simple as it is convincing. Yet few people had, until recently taken note of this simple truth. It was first pointed out by Samuel Newcomb, that the purchasing power of an ounce of gold (supposing for the sake of simplicity that all purchases are made in gold) depends on two factors, first, the total amount of gold in circulation, and secondly, the rapidity of circulation. To quote J. D. Mar ("The Science of Money"). Suppose that 10,000 million dollars worth of exchange are to be transacted in a year, and suppose the only kind of money to be used consists of gold dollars. If these dollars could be used but once during the year, it follows that it would take 10,000 millions of them to effect the exchange. If they could be used and re-used fifty times a year (100 millions of them would suffice to effect the exchange," that is to say, the purchasing power of the ounce of gold would be fifty times greater than in the preceding year).

If, then, the purchasing power of gold thus depends on these two factors, the total amount of gold in circulation and the rapidity of circulation, we must expect that any marked change in either of these factors will be accompanied by a corresponding change in the price of commodities. The rapidity of circulation is subject to reasonable fluctuations, owing to the effects of the seasons upon trade and agriculture and the "price of money" fluctuates accordingly. Again, the total amount of gold in circulation has been, increasing steadily for many years, as the output of the world's

gold mines is many times greater than the loss of gold incidental to commerce and industry. This must necessarily bring in its train a fall in the purchasing power of gold, or, what amounts to the same thing, a rise in the cost of living, all the world over. No local legislation of any kind can possibly stem the tide, any more than we can hope by man-made laws to overcome the action of gravitation.

The fact that this simple fundamental law of the theory of currency was discovered by an astronomer and mathematician, and remained unnoticed by the bulk of "economists" for some twenty years, until unearthed and brought into the light by Prof. Kemmerer and Irving Fisher, carries a moral of its own. The non-mathematical is often inclined to consider somewhat flippancy of the formulae of the mathematician. No more was ever more utterly misplaced than this. No problem can be said to be completely solved until it has been cast into mathematical form. And many a "seton" life controversy rages for years, simply because the contestants have not sufficient mathematical judgment and training to count the number of variables involved in a problem, and the number of independent equations connecting such variables. No long as the former is the case, the problem, whether it be mathematical or industrial, and there are a number of possible solutions. A number of persons who, unaware of this, each insist on a solution of his own selecting, may evidently go on arguing forever without coming to an agreement. It is not apt to occur in a branch of science where the mathematical method of treatment is neglected or even despised.

## Cold Light

THE invention of Prof. C. F. Dumas, described and illustrated on another page in this issue, has more strongly attracted attention to our present methods of illumination. Between the glow worm and the incandescent lamp there yawns a gap which will some day be bridged by the combined aid of the physicist, chemist, engineer, and metallurgist. The luminous creatures of nature considered as lighting machines, viewed, at whatever distance, as objects of great interest. The best incandescent lamp of the day has an efficiency of about two per cent. In other words, we have still much to learn from the firefly.

It is only within the last few years that this problem has been systematically attacked. At least a score of highly trained scientists on the side of the ocean alone have applied themselves to the task of improving our methods of illumination. The new profession of "illumination engineering" has been created—a calling which is being filled by men who have the gift of distributing light most effectively. Psychologists, even, have been recruited in the effort to provide us with cheap and satisfactory artificial light for it is now recognized that much of the world's work is done at midnight and that the human eye, most delicate and responsive organ of the entire body, cannot be recklessly overtaxed.

In this systematic study of illumination much has been discovered which has encouraged the laboratory workers. A spectroscopic study of the firefly's light by Drs. Free and Coleman, along the lines long laid down by Langley, has shown that the intermittent flashes of the insect are spectroscopically akin to the radiation of the mercury vapor arc. Both lights are greenish yellow, or yellowish green. Of all the radiations in the spectrum the yellowish green radiation is luminously most efficient. Hence the mercury arc in a sense is a continuously glowing artificial firefly of glass and mercury vapor, and hence man has been unwittingly following in nature's footsteps.

Accepting as this is, let us take a light as cold as a luminous insect's will ever be really attained. Indeed, it may be doubted if we want the artificial equivalent of a firefly. Because the mercury arc radiation is decidedly unpleasant a scientific firefly's luminosity would be most agreeable. It is absolutely certain that light must be white, that it must not interfere too seriously with the judging of color values. Hence a slavish imitation of the firefly, a mere striving after a cheap and efficient light without regard to aesthetic requirements, will be fruitless. It seems inevitable that for this reason alone, best must always be an attendant of light.

## The Embroidery of Knowledge

ONLY one who has lived much among old books realizes the pathetic poverty of contemporary scholarship compared with the scholarship of some generations ago. Two criteria appear to be all-sufficient in determining what we shall learn nowadays, whether it be of old school. First, is it useful? Second, is it true? Once there was a third. Is it beautiful? Or, to express more completely the ideals of our grandfathers: Is it picturesque, quaint, romantic, colorful, spiritually ennobling?

As to what constitutes utility, opinions will always

differ, but between truth and falsehood the line is sharply drawn. Now, the ultimate criterion being the happiness of the human race, is there not much truth that is not useful to the world? In all ages there have been ascetic schools of thought that returned a formal negative to this inquiry, and modern pedagogy appears to have tended toward the same view.

More years ago than we care to specify, we learned the conventional story. Even then the fashion of putting mythical figures on the stage made a forlorn effort of teaching mythology along with astronomy—was on the wane, but by a chance, for which we have never seemed to be thankful, old Burritt fell into our hands. We learned the story—and how much learned! How much, however, is often inclined to be a point—was aimed at—of which the modern youth commonly learns nothing. All more embroidery, if you like—but how beautiful, how entrancing, how well worth cherishing through life! Old Orion brandishing his club at the Bull, the midwife sedately pacing around the patient, the careless of the Hunting Dogs at his heels, the jeweled locks of Bernice, the Swan soaring down the Galaxy, and all the rest of that splendid company that still, for us, people the nightly sky, but is invisible to many astronomical observers. How many of the "useful" numbers and other "right" and "useful" things? Of course, one can and does learn mythology without the stars—whether from the fountain-head in Homer and Hesiod and Ovid, or from some short-cut of modern derivation—but how much the myths and the stars enhance each other, and how much the more the more is losing in their conjoined appeal!

And so of the flowers, their legendry, their embroidery, is even more comprehensively neglected than that of the stars. What modern teacher of botany thinks it necessary or expedient to teach his class the history of herb-lore—to show them copies of the old herbaria—to explain the quaint doctrine of "magnatures"? What does the youth of to-day know of the curious beliefs enshrined in scores of familiar plant names? To be sure, some knowledge, like a knowledge of star-lore, is absolutely essential to an understanding of thousands of allusions in world literature—in Shakespeare, Dante, Tennyson, Keats—and hence to a full enjoyment of such literature, but apparently this fact does not make it "useful" according to Philistine standards.

As to history, happy is he who learned picturesque fables along with sober truths from Goldsmith's histories of Greece and Rome. We fear hardly a school boy of the present generation (apart from the dwindled few who still know Latin) has ever heard of that maid, on a certain memorable occasion, "Strike, but hear me!" or has ever so much as heard what summer Leontidas made to the Persian monarch when summoned to deliver up the Spartan arms at Thermopylae. You who know only jejune matters-of-fact modern textbooks and reference books—open an afternoon in some old library, with Rees's Cyclopaedia and the Oxford, with Lempriere's Classical Dictionary ("readable if not very trustworthy" the Britannica calls it), with a score of old books on "natural history" and "natural philosophy", and, above all, with some files of the old periodicals. You cannot fail to be impressed with the fact that, with all its intellectual and material gains, scholarship has lost much in grace and distinction and humanity. What is more remarkable—and here is a hint for the teacher of the sciences—is that the old books contain an astonishing amount of substantial and authentic information that has, somehow, dropped out of sight in the hurly burly of "progress."

## Hereditary Effect of X-Rays

EXPERIMENTS in exposing X-rays to the ovaries of animals have shown that they are extremely sensitive to the rays, and are modified more strongly than is seen in any other tissue. Recent researches made by M. Fraenkel in Germany appear to show that such modifications are transmitted to the next generation, and we are now aware of several instances in this case. He applied the rays for half an hour upon a four-day old female guinea pig, and found that in the subsequent growth of the animal the development in size and weight are strikingly lessened as compared with specimens, 170 generations as against 725 at the age of 10 weeks. However, the reproductive capacity is not diminished, and the female gave birth (after the normal period of 9 weeks) or at the age of 30 weeks, to three young, one dead and two living, but strange to say, the young had an extremely small size and bore a marked resemblance during their growth. Again the reproductive power is not lessened. These animals were not exposed to the rays. The female having 7 inches length, gave birth to two young, one dead and the second of extreme weakness and weakness, and another healthy young. During the second litter of three young, but all very small, after which she could no longer reproduce, the organs, altered by the X-rays, failed to give their vitality again.

## Engineering

**The New German Drednought "Grosser Kurier"**—was launched at Hamburg on May 5th. This vessel is a *decksailer* of the "König," launched March 1st. The new drednought has a displacement of 27,000 tons, and will be armed with ten 14-inch guns.

**Upton's Challenge for "America's" Cup Accepted**—The challenge of Sir Thomas Upton, of the Royal Ulster Yacht Club, has been accepted by the New York Yacht Club. The races are to take place under the New York Yacht Club's present rules of measurement, time allowance and racing, in September, 1911.

**British Gun Record**—It is reported that the British super-drednought "King George V" has made a record of 30 hits out of 40 rounds fired with its 13.5-inch gun. The American record for big guns is held by the battleship "South Carolina," which in 1910 made 54 hits out of 57 shots with 12-inch guns. This is a record of 97 per cent, as against 97.4 per cent of the "King George V." No information as yet is available as to the range under which the British record was made.

**Nine Years of Work on the Panama Canal**—A report has recently been published marking the completion of nine years of work at the Panama under American jurisdiction. Little actual work was done for the first three years. Now 90 per cent of the concrete work has been completed, and only 20,000 cubic yards of dirt are still to be excavated. The total expenditure so far does not exceed \$20,000,000. Expenses are now proceeding at the rate of 2,500,000 cubic yards per month.

**To Deepen the Butterfield Channel**—In order to provide adequate access to the New York Navy Yard, the Government has decided to deepen the Butterfield Channel between Governors Island and the Brooklyn shore to 40 feet, and increase its width to 1,000 feet. At present it is supposed to dredge it to a depth of 35 feet, which will cost \$1,900,000. Later 5 feet more will be excavated, at a cost of \$3,300,000. The reason for favoring this route, instead of the one now in use around the northwestern end of Governors Island, is that the latter would involve the removal of two rock ledges, which would be a difficult and dangerous task owing to the congested condition of shipping at this point. This deeper channel is called for by the increasing draft of our dreadnoughts.

**Opening the Pacific End of the Panama Canal**—The ditch south of the Miraflores locks has been kept the way of Ancon Harbor out of the Panama Canal during excavation, was destroyed by a blast of 32,750 pounds of dynamite on May 18th. This left the way of the Pacific into the canal. It was originally planned to continue the canal back of the ditch with the latter would be the dredges at the Pacific entrance had practically completed their work they were available for operation in the canal itself. The ditch was accordingly ordered to admit them. As excavation with dredges is more expeditious than steam-shovel work, this will make for increased progress. Although the canal will not be officially opened until January 1st, 1915, it is probable that ships will be able to make the passage through it early this fall. The only element of uncertainty is due to the slides at Curran. Were it not for these slides there would now be only a million and a half cubic yards to be taken out of the cut instead of six and one half million cubic yards.

**Naval Fire Control**—The daily press has been thrown into a high state of excitement over the theft, last March, of the fire-control plans of the dreadnought "Prinzess Alice," holding that vital secrets have been stolen to be sold to a hostile power. Secretary Daniels' statement that these plans will be of practically no value to an enemy has failed to allay the excitement. The following reasons for considering the matter of trivial importance are given by Capt. William P. Sims, of the U. S. Navy, in a letter to the New York Times:

1. "As a matter of ordinary every-day common sense, there are no wholly essential fire-control instruments or wiring in any battleships in the world that are not below the protective deck, under water, and behind very heavy armor."

2. "All the exposed wires on the masts and elsewhere are made of fire control, but are in no sense essential. They are for the purpose of facilitating and accelerating the transmission of orders, which can be given, however, by men with nearly equal efficiency without them."

3. "The wires necessarily extend nearly the entire length of the vessel, so that there can be no special vital point for the enemy to attack."

4. "There are not and never can be, marksmen possessing such supernatural powers as to be able (with much information) quickly to direct a shot that would disable a ship and make it impossible for her to direct her fire."

5. "Upon supposing the machines to be entirely accurate in their aiming, and the fire-control officers to be equally accurate in their estimate of the distance, the speed and course of the enemy, the effect of wind, etc., there are no guns (including the powder, shot, rigidity of support, accuracy of sights, etc.) that are so infallible as such a scheme of precision in shooting at battle ranges, that 10,000 shots of 15-inch guns would not hit 10,000 targets."

## Electricity

**Power Plants on the Water**—Quite an extensive scheme is on foot to use water-power from the Weiser and other streams so as to operate three electric stations and distribute current over an area of 2,500 square miles, resulting in a production of 600,000 kilowatts of the enterprise figures at \$2,000,000 and over. Dams are to be erected across the streams at Eder, Menden, and Hellinghausen for supplying the three turbine plants at these points, and all these plants together with their substations will be later connected upon the same network of power lines.

**Turning a Sewer Into a Passenger Subway**—A somewhat unique example of a "subway" electric line is found in the Paris sewers. Here the tunnels are of unusually large size and, as is well known, they afford a considerable passage, carrying large water and gas piping on roof and sides as well as electric cables of various kinds. A recent idea has been to install a small electric road in one part of the tunnel so as to carry men and material. The miniature cars are drawn by a front motor car which works by a trolley from a pair of wires run along the ceiling, and quite a train of the small cars is taken in this way.

**Electrication of the Berlin City Belt**—The Prussian Minister of Public Works, Herr von Breitenbach, expresses himself in favor of the proposed electrification of the Berlin city belt and suburban railways, for the traffic would be increased, and the time within which the system, and steam traction is no longer adequate to handle the traffic. Electric drive would give practically double the number of trains per hour, besides securing all the well-known advantages of the electric system. The Prussian Parliament recently voted a credit of \$6,000,000 for carrying on preparatory work upon this important scheme.

**Railroad Time by Wireless**—The North Railroad Company of France uses the Eiffel Tower wireless time signals in setting its station clocks at Amiens and Boulogne and the important center of Reims. The new system is superior to that of the telegraph, besides it does not temporarily monopolize telegraph lines. Each day at 10:45 A. M. the employees at the small wireless post of the depot receives the tower signal and regulates his clocks accordingly. From this clock the time of the premises are regulated. A new portable wireless receiver contained in a small box is specially designed for taking the tower signal, two wires stretched between telegraph poles serve as antennae.

**Advances of a Generator**—From some unknown cause, the dynamo of a steam-turbine group blew up in the Essex station and made considerable havoc on the premises. The group in question consisted of a Zoelly steam turbine working at 1,000 revolutions per minute and direct coupled to a 5,000-kilowatt alternator. The whole machine burst, throwing pieces in all directions, one piece weighing several tons went through the wall and damaged an adjoining building. Other heavy pieces of 2,000 pounds weight were thrown through the roof, while the dynamo room was scattered with fragments. All the machinery had to be broken down to be hauled out and not to the machines of the plant. No one was injured, fortunately.

**Stephen Dudley Field, known as the "father of the trolley,"** died at his home in Brookbridge, Mass., on May 18th, at the age of 67. He was the nephew of Cyrus W. Field, who laid the first Atlantic cable. His first work with the electric car was in 1880 when he built an experimental line on his own grounds in Brookbridge. His car took current from a central third rail. He also took out patents on conduit and trolley systems. One of his first inventions was the hoist arrangement, the first one of which was installed in the Palace Hotel, San Francisco, in the early sixties. In 1874 he produced the multiple rail district telegraph car, and in 1879 created a revolution in telegraphy by the introduction of the duplex system. The following year he developed the quadruplex telegraph, and in 1890 he applied his system to the cable between Key West and Havana. He was also active as a pioneer in long-distance telephony and electric lighting.

**Perkowitz, a New Artificial Potash Fertilizer**—A Swedish chemist, Perkowitz, and Lindblad, one of the constructors of the Troilstein furnaces for the manufacture of nitrate, has just succeeded in producing a new artificial fertilizer which is capable of replacing the Russian salts which are at present imported into Sweden at an annual cost of about \$2,000,000. It is obtained by treating feldspar or some other mineral having a potash base in an electric furnace, together with suitable quantities of carbon and iron. The resultant products are ferro-silicates, which can be used as fertilizers, and a potash and a phosphate, which are readily soluble in water. To prepare the latter for use it is only necessary to crush it in a suitable mill and there it is. Experiment proves that it is readily assimilable in all soils. It possesses the advantages over Russian salts that it contains no objectionable, which are said to be injurious in some soils. It is also recommended for use in the manufacture of salts of potassium and aluminum.

## Aeronautics

**A Record Altiplane Flight with Six Passengers**—On May 8th, at Chartres, France, aviator Francou carried six passengers in his biplane for an hour and a quarter in a heavy biplane. During the flight he rose to an elevation of 2,500 feet, which is a far greater height than has been reached before by a machine carrying so many passengers. The duration of the flight also constitutes a new record.

**A New Flying Boat Record by Naval Aviators**—On the 9th inst., a new endurance record was made by Lieut. J. H. Fowers and Ensign G. de C. Chevalier in a Curtiss flying boat. Starting from Washington, they followed the Potomac River and Chesapeake Bay to Annapolis, 100 miles away. Three hours and five minutes were consumed in making this flight and the machine was kept at an average altitude of 1,000 feet.

**A Flight with Passenger from Bremen to London**—On Sunday, the 11th inst., M. Brindeau des Moulins flew from Bremen to London—a distance of about 450 miles—at a high speed. He left Bremen at 8:40 A. M. on May 9th, and flew to Calais. The flight from the French port was made on the afternoon of May 11th. M. des Moulins rose to a height of 5,000 feet and crossed the Channel in twenty minutes, which is a record. From Dover to London he maintained a speed of 1,000 ft. per hour. He flew directly over the city, despite the regulations to the contrary, and landed at Hendon aerodrome at 3 P. M.; thus again demonstrating the facility with which one can travel by aeroplane from country to country, despite all rules and regulations forbidding the same. A few days later M. des Moulins was hailed to court and fined for having flown over London.

**A Record Flight Across the Alps**—For the third time the Alps were crossed on the 13th inst. by an aeroplane. In this case, however, it was the Herise Aviateur which was flown over by Oscar Hider, the Herise aviator in his monoplane. Starting from Oberstdorf in the canton of Berne, Switzerland, Hider flew until he reached a high elevation and then flew directly across the Raviel Pass at a height of 4,200 meters (10,400 ft.). He was two and one quarter hours flying the flight. He was accompanied by a second aviator, Valais. Practically the entire flight was above the snow-covered mountains and glaciers and Hider was so cold and exhausted at the finish that friends had to lift him from his machine. The entire flight, including the alighting at the race, was made without any mishap.

**An Oversea Aeroplane Race from Key West to Havana**—For a prize of \$10,000 offered by the Cuban government, two Cuban aviators attempted to fly from Key West to Havana, a distance of about 100 miles on May 17th. Despite a strong wind, Domingo Basile started at 6:35 A. M. in a Moisant monoplane and successfully accomplished the flight in an hour and a half. He flew over the city for another quarter of an hour before he alighted. His machine was not provided with floats and the flight was one of the most daring ever reported. A Cuban cruiser and two gunboats patrolled the course and were stationed some twenty miles apart. Raul's competitor, Augustine Pina, was unable to start in his Curtiss hydro-aeroplane because of some damage to the machine, but two days later he also made the flight. The flight was the first of several recent flights of this kind, which are given impetus by a new long-distance transatlantic flight by having stationed, on a designated line of latitude about three hundred miles apart, a series of floating life stations in communication by wireless telegraphy, by which the progress of such a flight could be reported and news given in case of accident.

**A Monomaniac in the Air**—An occurrence which seems incredible, but which is vouched for by three prominent French officers, is recounted in *Aeronautics*. This is nothing more or less than a somewhat in the air which befell Capt. Aubry when flying a Dérienne for the purpose of making a reconnaissance over the region of Villiers. "I was returning after a 45-minute flight," the Captain assures us, "facing a wind of about twenty-two miles per hour. My altitude was about 2,500 feet. At the moment of descent a series of violent gusts struck the machine, and on shutting down and switching off, I was obliged to drive in order to make the control effective. As I dipped the nose of the machine, a couple of quick, successive gusts struck the top of the main plane and placed me in a vertical position. While still in this position I was obliged to shut down the machine had taken me in a perfectly vertical chute to less than 1,500 feet. It here adopted a horizontal attitude upside down and proceeded to effect a tail-rift 'no place'." Somehow the pilot retained his consciousness. "The machine," he continues, "gradually took up the vertical position again describing a gigantic '8' while doing so. Flattening out, I flew to a spot about two miles distant."

# A Hydraulic Variable Speed Gear

## A Power Transmission Mechanism Consisting of a Pump and Engine Couple

SEVERAL years ago a new type of speed gear was experimentally installed on one of our battleships for controlling the elevation of a 12-inch gun. The gear proved so successful that more than five hundred of these machines are being used by the United States Navy. For a while the speed gear was kept quiet, but eventually the news leaked out, and the machines were sought by European powers as well. Now they are being built in England, France, Russia, Italy and Japan. Broadly, the gear consists of two main parts, an oil pump, and an oil engine operated by the fluid set in motion by the pump. The speed of the oil pump is constant, but the stroke of its pistons may be varied at will thus varying the flow of oil to the engine and correspondingly varying the speed of the oil engine. The stroke of the piston is varied by operating a control shaft, and because the fluid used is practically incompressible and the leakage between pump and engine is on the average 15/100 of one per cent, the speed ratio between the pump and engine is positive and definitely determined by the angular position of the control shaft regardless of the amount of power that is being transmitted.

The operation of the gear may be understood by referring to the accompanying drawings showing a sectional plan and a sectional elevation of the gear. The pump end of the gear is marked with the letter A, while the engine end is marked B. Accordingly, the A shaft is the driving shaft, while the driven shaft B is at the opposite end. The entire gear is inclosed in an oil tight casing, and is provided with an oil expansion box 1. With in the casing two chambers are formed by a partition 2, known as a valve plate, at the 4 end of the casing is a tilting box 4, in which is mounted a socket ring 4. The box 4 does not revolve, but serves as a guide for the ring 4, giving it a wabbling or gyratory motion as it is carried around by the shaft A. The amount of the gyratory motion can be varied by tilting the box 4. A series of nine pistons 5 are connected to the socket ring 4 and are made to play in and out of the cylinders 6, as the ring 4 gyrates. Of course the cylinder barrel 6 revolves with the shaft A. It will be evident that the stroke of the pistons 5 will depend upon the angle of inclination of the box 8. If the pistons of the box 8 are normal to the shaft A there will be no gyration of the ring 4, and consequently no reciprocation of the pistons, and if the box is tilted past the normal the pumping will be reversed.

The engine mechanism at the opposite end of the gear is quite similar to the pumping mechanism, except that in place of a tilting box there is a box 7 set at a fixed angle equal to the maximum angle of inclination of the box 8. Mounted to turn in the box 7 is a socket ring 7, connected with a series of pistons 9, that operate in the cylinders 10. The cylinders 10 at the pump end are supplied with oil from the cylinders 6, through ports 11 in the valve plate 2. It will be evident that as half of the pistons 5 are moving inward the other half are moving outward, so that when the gear is transmitting power one of the passages 11 is under pressure, while the other is in suction. If the angle of inclination of the box 3 is equal to that of the box 7, the engine cylinders 10 will be filled and emptied at single stroke of the opposite pump pistons 5. As the engine cylinders are filled and emptied their pistons 9 are reciprocated and as they push the inclined ring 8 against the box 7 cause the ring to revolve and carry with it the shaft B. Thus the power transmitted from the A to the B shaft will undergo no change of speed. However, as the control shaft 12 is operated to tilt the box 8 more and more toward the vertical position, the stroke of the pistons 5 will be reduced and it will take more than one stroke of a piston

5 to move a corresponding piston 9 out to its full extent. Thus the shaft A will have to make more revolutions than the shaft B, and the ratio will increase as the control shaft is operated, until the box 8 is moved to vertical position, when the stroke of the pistons 5 will be reduced to zero, and the shaft B will remain stationary, although the shaft A is still running at constant speed. If the control shaft 12 is still further

the motion of the shaft B. The oil within the casing of the gear is under no pressure, but merely serves to lubricate the parts. The only pressure that which exists between the pump and engine cylinders, and the design is such that there is practically no leakage between the cylinder barrels and the valve plate 9 except enough to provide a lubricating film. The socket rings 4 and 8 are mounted on roller bearings in the respective boxes 1 and 7, so that the gear is practically frictionless.

The method of controlling the inclination of the box 8 by means of the control shaft 12 is illustrated in the photograph, which shows the parts of the gear removed from the casing and separated. The box 8 is formed with an arm which carries a sliding nut engaging a threaded extension of the control shaft 12. Turning the shaft 12 results in moving the arm up or down, and thereby tilting the box 8, which has pivotal connection with the casing.

The chief advantage of this type of transmission is its great flexibility. The B shaft may be started under a dead load of any magnitude within the strength limits of the machine, without any fear of overloading the motor or source of power, the speed may then be increased gradually and positively to its maximum without stops or abrupt gradations. Its remarkable flexibility must necessarily give wide differences of efficiency. Under the best conditions efficiencies ranging from 65 per cent to 91 per cent are common; under average working conditions the efficiencies vary between 80 and 85 per cent; under small loads and low speeds of the B shaft the efficiency may be 90 per cent down to 80 per cent or less. Of course at a zero speed the horse-power efficiency must be zero per cent, while the torque efficiency remains at 95 per cent, and so the horse-power efficiency has a wide range from zero per cent to 91 per cent, while the torque efficiencies throughout the whole range remain between 90 per cent and 95 per cent.

Aside from turret and gun control on battleships these hydraulic gears have been applied to automobiles, tram cars, drawbridges, cranes, hoists, machine tools, and the propelling of vessels. Indeed, the field of application seems as wide as the transmission of power at variable speeds.

### Preserving Cut Flowers

MODERN research in France has developed the art of preserving cut flowers to a point undreamed of a few years ago. The old way was to cut off the end of the flower stem or sear it or add salt water. Fourton and Ducomet applied the principles of osmotic pressure to the subject. They reasoned that when flowers containing salts in their juices were placed in pure water, the unequal pressure thereby developed ruptured the cell walls and made the plants wilt. Consequently they tried a great number of solutions for preserving the cut flowers and found that when the osmotic pressure of the solution outside equaled that of the juices in the flowers, the best results were obtained.

Sugar solutions of varying strength proved the most effective except in the case of lilies, lilacs and sweet peas. Carnations lasted longer in a fifteen per cent sugar solution, while roses were permanent in a sugar solution of half that strength. Chrysanthemums and tulips are not benefited, but effort is being made to discover a suitable preservative for them also. Although plants are not kept as long as the flowers, they are not kept as long as the flowers in the vase. One of the United States experiments has been conducted in this line and has been successful.

operated, the box 8 will be oppositely tilted and the pistons 5 will again begin to reciprocate, but those which were formerly moving inward at one side will now be moving outward. So that the port 11, which was formerly under compression, will now be under suction, and vice versa. This will result in reversing

the gear by a single rotation only, yet if they are put in a twelve per cent sugar solution which also contains one hundredth of one per cent potassium cyanide, they last much longer than usual and improve in look. One of the United States experiments has been conducted in this line and has been successful.

## Dussaud's "Cold Light"

Its Remarkable Applications

By Jacques Boyer

Fig. 3.—A searchlight to be used by firemen.

THE accompanying photographs are probably the first illustrations of the apparatus which has been invented by Prof. C. F. Dussaud, to produce what he calls "cold light." In a sense, the term "cold light" is not absolutely correct. Heat is necessary to produce light in Dussaud's apparatus, as it is in every other lamp, but the term is justified in so far as Dussaud's lamps radiate a negligible quantity of heat.

How this paradoxical result is obtained will be clear if we refer to the accompanying diagrams (Figs. 6a and 6b). The Dussaud system consists essentially of a series of tungsten-filament lamps *c*, mounted near the periphery of a wheel or disk composed of any suitable insulating substance and carried on an electrically insulated shaft *a* turning in a support *b*. A metallic pulley *e* is mounted on this electrically insulated shaft *a*, and the pulley is connected by a belt *f* with a crank or a small electric motor *d*. Each of the bulbs is fitted into a socket *g* secured on the disk and communicating with one of its poles, the other terminal being connected with the lamp-base *h*. The end of each lamp-base *h* engages a metallic ring *g*, mounted on the rear of the disk *a*, and connected by bars *k* with a plate *l*, adjacent to the metallic pulley *e*, against which a commutator brush *i* conducts, the brush being connected with one of the poles of the source of electricity. The other pole communicates with a commutator brush *j*, the contact point of which lies in the circumference of the circle described by the sockets *g*.

As the disk *a* is rotated by the motor *d*, all the lamps *c* are successively and intermittently lighted when they touch the commutator *j*, and are successively extinguished as soon as they leave it. As soon as one lamp moves away and is extinguished, another immediately takes its place and is illuminated, the retinal persistence of the intermittent flashes giving

Fig. 4.—A photograph of an interior taken by Dussaud's cold light.

Fig. 5.—A "cold light" moving picture projector, in which the film may be stopped without danger of ignition.

the effect of a steady light. Each lamp is supplied with current for such a very brief interval that the slight amount of heat to which it is subjected is very quickly dissipated. The cooling interval is about double that of the light interval. Dussaud has found that with this apparatus it is possible to "overload" his lamps, that is, he can impress upon them a voltage from two to four times above their normal. Hence the efficiency of the lamps is greatly increased and a very much more intense light is obtained from a given filament. The effect of overloading is remarkable. In a paper read before the Academy of Sciences by Brault, it is stated that with 50 to 100 watts applied to 16 lamps of 25 to 80 candles, Dussaud has respectively obtained 250 to 300 candles of cold light for several hours.

As our illustrations show, Dussaud employs an optical system with his lamps. In other words, other lenses or mirrors. The result is that while the heat effect of the electric current is dissipated over a great area, the luminous rays are concentrated in a very small point or space.

The tungsten lamps employed are of Dussaud's own design. Some of them are only 0.8 to 1.6 inches in radius. Groups of three are used in some models. They are successively flashed in the focus of a condensing lens, without breaking down the filament or blackening the bulb. Indeed, it is said that the results produced are identical with those obtained with an electric arc ten times more intense.

Dussaud's new light is particularly adaptable for use in situations where great luminosity must be obtained with a feeble current. These conditions, for example, are those which manufacturers of moving picture projectors have long tried to realize. Dussaud has shown that it is possible to project moving pictures on a sheet five yards square with an electro-generating apparatus of 150 watts, in

# Plans for the Disposal of New York's Sewage

## A Treatment Plant on an Artificial Island Three Miles Offshore

LOOKING out of the window of his office in the Whitehall Building, Dr. George A. Soper, president of the Metropolitan Sewerage Commission of New York, recently saw a man filling a barrel with water from the North River at the Battery. Sending one of his men out to learn what use was to be made of this water, he received the startling information that it was to be sent to a town in Vermont to furnish sea baths for a sick lady whose parents could not afford to take it to the seashore as directed by the family physician. The man was astonished to learn that his barrel was filled not with sea water, but with sewage! With many other people in this city, he shared the notion that all salt water is proof against disease and that even though the waters about New York may not appear very clean, they are perfectly harmless. Yet it has been demonstrated that typhoid germs live in salt water just as long as in fresh. They have actually been found to live in oysters for forty-three days, or as long as the shell could be kept alive.

Popular ignorance on questions of sea age and on the dangerous condition of New York Harbor is appalling. Free baths are used which, in many places, have been placed almost at the very mouths of large sewers. Many a bather has become ill through diseases caught from the filthy waters. In order to show how sewage water finds its way into these bathing places, strong dyes were recently placed in a sewer, and before long the waters of an adjacent municipal bath were so reddened as greatly to alarm bathers. The very first thing a bather does is to duck his head under and take in a mouthful of the water, in that way exposing himself to all imaginable forms of disease germs that infest those bathing places. Exactly how much disease results is difficult to determine, for the reason that those who patronize the baths live in disease-infested environments but the municipal authorities are now aware to the dangers and are considering plans for filtering the baths in which (rotten water or filtered sea water will be used.

There is no doubt that our ignorance of sewage conditions is due mainly to the fact that the subject is not a pleasant one to investigate. But conditions have grown so bad in this vicinity that the matter has been forced upon us. Several years ago the Legislature of New York State directed the city to appoint a commission to investigate the problem confronting New York city and offer suggestions as to the disposal of the city's sewage. The members of this commission who were selected by Mayor McClellan and reappointed by Mayor George A. Soper, the president, is a civil engineer who has also had wide experience in the management of epidemics. He is one of the few American members of the British Royal Sanitary Institute. He recently made an exhaustive study of subway ventilation and suggested many improvements that have been adopted and are now in force. Three other members of the commission are also engineers. James H. Fournier, a man of international reputation on questions of sewage disposal and water purification. Charles McClellan, father of culmen building foundation, H. de B. Parsons, Professor Emeritus of Practical Engineering at the Henssler Polytechnical School, Troy, N. Y. The fifth member, Lindsey B. Williams, is a physician with reputation who is considered for State Commissioner of Health.

The work of this representative body, while not yet complete has been disclosed in a number of preliminary reports which indicate that the problem has become a very serious one. Their study, their findings, entirely impartial and their suggestions are perfectly feasible from the engineering and sanitary standpoint. Their conclusions have been reached only after examining into the methods of handling the sewage problem in other cities in America and in

Europe, and consulting with eminent foreign experts in the fields of Chemistry, Engineering, Biology and Hygiene.

In their investigation of New York city conditions they found that the Harlem and the lower East River presented the worst conditions. Into the East River, in 1910, two hundred and sixty-four million gallons of sewage emptied every twenty-four hours. The sew-

that due to the tides. In order to study the direction and character of currents in New York Harbor, floats have been placed in various localities and records of their movements have been kept. One of these floats placed in the East River traveled in 75.5 hours 107.79 miles, at the end of which time it was picked up only a mile from the starting point. It seems so unlikely that sewage is carried back and forth by the river with little prospect of being carried out to sea. Every year the Department of Docks and Ferries dredges out about 400,000 cubic yards of deposits from the slips and docks of the lower East River, while in addition to this, large quantities are also dredged by private enterprises. One of the worst points in this section is Newtown Creek, which probably holds the world's record for filth. In Wallabout Bay a nine-foot sewer empties at the bulkhead line, in water that is so sheltered from the currents of the East River, that there can be no satisfactory dispersion of sewage. Even worse conditions are found outside of the lower East River section in Gowanus Canal, whose waters are black with filth, for the reason that nine sewers empty into the blind channel. In the hope of improving the canal a tunnel has been built, connecting it with the upper bay, through which the sewage water is pumped from time to time, but this has had little effect upon the canal and has not bettered matters, for the reason that the waters of the upper bay are already charged with far more sewage than they can take care of.

In considering the sewage problem of New York, it was found necessary to divide the city into sections, as indicated in the accompanying map. Tentatively, it is proposed that the sewage pouring out of Manhattan into the Hudson River be treated for the removal of solids and grease and then be allowed to discharge into the stream. The solids would have to be collected at some central point and burned, unless some use for the material was found. Similarly, the sewage from Richmond and from that part of Brooklyn facing the upper bay as well as from certain portions of the Bronx and Queens would be treated for the removal of solids. The most serious points, however, were the Harlem River and the lower East River. To take care of the sewage now emptying into the Harlem River, it is proposed that a sewage disposal plant be built on Ward's Island, which would receive all the sewage coming from the Bronx and the upper eastern side of Manhattan. The sewage here could be treated for the removal of the solids, the liquid being pumped into the upper East River, and the sludge carried off to sea in tank steamers. Another plant could be placed at Tailman's Island.

For the lower East River a plan has been proposed which at a first view may seem rather daring. It calls for the construction of an interceptor taking in the sewage from the lower east side of Manhattan, dipping under the East River, joining an interceptor on the Brooklyn shore and then passing on out under the lower bay to an artificial island built three miles offshore. This line would take most of the sewage now emptying into the lower East River. The lower bay would receive the sewage from the vicinity of Jamaica Bay. The tunnel would pass out to sea at a depth of about sixty feet.

The outlet island would be built on a shoal, which, judging from the surveys of the past thirty or seventy years, is practically permanent. There are no insuperable difficulties in the way of building the tunnel from the main line to the island, or of constructing the diggers under the East River. There are no sanitary obstacles that prevent themselves in the disposal of the sewage on the outlet island. Everything about the proposed plan is based upon present conditions. (Continued on page 491.)

Section through one of the proposed settling tanks.

Map showing New York's proposed sewage disposal system. Sewage from the shaded territory will be carried to the artificial island.

age came from territories in Manhattan, Queens, and Brooklyn, populated by 2,000,000 individuals. In the narrow Harlem River 80,000,000 gallons of sewage were received daily. The North River received only 150,000, 000 gallons of sewage daily from a population of 720,000 in Manhattan and 280,000 in New Jersey; the latter contributing 34,000,000. It is possible that the very fact of our calling these bodies of water "rivers" has led to the impression that they can handle any amount of sewage easily. The Harlem River is not a river, but merely a strait connecting the North and the East rivers. There is no actual flow in this strait except that produced by the tides. The East River is in no sense a river, but merely an arm of the sea, while even in the North River there is little flow except

## The Electrical Auctioneer

To the Editor of the SCIENTIFIC AMERICAN

In consequence of an article in your issue of April 20, page 371, on the "Electrical Auctioneer in Holland," I beg to inform you, that this system has been in application for several years in the auctions of vegetable at Delft and at Loosdrecht near The Hague, and with excellent results. It is perhaps known to you that these auctions supply Berlin with vegetables.

The Hague.

## The Dangerous Position of Aeroplane Motors

To the Editor of the SCIENTIFIC AMERICAN

The mad and unnecessary death of Lieut. Park in an army biplane near Los Angeles on May 10, brings those interested in aviation face to face more than with a fatal error in design which places the motor behind or beside the pilot's seat in aeroplanes. This has been demonstrated by a large share of the prejudice now existing among people, but they are not generally aware of the chief, the underlying cause of the deaths of several of the world's best aviators.

There are many cases so similar to that of Lieut. Park that a statement of the manner of his death will suffice to show that the placing of an engine in such a palpably dangerous position is little short of criminal. This is the opinion expressed by every aviator and mechanic with whom the writer has discussed the subject. It is a point which should be emphasized by the press and everyone interested in the future of aviation and the safety in design of flying machines of all types.

The writer has seen motors torn from beds to which they were often loosely fastened and literally hurled in the ground by their force of impact. The shock necessary to dislodge a two or three hundred pound mass of metal work, in many cases, is insufficient to bruise more than slightly the pilot of a machine were he not crushed by the motor. This has been demonstrated by the evidence to machines built with the heavy parts placed in front of the driver.

Hubert Latham was not even badly shaken up in a fall of a hundred and fifty feet which demolished a barbed wire fence, the landing chassis, propeller and one wing of his 1,400-pound Antoinette monoplane. The motor of his Los Angeles aviator met in 1910, the day before Howard Wilson was killed at the same meet. On the other hand, a well-known aviator told the writer of a fall in which he barely escaped death when his motor, placed a little to one side and at his rear, was dislodged and shot past him, making a hole two feet deep in a plowed field.

An eye witness of the accident to Lieut. Park says that the "tree" which wrecked his machine was only a bush, a fall from the top of which would probably not have injured anyone. The officer's head was horribly mangled by the heavy motor.

The flying machines of to-day are certainly an improvement over the earliest machines, but beyond a doubt they are faulty in many points. Many of these faults are difficult to remedy, but the present danger to the motor is certainly very easy of solution. More attention should be given by all designers to placing the motor in aeroplanes in such a position as to give the pilot this one insurance of safety at least.

Will every engineer in justice to the men who risk their lives for their country, alter the machine now in use and make the placing of the motor in front of the pilot one of the requirements for acceptance by the Government? This will cost little, surely not as much as the loss of men of Lieut. Park's caliber.

Pasadena, Cal.

WOODWARD F. BARNWELL

## BattleShip Protection for the Pacific Coast

To the Editor of the SCIENTIFIC AMERICAN

In your issue of October 12th, 1912, in an article on the last naval review in the Hudson River, the following appears:

"The great mobilization of the Atlantic fleet at New York, for inspection by the Secretary of the Navy and review by the President of the United States, is the largest and most important gathering in one place of the ships of the United States navy that has ever occurred. Last year ninety ships were mobilized at New York, whose total tonnage reached 878,684. To-day there are gathered in the Hudson River 128 ships of all classes whose aggregate displacement is 720,495 tons. That the ships of New York and visitors from the various states will have under their eyes, at one and the same time, probably the whole fighting force of the United States navy is shown by the fact that the latest official

summary of the displacement of all the ships of the United States navy gives the total as 720,495 tons. So that the fleet at New York is only about 86,000 tons short of including the whole of the effective navy."

It is very late to quote the above from your October 12th issue, but since Secretary of State Bryan has made his hurried trip to California, it seems to us that the above facts are a great deal truer to-day than then. When you say, "the fleet at New York is only about 86,000 tons short of including the whole of the effective navy," we wonder where that 86,000 tons is. Does it include that one battleship that might have swelled the number to thirty-two at the review? It certainly does not include the six armored cruisers that constitute the bulk of the fleet, or the famous fleet of one ironclad battleship on the entire Pacific Ocean, or the "Saragosa" (formerly the "New York"), the "Montevideo" or "Monadnock" of the Atlantic station. And let us add that the last two named vessels belong to the class that are used in gunnery experiments on the Atlantic side.

The thirty-one battleships that participated in the great review at New York carried a total of 122 12-inch and 13-inch guns. The total number of 13-inch guns on the Pacific is, for some time being, only 14. The "Oregon" carries eight 13-inch instead of the original four 12-inch and eight 8-inch. The monitor "Montevideo" mounts two 12-inch and two 10-inch guns, and the "Monadnock" four 10-inch guns. This is a total of eight 13-inch, two 12-inch and two 10-inch guns on the Pacific to-day, and each one of these ships is in reserve, and then, too, the guns are of old patterns and not to compare with those of the crack ships of the Atlantic fleet.

The effective fighting force on the Pacific consists of the armored cruisers of the "California" class of 11,080 tons displacement, which form the Pacific fleet, and the old armored cruiser "Saragosa," of 8,150 tons, of the Asiatic fleet. The remaining vessels of these two fleets are cruisers and gunboats that are fit only for police duty. The "California" class mounts four 8-inch and fourteen 6-inch guns, the "Saragosa" four 8-inch and two 6-inch, so it is easily seen that the heaviest gun in active service on the Pacific to-day is of 8-inch caliber, and only twenty-eight in number, compared to the total of 104 12-inch guns that are carried by the twenty ships of the Atlantic fleet.

As an argument for having a sufficient naval force on the Pacific, a comparison of the territory supposed to be guarded by the navy is interesting. On the Atlantic side there are 1,000 miles from Maine to Porto Rico and the Isthmus Canal, on the Pacific this line would stretch from Panama on the south to Tutuila, Samoa, thence to Guam and the Philippine Islands, and back again to the vicinity of the Hawaiian Islands, from where it would go straight on to Alaska. This experience gives one the unformed air of, of the vast amount of territory over which the two small fleets on the Pacific must hover as compared to that guarded by the Atlantic fleet.

Mt Vernon, Wash.

## Recent Assaults Upon the Patent System: What They Mean to Manufacturers

PENDING in Congress to-day is a bill which cuts down from nineteen years to three years the most essential protection now afforded manufacturing patent owners, and lays upon manufacturers of patented articles prohibitions and penalties in respect to the merchandising of patented articles which, if imposed upon the merchandising of articles generally, unpatented as well as patented, would never for a moment be tolerated in any commercial country in the world. This bill cannot be disregarded as pure pork legislation. Reported favorably by the House Committee on Patents in the last Congress, and reintroduced in the present Congress by Chairman Oldfield of that committee, its possibilities of evil to small manufacturers, to independent inventors, and to their industrial research, experimentation and development, that alone keep America in the front rank of nations, constitute the most menacing cloud upon the business horizon.

The Office that bill proposes that if any inventor shall establish in a Federal District Court that a patent owner, who has purchased a patented invention from the original inventor, is withholding it "with the result of preventing any other person from using the patented process" more than three years after the patent is issued, the Court shall order the patent owner to grant to the applicant a license to use the invention upon such terms of royalty as the Court "deems just."

The burden of litigation which this proposal in volume would give large corporations the greatest advantage in the case of every patent owner.

The excuse offered for this universal prescription of patents is that patents are sometimes "suppressed." Thomas A. Edison has time and again declared that he never knew of a valuable invention being suppressed for twenty years. The House Committee on Patents took testimony upon the Oldfield bill and

not a single case of suppression" was cited. Almost unanimously the witnesses emphatically opposed the bill with conclusive proofs that its proposals were unwise.

If the small independent manufacturer could be compelled to license his big competitors to manufacture all the second and third best inventions that he has acquired tested and laid aside in favor of his best invention, his big competitors, with their superior advantages of capital and selling organization, could soon crowd the smaller manufacturer, even with his superior invention, completely off the market.

Instead of preventing suppression of inventions, the Oldfield bill would really facilitate it.

The Oldfield bill proposes that whenever any patent has been used in connection with any combination in restraint of trade, the patent may be condemned and forfeited, and further that "such restraint shall be conclusively deemed to have been or to be unreasonable" and in violation of the Sherman law. If the validity of any patented article does any of a number of acts none in these acts are forbidden to manufacturers or dealers in patented articles. Only those who have spent their time and money advancing progress and the arts by developing and introducing new and useful inventions are subjected to this wholesale outlawry. But every manufacturer and dealer in patented articles becomes a criminal if he tries to secure a year's business as a condition of selling to a dealer. If he tries to hold the dealer back from selling to his retail customers, he is exclusively or to a certain extent. If he tries to hold the dealer to his agreement to maintain a standard price on the patented goods if he licenses the use of a delicate patented machine on condition that it be used only with specially adapted supplies or in connection with specially adapted machinery necessary to insure the perfect operation of the patented machine if he limits the licensee's use of the patented machine in a particular line of business so that he may license to others the adapting and introducing of new machines in other lines of business, if he agrees with a retailer in a town to sell his patented goods to no one else in the same town or to sell to other retailers only on less favorable terms, in consideration of which the retailer shall purchase his goods at a lower price than his patented goods in any particular territory at a less price than he sells elsewhere.

The penalty for doing any of these things is the forfeiture of the patent a fine of five thousand dollars and a year's imprisonment. It is a bill that would deprive designers and the cost of suit and attorney's fee to anyone who comes in within three years the reverter and proven any damage. But manufacturers and dealers in every other form of property are left absolutely free to do any or all of these things.

In the closing days of the last Congress, members of the House Patent Committee, representing both parties, united in a minority report against the Oldfield bill. They showed that every evil for which the bill had been urged could be cured upon existing laws, and that under the Sherman act interpreted by the Supreme Court in many recent decisions, the patent laws afford no protection to any form of restraint of trade. Thirty-five years ago an assault upon the patent system embodying proposals almost identical with those of the Oldfield bill, was defeated in the United States Senate.

If American manufacturers and inventors, whose existence is now threatened by the Oldfield bill, join hands with the opponents of the Oldfield bill in Congress, the patent system can again be saved. A history of the issue of the bill is given in the *Scientific American*, published before the National Association of Manufacturers' annual convention, Detroit, Mich., May 21st, 1913.

## The Current Supplement

IN this week's issue of our SUPPLEMENT, R. Darling describes some experiments with liquid globules and columns. Our readers will recall the very elegant experiments with very large spherical drops presented by the same author several weeks ago.—Prof. W. H. Bragg, in an article entitled "The X-ray Crystallography," gives an excellent survey of the remarkable achievements in the recent investigations of corpuscular and other radiations.—Sidney Low discusses the birth rate in its relation to military armaments.—The cork industry is described and illustrated in an article, "Evolution from the Standpoint of Physics," by A. J. Lotka gives an exposition of the physical significance of the principle of the survival of the fittest, or, as it is stated in physical terms, the principle of the persistence of stable forms.—A very valuable article comes from the pen of Prof. E. B. Howard, the well-known physicist, on electric power direct from coal. The problem appears to be well on the way toward solution.—Prof. J. P. Norton writes on that important subject "The Changing Cost of Living," and gives us an account of comparative measurements made in this country and abroad.

## A New Paraveral Airship

By Walter Leendahl

THE Illinois Airship Company has constructed, at its Butterfield "shipyard," a new paraveral airship for a foreign government. The new vessel is the aeroplanoid Paraveral airship, and consequently bears the provisional designation P. L. 17. It was built in the remarkably short period of two months.

The new airship, like its predecessors, is of the flexible type, but it exhibits many radical innovations which greatly alter its external appearance. The structure is slenderly built, and closely approximates to the form of a shark. It is girdled by numerous hoops, which distribute the weight of the car and form and also the envelope stiffens. The latter does not show the characteristic yellow color of Paraveral airships, as its failure to impregnated with aluminum, which gives the vessel a beautiful silvery appearance. There are two propellers, placed to the right and left of the car, and above it. Each propeller has four blades of elastic steel only 1/32 inch thick. The propellers are driven by two six-cylinder Maybach motors, which have an output power of 400 to 120 horsepower. The speed of the new vessel, 41½ miles per hour greatly surpasses that of any other paraveral airship and has heretofore been regarded as unobtainable by man and his machine. In other respects also, greatly increased efficiency has been obtained. The available ascensional force is about three tons, and fuel sufficient for a continuous flight of more than twenty hours can be carried. The official trial trip, in Koxen, Leipzig, Dessau, and Halle occupied six hours. The foreign officers present were exceedingly well satisfied with this performance, and accepted the vessel for their government.

## The Good Roads Movement

FOLLOWING the recent publication of the *Good Roads Year Book*, which presents the road situation in the United States to date, the American Highway Association has begun the issuance of a series of instructive papers presenting the most important phases of road improvement from the standpoint of both the layman and the engineer.

Among the first to be issued is a reprint of the address of Wm. W. Finley, president of the Southern Railway, at the recent American Road Congress on "Good Roads and the Cost of Living." Mr. Finley holds that the cost of living is largely an economic question and that efforts should be turned toward increasing the acre of farm land under cultivation and increasing the yield of farm products per acre. He points to the well known fact that prospective farm settlers are largely governed by railroad and public road facilities, and that when these are not adequate, farm operations are discouraged. Increasing farm products by getting more people on to the land and by bringing a large area under more intense cultivation is largely a matter of transportation," said Mr. Finley.

Concerning public roads as factors to railways, Mr. Finley says: "May it not be a fact that the transportation needs of many localities that seem to be waiting on railway construction would be met more satisfactorily and more comprehensively by a system of good roads connecting them with existing railways? The railway should be located with reference to main traffic channels. It can no more take the place of the wagon road for the collection and distribution of traffic in a rural community than the wagon road can replace it as a main highway of commerce. Considered as parts of a general transportation system, the railway and the wagon road equipment each other. I believe that this relation should be recognized in the formulation of plans for road improvement."

Among other papers to be issued will be those which deal with the construction and maintenance of all types of roads, the selection and testing of road materials, adjacent accounting systems for the expenditure and accounting of road funds, the use of convict labor in road improvement, instruction in highway engineering in schools and colleges, the beautification of roadsides. The American Highway Association is composed of upward of 2,000 of the leading men and women of the nation and is conducting a great campaign of good roads education and reform throughout the United States. Its president is Logan Waller Page, secretary is J. E. Pomeroy, former Chief of Road Maintenance in the Department of Agriculture, and former Chief Statistician for the Joint Congressional Com-

mittee on Federal Aid in the Construction of Post Roads. The headquarters of the association are in the Colorado Building at Washington.

## Stimulating Plants by Radium

VARIOUS methods of stimulating plants in a state of rest to resume growth have been successfully adopted, such as the ether treatment, the warm bath process, injections, etc. The brilliant plant physiologist, Prof. Hans Molisch, some of whose work has already been described in this journal, now announces his discovery that radium has a similar effect, causing twigs of various kinds to begin "budding" much earlier than is normally the case.

We find an abstract of his experiments in the *Naturwissenschaften/Wissenschaften*. Herr Molisch made use both of the radium emanation and of radium salts inclosed in glass tubes or spread on metal plates. The tubes held radiumbariumchloride. The metal plate gave off strong  $\alpha$ -rays, which were almost entirely absent from the glass tube because of the absorption. In the experiments with radium emanation, the rays from a flask filled with an aqueous solution of radium chloride passed into a cylindrical glass vessel which was the culture chamber. The twigs placed in this were exposed to a radium emanation ranging from 1.84 to 3.45 milligrams. Only the twigs of *Hydrangea velutina* were used in the former case, but various plants were exposed to the emanation. The terminal buds of the twigs, which were subjected to the influence of the radium preparations for one or two days in December

A new Paraveral airship.

or at the end of November, and then placed in ordinary light in a greenhouse, budded in a short time, while those not thus treated budded much later or not at all. When the radium was not continued long enough no effect was visible. When too long continued the effect was inhibiting, injurious, or even fatal. The time chosen for the experiment is also important. In September and October, when the state of rest is finally established, the radium has no effect. In January or later, when the rest-period is already past, there is either no difference observed or else the twigs subjected to the rays seem slightly retarded. This is similar to the effect of the ether and warm bath treatments. The emanation had a more marked effect than the radium salts. This is because it influenced the plants more uniformly and from all sides. Other plants favorably influenced by the emanation were *Liriodendron tulipifera*, *Acacia hippocastanum*, *Hephasia plantata*, and a some degree *Acer platanoides*.

The process is too costly for commercial use, but is of scientific importance in connection with recent investigations of the effect of narcotics on the chemical composition of resting parts of plants. On growing parts radium preparations of little strength have an entirely different effect, as Molisch hopes later to demonstrate.

A Number of Shock Absorber Patents.—Patents Nos. 1,068,410 to 1,068,414 have been issued to Walter H. Cook, of New Orleans, for shock absorbers which include spring radium preparations of little strength have an entirely different effect, as Molisch hopes later to demonstrate.

## The Brazilian Battleship "Rio de Janeiro"

By Oscar Parsons

THE Brazilian battleship, "Rio de Janeiro," which was launched at Messrs. Armstrong, Whitworth & Company's shipyard in Newcastle-upon-Tyne, represents the largest battleship afloat, displacing 32,000 tons nearly 32,000 tons, with dimensions of 600 feet (w. l.) by 96 feet by 26 feet.

As originally designed she was to have displaced 32,000 tons and carried an armament of twelve 14-inch guns, but constant upon a change of program the plans were altered, "considerations of every kind pointing to the inconvenience of acquiring such a vessel." Drastic alterations were, therefore, made in the specifications and the present design substituted.

The main armament of fourteen 15-inch guns is carried in seven twin turrets of 9-inch armor, all disposed along the center-line, four being on the forecastle deck and three on the upper deck. When the first details of the ship became public it was asserted that the four-ton guns would be disposed in two triple and four twin turrets, and it was quite possible that some such idea was at one time considered.

The triple turret originated in Germany, but has never been adopted there, and in Great Britain it has always been regarded with disfavor, on that account it is not likely that the British Admiralty will ever send its belated installation in the "Rio" had the Brazilian Naval Commission originally decided to mount the guns. The present arrangement allows for all the weapons to have bilateral training with a fore and aft fire of four guns. A secondary battery of twelve 6-inch guns are mounted along the upper deck and in the superstructures, and of these six have axial fire, fore and aft.

The upper deck guns have 6-inch protection, while the remainder are behind shields. In addition twelve 3-inch  $\alpha$  2 are distributed over the superstructure and have a good all round concentration of fire. Three 21 inch tubes constitute the torpedo equipment.

The ship's protection consists of 9-inch water-line, lower and main deck plates. Forward, the main deck belt is 4 inches and the other two 6 inches in thickness, while aft the water-line and lower decks have 4 inches to within some 20 feet of the stern. Forward there is a 12-inch conning tower, and aft a small armored observation tower, at the base of the mainmast.

An interesting feature of the ship is the provision of three-armed decks of 1 inch, 1½ inch and 2 inch from above downward.

With a designed horse-power of 45,000 generated by Parsons turbines, the speed is expected to exceed 22 knots. The coal supply is 1,500 to 3,000 tons, plus all fuel—an exceptional amount for South American ships.

The "Rio" was laid down in December, 1911, and is to be completed early next year. In appearance she suggests a huge "Neptune," and will be quite the most formidable-looking ship afloat with her seven big turrets, lofty superstructures and boat deck, huge oblong funnels, tripod masts and arsenal of secondary and tertiary guns.

## Cork Paper and Its Uses

ENORMOUS quantities of cork are used annually for making tips on cigarettes. For this purpose the cork is converted into very thin sheets which constitute what is known as cigarette paper. The sheets are exceedingly thin and come in the market 4¼ inches in width and 6, 7, 8, 9, and 10 inches in length. A package of about two hundred and fifty sheets is scarcely an inch thick. Practically all the cork paper that comes to this country is sourced from the New York Customs House and is valued at (including 10 per cent duty) at about \$300,000 annually. It is estimated that approximately one half million dollars worth of cork is converted into cork paper every year, and almost all of this is used for making tips on cigarettes.

The thin cork is passed on large sheets of paper, which are passed between rollers and automatically covered with paste, while girls with dextrous eyes on the cork and smooth it down as the paper passes along. After this the sheets are passed through the cutting machine, in which the sheets are cut into strips 1½ inches wide and wound on reels for use in the automatic cigarette machines. Each of these machines has a capacity of 20,000 sheets of cork paper a day. The total number of sheets used in the world is about 100,000,000, or about a quarter billion square feet. The cigarette industry consumes large quantities of cork paper, and it is estimated that the cost of the sheets used in the cigarette manufacturing is from 5 to 10 cents a sheet.

THE BRAZILIAN BATTLESHIP "RIO DE JANEIRO"

# The Heavens in June

Some Data on Schaumasse's Newly-discovered Comet

By Henry Norris Russell, Ph.D.

THE first comet to be discovered in 1913 was found at Malmesbury on May 17, on the morning of May 17. It was then in the eastern sky, in 20 hours 55 minutes E. A and 10 degrees north declination, between Vega and Delphinus. Its motion northward, and pretty rapid, and it was visible in a small telescope.

Numerous observations have been secured, and a preliminary orbit was very promptly computed by Klose and Nicholson at the University of California. This shows that the comet was discovered just before its perihelion passage, which took place on the 18th. Its orbit is inclined about 20½ degrees to the plane of the ecliptic, and its motion is retrograde, i. e., it is going around the Sun in the opposite direction from the Earth and the other planets. When nearest the Sun it was 13½ million miles from him, and it, therefore, never came inside the Earth's orbit.

As it is moving in the opposite direction to the Earth, its apparent motion in the sky will for some time be rapid, and as it is far north of the plane of the ecliptic it is especially high in the heavens, and so is easy to observe. The phenomena of the motion which is at present available extends only to May 24th when its computed position is 10 hours 11 minutes plus 30 degrees. A plot of the orbit shows that on May 17th it was about 75 million miles from the Earth and approaching it. It will be nearest us about June 1st at a distance of some 65 million miles, and then recede with increasing rapidity. From the rough indications regarding its brightness which are available it seems doubtful whether it will become visible to the naked eye, and certain that it will not become at all conspicuous. Exact predictions of its track in the sky during June must wait, however, on tables based upon a longer interval of observation but it can be stated that, unless the preliminary orbit should turn out to be seriously in error, the comet will move nearly along a line drawn from  $\beta$  Lyrae to  $\gamma$  Ursa Majoris (or perhaps a little south of this), being near the former star about May 27th, and reaching the vicinity of the latter somewhere about June 20th.

Though these indications are necessarily rough, they may be of aid to amateurs who wish to try to "sweep" for the comet.

It will probably not be until all the observations have been laboriously discussed, long after the comet has vanished into the distance that we will know whether it is moving in an ellipse of long period, or being on a single visit in a perfectly parabolic orbit, though in the latter supposable event that it should prove to have a short period, this fact may be found earlier.

## The Heavens.

Turning to our stellar map, we may find with its aid many objects of interest, though the observer has at his disposal a telescope or merely a field-glass. One of the first regions in the sky is now full in sight in the south—the great star-clouds in Sagittarius and Scorpions. Even to the naked eye is this a magnificent spectacle, and the brightening of the Milky Way, on a clear night, is surprising. With a field-glass many brighter patches of small area may be seen in the Milky Way, most of which are star clusters, though a few prove when examined with higher power to be true stellar nebulae. One cluster in the little above  $\gamma$  Scorpions is particularly fine, and some of its component stars may be seen with a field-glass. There is no finer region anywhere for telescopic sweeping, what over the size of one instrument.

In Scorpions itself we may note the wide double star  $\alpha$ , easily separated by an opera glass, and even by the naked eye when the air is clear enough to give a good view of an object so far south. With a small telescope the stars  $\beta$  and  $\gamma$  are seen to be beautiful and easy to make. About half way between  $\alpha$  and  $\beta$  is  $\delta$  Scorpions, a globular cluster of stars, faint and so close to one another that in a small instrument it looks like a small nebula.

Passing westward into Libra, we find the star  $\alpha$  to be a beautiful pair, resolved by a field-glass.  $\gamma$  Virgo and  $\beta$  Boötes are all fine and well-known telescopic pairs, the first separable with two inches

aperture, while the last demands three inches or more.

Passing to the north we find that a Canum Venaticorum is a fine pair of 20 seconds distance, while the Pole-star itself has a companion of the same magnitude, about 18 seconds away.

$\beta$  Cephei (distance 13.5 seconds) and  $\beta$  Cygni (32.5 seconds) are fine easy pairs, and so is 61 Cygni (32.5 seconds) one of our nearest stellar neighbors.

Finally, in Capricornus, low in the southeast, the star  $\alpha$  is a fine naked-eye double, and a companion to  $\beta$  is easily seen with a field-glass.

Many of the most conspicuous constellations now visible have been noticed in this survey. Among the others we find Corvus, the tail of Hydra, and part of Centaurus in the southwest. Hercules and Corona Borealis almost overhead. Ursa Major in the northwest. Draco high in the north. Cepheus and Cassiopeia low in the northeast. Lyra high in the east, with Aquila lower down and farther south, and the small but conspicuous group of Delphinus, with the

is a morning star in Taurus, visible only just before sunrise toward the end of the month.

Uranus is in Capricornus, rising about 10 P. M. on the 10th, but not observable until after midnight. Neptune is approaching conjunction, and is practically invisible in the evening twilight.

The Moon is new at 8 P. M. on the 4th, in her first quarter at noon on the 11th, full at 1 P. M. on the 18th, and in her last quarter at the same hour on the 26th. She is nearest us on the 10th, and farthest away on the 26th.

As she completes the circuit of her orbit she passes through conjunction with Venus on the 1st, Saturn and Mercury on the 4th, Neptune on the 7th, Jupiter on the 10th, Uranus on the 21st, Mars on the 26th, and Venus again on the 30th, none of the apparent approaches being close.

Mercury and Neptune are in conjunction on the 24th but they are too near the Sun for the latter to be seen.

At 8 A. M. on the 21st the Sun reaches his greatest northern declination—23 degrees 27 minutes 10 seconds—and, in the language of the almanacs, "summer commences."

Princeton University Observatory

## The Rarest Trees in the Country

IT is an interesting feature of the flora of the coast of Southern California and the adjacent islands that they contain several plants extremely localized. If the theory of gradual extirpation of some plant forms can be accepted, at least one plant can be named here, which will show conclusively that once widely distributed plants will often be reduced to a few individuals and finally become wholly extinct. The Monterey cypress ( *Cupressus macrocarpa*) is confined naturally within the county of Monterey, California, and the Torrey pine (*Pinus torreyana*) has its limits restricted still more being found only in a narrow belt a few miles long on the coast near the mouth of the Salado River just north of San Diego, and on the island of Santa Rosa, California, the least widely distributed plant tree in the United States.

While the total number of individuals of these two trees still aggregates hundreds of thousands, there is one plant which in habits the small Southern California coast islands and is probably the rarest plant in America. It is the western ironwood (*Lyonothamnus floribundus*) and is the only tree species of the mallee family of plants. It was not found and described until 1884 by William S. Lyon, Forester of the State of California. On these islands is the last stronghold in America of this very peculiar type, which as it exists only in small patches, once occupied a much larger space on the continent than it does at present.

The *Philippine Archipelago Review* of February, 1913, reports two other very rare trees in the Formosan forests. One of these is the albizia (*Albizia leucodermis*), of which there is only one small cluster known to exist on the island. A still more striking case is that of the *Cassipouira* of Mount Mandal. The number of individuals of this tree has been reduced to only five living species.

## The World's Production of Tea

ALTHOUGH it is difficult to give a close figure for the world's production of tea, this is said to be over 1,127,700 (long) tons. This is not exaggerated will be seen from the following data for production. India, 123,200 tons; Ceylon, 63,000 tons; Japan, 10,400 tons; Formosa, 11,000 tons (estimation); Siam, 20,000 tons; Annam, 1,400 tons. To this is to be added at least 30,000 tons of compressed tea in tablets, which is put directly on the market by Chinese firms. There must also be taken into account the tea produced in China and Japan and consumed on the spot, this being estimated to be 5 pounds or less per head, so that for 245,000,000 inhabitants this figure at 774,800 tons. For the reason China and Japan do not figure in the support list, it is estimated that the total consumption of tea for the year of the world is 300,000 tons.

NIGHT SKY JUNE AND JULY.

ancient but less prominent figure of Sagitta (the Arrow) on the left of this. Finally, high in the south, is the tangled mass of Ophiuchus, straddling to carry the great Serpent which it is his fate to hold.

## The Planets.

Mercury passes through inferior conjunction (behind the Sun) on the 1st, and is an evening star for the rest of the month. He can be best seen in his closing days, when he sets about 9 P. M., and can easily be seen in the twilight a little south of the region where the Sun has set. He is apparently about as bright as Procyon, and brighter than either Castor or Pollux, near which two stars he passes about the 23rd.

Venus is morning star, in Aries, rising about 3 15 A. M. She is still exceedingly bright, and can easily be seen in full daylight. The only difficulty is to know where to look for her. On the morning of June 1st she is about 4 degrees south of the Moon, and should be easily found with a field-glass, and even with the naked eye, if the weather is really clear.

Mars is also a morning star, and is not far from Venus, about 18 degrees farther west and higher in the morning sky. He is a far less conspicuous object, needing an opera glass or a hundredth as much light as Venus, but, even so, he looks like a pretty bright star of about the second magnitude.

Jupiter is in Sagittarius, approaching opposition, but rises late (about 9 P. M.) on account of his great southern declination, and, for the same reason, is not favorably placed for telescopic study.

Saturn, having just passed conjunction with the Sun,

### How to Measure Closely With Ordinary Calipers

By E. D. Chapman

THE sketch shows how to get an exact measurement with ordinary calipers. The writer had to machine up a piston for a hydraulic press, and it was to be made the exact size of the old one. No micrometer was to be had large enough to take that size, so in order to be sure that the size was the same, a test

Measuring closely with the calipers.

indicator was attached to one leg of a pair of outside calipers, as shown in the engraving. The calipers were then set to the size of the old piston, and by so doing the pointer on the indicator was set so it would point at any certain figure. The sketch shows the reading at 20. By the use of the calipers fixed in this way it was possible to make an exact duplicate of the old piston. Of course it is understood that calipers rigged up in this way can only be used in transferring sizes to be used as a test.

### A Toolholder for Grindstones

By William Grützinger

WHEN grinding tools by simply holding them with the hands against the stone, frequent changes of angle will cause much extra labor and result in a poor job. A simple device to hold tools at a constant angle while grinding can easily be made and attached to the grinding stone as follows. Refer on each side of the base of the grinding stone, a wooden arm as pic-

Toolholder for grindstones.

tured in the drawing. These arms should be slotted. A board a little larger than the ordinary plane iron is cut and bored with a  $\frac{1}{4}$  inch hole, running from edge to edge. The board is fastened to the grindstone with a hinge. A belt is put through the slots in the arms and the hole in the board. The belt may be tightened up to hold the board at any desired adjustment. The tool to be sharpened is placed on the board and held firmly. This arrangement will allow tools to be set at any cutting angle.

### Jig for Turning Up Rough-threaded Bolts

By Joe V. Romig

NEEDING a hundred finished bolts of  $\frac{1}{4}$  inch diameter and having nothing on hand except rough ones already threaded, the writer was forced to rig up a jig of his own design with which he could turn up the body of the bolt concentric with the thread and the underface of the head at right angles to the finished body. How the work was done is shown in the accompanying illustration. A nut was made from a piece

Jig for turning up rough-threaded bolts.

of octagonal steel  $1\frac{1}{2}$  inches thick and  $2\frac{1}{4}$  inches long. This was checked up and drilled and then tapped to receive the threaded end of a bolt. A  $\frac{3}{16}$  inch hole was then drilled through the end of the nut. The nut was now taken out of the lathe, rechecked and counter-bored at the outer end of the  $\frac{3}{16}$  inch hole to receive the lathe stock centers. This completed the jig. The bolt was then screwed into the jig and placed in the lathe, as indicated in the drawing, with the head of

the bolt held in the chuck, after which the body and head of the bolt were finished.

### Hint for Boring a Straight Hole

By Joseph Vaghi

TO bore a straight hole  $\frac{3}{16}$  of an inch in diameter, 1 lengthwise through a 12-inch maple round,  $\frac{1}{2}$  of an inch in diameter, is far from a simple task, so the writer was informed by a company manufacturing bits. But as a large number of rounds had to be bored in this manner, the writer was compelled to invent a practical method of doing the work. After a number of schemes had been tried, a successful solution to the problem was reached. A piece of tool steel  $\frac{3}{16}$  of an inch in diameter was tempered at one end and

Bit for boring a straight hole

ground off to about one half its thickness, for about two inches from one end, as shown in the drawing. The tool was ground to a chisel point as shown in the drawing, and in order to make it run more easily, a little was filed off back of the cut. Running this through a steel bush at the rate of 1,500 revolutions per minute, the rounds were quickly bored at the rate of seventy per hour. Twenty-five hundred rounds were bored without a single miss, whereas in previous attempts with the best single groove bit on the market 80 per cent of the rounds were wasted.

### Rig for a Two-handed Saw

By Fremont Leland

THIS accompanying drawing shows how a two-man saw may be rigged up to be operated by one person. The writer designed this arrangement for the purpose of sawing a large number of logs single handed, and he found the device very successful. The saw horse was placed beside a post on which a pulley was mount-

Rig for operating a two-man saw single-handed.

ed. Another pulley was secured on a second post, while between the two a pulley block was fastened to the ground. A rope tied to the free end of the saw passed over the pulleys on the posts and under the pulley block between them. The opposite end of the rope carried a small weight. With this arrangement the sawing of the logs was greatly facilitated.

### Device for Holding Screws When Filing Them Shorter

By I. B. Spittell

A VERY simple device for holding screws while filing them down is shown in the accompanying illustration. It consists of a piece of flat iron about an eighth of an inch thick and any  $\frac{1}{2}$  of an inch by  $\frac{1}{2}$  inches long. The piece is bent to a U form. In the bottom

Device for holding short screws in a vise.

of the U-shape holes are drilled to receive screws of different sizes. In the sides of the U-shaped piece, slots are cut to receive a wedge or key of steel. In use the screw is fitted into one of the holes in the

U-shaped piece with the head inside and is held firmly in position by driving the key in place. Then the device may readily be secured in a vise while the projecting end of the screw is filed down to the required dimensions.

### Two Drilling Kinks

By Fred Horner

HERE are two kinks that have proved very accessible to the writer and he hopes will prove equally accessible to the reader.

Using a Rubber Band as a Drill Stop—A simple form of stop for small drills which are used in the hand-bench or in a drilling machine which has no depth stop is a rubber band. This is slipped over the drill to the required distance, as shown in Fig. 1, and each time that it reaches the face of the work the drilling is stopped. This device works well enough for occasional use and the band is more easy to work with than a chalk mark on the drill.

Rubber-faced Drilling Pad for the Tool Block—Fig. 2 shows a handy form of drill Fig. 1.—lug pad to be fitted to the tail stock of a Drill stop bench lathe. It is of particular use when drilling small brass plates and other highly polished pieces which are liable to slip on the surface of a metal pad and become scratched. A disk of rubber is connected to the face and this makes a soft bedding for the work, preventing it from skidding or

Fig. 2.—A rubber faced drilling pad.

slipping. The rubber disk will be found better in this respect than wood. As an alternative a small block of wood may be faced with rubber and held with the fingers against any part of the drilling pad.

### Mending a Broken Steel Tape

By George W. Colles

EVERYBODY who owns a steel tape will sooner or later want it mended. The two pieces should be joined by a butt strap, which is riveted to both pieces by means of small eyelets made for the purpose. Instrument makers furnish special tools costing \$5 for punching and setting the eyelets, but few will care to invest \$5 to mend a \$1 tape. A half hour's work at the bench and a few scraps of sheet metal will make a tool which is as satisfactory for practical purposes as a purchased one.

Take two pieces of strap-iron (a in the accompanying sketch) about 2 inches long and  $\frac{1}{4}$  inch thick exact dimensions immaterial.  $\frac{1}{2}$  to  $\frac{3}{4}$  of an inch wide depending on the length of the desired overlap. Take a thin strip of sheet metal c of the same size and having the combined thickness of the tape and strap, or preferably a little less, place all together in the vise,

Mending a broken steel tape.

and with a No. 50 drill bore three holes b. Removing the pieces from the vise lay the tape across one end of the strap and screw along the edge so as to mark a strip having the same width as the tape, which strip is to be cut off. Now replace the three pieces in the original order, cut three short pieces of No. 70 or 80 Stub's steel rod, and hammer them into the holes b for dowels. Two other holes d are now drilled along the center line of the cut off strip of the piece c. Cut a short piece e off the drill rod and file it obliquely on one end for a punch, and the apparatus is complete. All you have to do is to insert the tape and butt-strap as shown, and punch through the holes d with a punch e. It is necessary to have the drill rod e slightly larger than the drill, so that it will fit snugly in the holes. When the holes are drilled, the spools are inverted and turned over with a center punch and hammer. If the strip c is sufficiently thin, the tape and strap may be gripped in a vise during the operation, but I have not found this necessary.

# Inventions New and Interesting

Simple Patent Law; Patent Office News; Notes on Trademarks

## Recent Activity in the Explosive Pump Art

**A**n extremely important patent, of interest to inventors and the scientific world in general, was granted not so long ago to W. H. Smyth of Berkeley, Cal. This patent covers the application for which had been pending in the Patent Office since 1900, and which is a pioneer in the art, disclosing an internal combustion pump for raising water.

The Smyth pump, as seen in the accompanying engravings, is a duplex one, both parts being alike. A combustion chamber 1, the lower end of which is merged into a nozzle 3, extends into a casing 4, which constitutes the suction pipe of the pump. The lower end of this casing is provided with a check valve 5 and a strainer 6, and the upper end is separated from an air chamber 8 by the check valve 7. As seen in Figs. 1 and 2, the discharge of the pump is through a pipe 20, which connects with each air chamber 8. Two pipes 9, having valves 10 to control the flow of air or water, connect the air chamber 8 with the casing 4 just below the valve 7. A water piston, operated by the explosive charge, is located in each chamber 1 and the two casings 4. Air is introduced into the air chamber 8, an independent piston 11, free to move in response to heat pressure, is provided in the pipe connecting the two casings 4. This piston is actuated by the power piston 10 in the motor cylinder 15, through the link 18, lever 17 and rock shaft 12 and link 16 connected by the yoke 42 to the rod 13, which passes through a stuffing box 14.

As seen in Fig. 4, the motive fluid for operating the motor 15 is introduced and exhausted to and from the cylinder by a four way valve 43 through pipes 45, 44 and 46. This valve is operated by the link 16, carrying the tappet 53, which actuates the levers by riding over the cam surface 52. These levers 51 operate in turn, by means of the spring-operated tappets 50, the sliding tappet lever 48, which oscillates the lever 47 of the valve 43.

The apparatus for introducing an explosive mixture is shown in detail in Figs. 1 and 3.

A fuel reactor 27 (see Fig. 1) is connected to a vaporizer 28, which communicates with the combustion chamber 1 by a pipe controlled by the pump valve 24 and pipes 23 leading to a four way valve 22. The sparking device, located in the chamber 20, consists of a rocking wiper

30 secured on the shaft 31, which is provided with an operating lever 32, and a flat spring 33 attached to an insulated rod 34. The wires 40 and 41 connect the sparking device with a battery not shown. The tappet arm 29 on the shaft 12 operates both the valve 10 and the wiper 30 by means of the slotted link 36 carrying the pins 37 and 38.

The valve 22, which controls the flow of gases to or from the combustion chamber, is also operated from the rock shaft 12 by the tappet 31, the latter having a cam surface 21\*, which operates one arm

of a loosely pivoted bell crank tappet lever 22\*. This arm of the tappet lever 22 engages with the slotted link 36\*, which is loosely connected to the handle 23\* on the stem of the valve 22. The other arm of the lever 22\* constitutes a tappet, which, by engaging the part 21\* of the tappet 31, operates the spring-actuated valve stem 20 of the check valve 24, so that the tappet 21\* serves the double function of reversing the valve 22 and keeping the valve 24 open. The operation is now evident.

Motion is imparted to the piston 11 by the motor 15, which causes the water pis-

ton to move in the chamber 1 and make room for the charge in this chamber. The valve 22 being properly disposed, the action of the piston 11 and the travel of the water piston cause successive inflow of explosive charges and scavenging of the spent gases.

If we assume the explosive charge to be in chamber 1, the water piston will extend nearly to the valve 7, separated from the air and pressure in the air chamber 8 by this valve and by whatever air has been permitted access through the valve 5.

At this point the valve 10 is opened by engagement of the tappet arm 29 with the link 36 and the compressed air, or water under pressure from the air chamber, consequently flows beneath the valve 7. Thus the water piston is forced back against the charge, compressing it to the pressure of the air chamber, which is, of course, that of the atmosphere. The charge is prevented from escaping by the closing of valve 24.

Ignition now takes place resulting from the engagement of the tappet pin 37 with the end of the slot in the link 36, thus rocking the wiper 30 past the spring 33 by the connection of the link 36 to the wiper arm 32. The slot in the link 36 permits the valve 10 to close the moment the wiper arm 32 passes out of engagement with the spring 33. The expansion of the gases in the chamber 1 causes the water piston to be driven with great energy and speed through nozzle 3.

The spaces vacated in the chamber 1 and casing 4 are filled instantly (practically simultaneously with the expansion) by air through valve 5\*. That portion of the air admitted with the spent gases in the casing 4 of the expansion chamber will be cut off and separated from that in the charged chamber 1 by the incoming water through valve 8. The portion of air and gas in the casing 4 is thus trapped beneath valve 7, ready to be driven into the air chamber at the next operation of the water piston. That portion of the spent gases and air in the chamber 1 will pass out as exhaust. The cycle of operation of the Smyth pump is shown in Fig. 5, and described as follows:

1.—Explosive charge being taken in the left hand chamber and discharging the spent gases from the other chamber, the piston 11 being midway of its stroke, traveling to the right.

2.—A fresh charge in the left hand chamber and the right hand chamber completely emptied by the water piston, the spent gases of the previous operation having been driven off by the valve.

Fig. 5.—The White pump for utilizing full static pressure in compressing the charge.

Fig. 7.—The Chance apparatus for operating internal combustion pumps and compressors.

Fig. 9.—Poore and Harvey device for generating its own gas by electrolysis of water.

Fig. 1 to 5.—Detail of the Smyth internal combustion pump for raising water.

Fig. 4.—The cycle of operation of the pump.

the chamber, compressed to less than half of its original bulk by the admission of air pressure between the water piston and the check valve 7.

4.—Exhaustion of charge due to explosion of the waste water into the air chamber, preceded by the volume of air from beneath the valve 7. The inrush of the water through the lower check valve 8 induced by the injector, gravity and atmospheric pressure is also shown.

5.—Left hand chamber almost filled with water.

6.—Condition similar to 5, but reversed as to direction of the flow of gases and the movement of the water piston.

7.—Charge in the right hand chamber. The left hand chamber is completely moved of spent gases from previous explosion.

8.—Explosive charge in the right hand chamber ready to be ignited, thus completing the cycle.

It has been the custom in explosive pumps having two combustion chambers to cause the charge in the right hand chamber by the continued travel of the liquid piston after the waste gases in the other chamber have dropped to low pressure. In pumps of this character the continued travel of the liquid piston is sufficient to draw in the new charge, the explosion of the waste gases is accomplished by the return stroke of the piston and must be completed before the return stroke can compress the charge in the other chamber.

The necessity for prolonging both the out stroke and the return stroke of the piston to permit the drawing in of the waste gases and the explosion of the waste gases, introduces elements of time by which the capacity and speed of operation of the pump are correspondingly reduced.

A recent patent granted to Messrs. H. M. Chance and T. M. Chance of Philadelphia, Pa., shows a method of operating such pumps whereby the rapidity of action is increased by decreasing the time necessary for each out stroke and return stroke.

The apparatus, as seen in Fig. 7, comprises two combustion chambers 1 and 2 provided with inlet valves 8 and 4 for the introduction of the combustible mixture and two exhaust valves 5 and 6 for the discharge of the waste gases.

A spring-actuated valve 7, which controls the communication between the two chambers 1 and 2, is operated by the rod 18 and piston 14 in the cylinder 10. This cylinder communicates with the liquid in the chambers 1 and 2 by the passage 17, and the connection 18 leads to a source of pressure slightly greater than that at which it is desired to exhaust the waste products of combustion. The usual connection is connected to the air chamber of the delivery pipe 10 and section pipe 12 with inlet valve 11. This section pipe 12 is connected with the source of supply 13.

It is assumed that the chamber 1 contains a compressed combustible charge which has just been ignited, the waste 7 being open, the liquid in the conduit 8 is given a high velocity.

When the pressure in the chamber 1 falls below the predetermined pressure at which it is desired to open the exhaust, the valve 5 is opened and the valve 7 closed by the piston 14, operated by a pressure slightly greater than that now existing in the chamber 1, the scavenging piston at atmospheric pressure. The liquid in the chamber 3 now falls by gravity; the inlet valve 4 opens; and a new combustible mixture enters the chamber 2. At the same time the liquid rises in the chamber 1, expelling the waste gases. The valve 7 then closes.

Upon commencing its return stroke the liquid in the conduit 8 opens the valve 7, forcing the liquid into the chamber 1 and closing the valve 5 by the piston 14. The pressure in the chamber 1 of the liquid in the conduit 8 now causes the liquid to rise in the chamber 2, compressing the charge in this chamber. The cycle is then repeated.

It will be seen that the new charge is compressed by the pressure of the

while the products of combustion are being discharged, obviating the necessity for prolonging both out stroke and return stroke, and in this manner increasing both the speed and the capacity of the pump.

In explosive pumps of this character to compress the combustible charge in the same chamber in which it is exploded. A recent patent granted to C. B. White of San Francisco, Cal., shows a pump in which the charge is first forced into a separate chamber and forced thence into the usual combustion chamber by the pressure of the liquid in the delivery pipe. By this means, it is claimed, the full static pressure is utilized in compressing the charge.

The White pump, as seen in Fig. 8, comprises a combustion chamber 2 connected to the supply pipe 4 having the usual inlet valve 5, and the liquid 8, which communicates with the delivery pipe 19 through the pipe 6, in which is placed a check valve 7. This delivery pipe 4 is connected to the gas chamber 9 by a liquid piston 10.

The gas supply pipe 10, having the check valve 11, communicates with the chamber 9, the latter being connected with the chamber 2 by the pipe 12 having a pressure valve 13.

The exhaust valve 14 comprises a cup 20 provided with a bored extension 21 and a diaphragm 22. This diaphragm 22 is provided with a valve 23 adapted to enter the space between the cup 20 and the extension 21, and the valve 23 is provided with contact 25 to bridge the terminals 27 and 28 to close the circuit of the spark plug 16. A pipe 18 connects the delivery pipe 19 with the cup 20.

Let it be assumed that the pump is filled with liquid and an explosive mixture, the contact 26 closes the ignition circuit through the terminals 27 and 28 and the charge is exploded. The liquid is forced into the chamber 9, the piston 10 moves upwardly in the pipe 10, the pressure on the diaphragm 22 is removed, and the contact 26 is moved downwardly, permitting the escape of the waste gases.

After the explosion is spent, the liquid in the pipe 10 closes the valve 7 and the liquid piston in the pipe 6 and the chamber 9 forces the explosive mixture into the chamber 2 and compresses the charge against the water, which has by this time risen in the chamber 2.

The cycle is then repeated.

In internal combustion pumps it has been necessary after each explosion to draw in a fresh charge of combustible mixture from an outside source. This has necessitated gas and air connections which are impracticable when such pumps are used in mines and in many other places.

To obviate this difficulty, Messrs. Moore and Harvey of London, Eng., have recently patented a device which generates its own air by the electrolysis of water. No pipe connections whatever except those for the supply and delivery of the water are thus needed.

In Fig. 9, the current for decomposing the water is supplied by the dynamo 1 to the contact 27, which makes a sliding contact with the chamber 6 of the body A of the pump formed by the electrolysis of the water are mingled with air introduced in the chamber 2 through the air valve 14, and are exploded by the spark plug 17.

The ignition circuit comprises a primary winding 7, having a battery 8 and switch 9, and a secondary winding 10. The first 8 is connected by the lever 11, which is pivoted at 12, operatively to close the firing circuit.

The apparatus is operated by closing the switch 9 and turning on the dynamo 1. The first 8, controlled by the lever 11, is in a lower position, and the contacts 12 are in contact with the chamber 6.

As the water rises, the float 6 moves the chamber 6 out of contact with the contact 12, and, rising still farther, causes the lever 11 to contact with the contact 13, thereby closing the primary circuit.

The force of the explosion expels the water up the delivery pipe 1 into the tank 4, and also draws a fresh supply of water through the suction pipe 3. The return movement of the water closes the check valve 2 and compresses the new charge of explosive mixture. The cycle is then repeated.

The pipe 1 is then forced a spray for prolonging the vapor caused by the explosion.

## Legal Notes

**Employer and Employee.**—The Court of Appeals of the District of Columbia in *Babington v. Shanta and Shanta v. Babington* has held that even if B was in the employment of S, such fact did not deprive B of his right to claim damages as an inventor, even where it appeared that S's communication to B went no further than to advise a means for a certain result, S suggesting no means by which the result could be accomplished.

**Interference.** *Examined.*—The Interference Division of the Patent Office was instituted in 1860, prior to which time interference proceedings were tried and decided in the first instance by the principal examiner in charge of the division in which the interference arose. In the 44 years of the existence of the division, there have been 15 examiners of interferences beginning with the first incumbent, J. M. Thatcher, appointed July 17th, 1860, to the present incumbent, H. Stauffer, appointed May 6th, 1910. The longest term of service as examiner of interferences was that of Judge Walter Johnson, now a principal clerk of the Office, who held the service extended from November 8th, 1861, to July, 1902, a period of nearly 40 years and more than four times as long as the term of any other official who has occupied the position of examiner of interferences. The salaries of the examiners of interferences are as follows: J. M. Thatcher, 1860, J. H. Adams, 1870, M. H. Hopkins, 1870, J. B. Phillips, 1874, J. Newland, 1875, H. B. Bates, 1876, J. W. Miller, 1877, J. W. Church, 1880, P. McCarthy, 1883, W. Johnson, 1886, C. F. Pitts, 1902, C. C. Billings, 1905, J. B. Macaulay, 1907, F. Bayard, 1907, H. E. Stauffer, 1910.

**Property Rights Overthrown.**—The Supreme Court of the United States has before it on appeal from the Court of Claims the case of *May R. Peabody et al. v. the United States*, in which may be determined a question of interest in aviation, although aviation is not presently involved. It appears that the claimants own a property whose principal value is ascertained to result from its use as a seashore resort. Within a short distance of the claimants' land, the United States Government erected a coast defense battery known as Battery Bohlen, and the guns of this battery were so placed that the most valuable field of fire in time of war was the claimants' land, and it is claimed several years were fired on three occasions prior to the institution of the litigation, the shot each time passing directly over the claimants' land. On behalf of the claimants it is urged that the space above their land was subjected to use by the Government for the firing of projectiles across it, making it impossible to operate the hotel or use the land as a seashore resort, or for any other purpose.

The decision in this case may or may not determine some question of aerial law of interest in aviation, but it is believed that it will be the first adjudication by the court in a suitable case that makes a person or later be entitled upon to determine the relative rights of birdmen and landowners.

Berlin and Paris have police regulations forbidding the use of flying machines above the city, but it is not known that such municipal regulation exists in this country, although aviators have instituted regulations controlling the height of flight above cities. The question of entry both of self and to those on the ground

## Notes for Inventors

**A Yielding Metallic Railway Tie.**—Lookout W. Abbott, Dallas, D. C., in a patent, No. 1,054,600, shows a metallic railway tie in which there is a main plate upon which are mounted yielding metallic chairs whose tops are spaced above the bottom plate so that the chairs will bow or yielding loops to receive the rails.

**Advertising Theatrical Curtain.**—Patent No. 1,045,637 to John C. Taylor of Baltimore, Md., presents a theatrical drop curtain on which is mounted a movable advertising sign actuated by a motor, and the raising and lowering of the curtain operated through suitable means to stop and start the motor so that the advertisement will only be caused to operate when the curtain is lowered.

**Cream from Butter Fat.**—Joseph Williams of Derby, Conn., assignor to Will. Machinery and Construction Company of the same place, has patented, No. 1,058,408, a process in which moisture is removed from butter and the concentrated stables which are formed is used only to produce cream, when it is treated with milk and the resulting mixture is homogenized to form cream.

**A Novel Flower Vase.**—It is desirable to provide for holding flowers so that they can be secured in sufficient number for a bouquet. Muelke of Kilmarnock, Germany, has secured patent No. 1,045,580 for a flower vase in which there are mounted upon a base plate a number of tubes open at their upper ends and connected from the bottom to the top so that the flower stalks may be inserted into the tubes and will be held at any suitable height by the corrugations.

**A Fountain Map for Sinks.**—Isabel L. Lewis of Syracuse, N. Y., has obtained a patent for a fountain map, a fountain in which a suitable hose delivers the water to the map head, which head has a suitable handle, and the hose is connected to couple with both the hot and cold water spouts of a sink, so that the water of the fountain may be supplied to the map.

**A Stand-on-and Shaving Brush.**—A novel form of shaving brush, having a hollow handle and a reservoir chamber at the end thereof opposite the brush head, as shown in patent to Frederick James Munro, of Hartford, Conn., shows the reservoir chamber being elongated in the direction of length of the brush and so shaped that when filled with water it will operate automatically to maintain the brush in an upright position.

**Make a Magazine Smoking Pipe.**—Patent No. 1,055,489 to Allen A. Karnes of Holliday, Mo., presents a pipe in which there is a magazine chamber adjacent to and in communication with the bowl, and a number of openings from the bottom of the magazine chamber and may be operated to discharge successively charges of tobacco into the pipe bowl.

**An Armored Plate of Nickel.**—The claim of a patent to H. C. Underhill, of New York, is for a plate for treasure, safes and the like, made of nickel. The patent is issued to Friedrich Karl August Niederpennseltz, near Aum, Germany. The inventor secured a patent for an attempt to protect the armor by means of aqueous-like burners, it being asserted that it is more difficult to burn nickel than to burn iron, and that the nickel by combustion is turned into protion of nickel, which is much less fusible than nickel.

**An Old Cow-milking Machine.**—An early cow-milker that had a suspicious appearance because of the well-known co-operation of a water pump with the national milk supply, was patented in 1879 by a Newark, N. J., woman, who connected the barrel of an ordinary suction pump by a pipe with a sack or case of milk, and then having at the top a connecting band to grip the udder, the milk terminating at its bottom in four tubes to receive the teats and conduct the milk to the connecting pipe and the pump barrel, the pump being connected in its lower portion of the pump from the spout of the pump when the pump handle was operated in the usual way.

## RECENTLY PATENTED INVENTIONS

These inventions are open to all patents. The notices are inserted by special arrangement with the inventors. Turns on application to the Advertising Department of the Scientific American.

## Pertaining to Apparel.

**SAFETY POCKET-J. W. FENWELL.** River City, N. H. In this patent the pocket of the trousers is given a new proof pocket specially adapted for trousers, and having means whereby to prevent the contents of the pocket from slipping out when the wearer is in a sitting or reclining position.

## Electrical Devices.

**ELECTRIC RING BOX-J. DEERY.** 430 54th St. Brooklyn, N. Y. Mr. Deery's invention relates to electric switch boxes having a particular idea being to produce a switch box having parts actuated electrically and also having connections whereby the box and its parts can be electrically operated parts can be connected up as a portion of a block alarm system.

**PRIMARY BATTERY II. E. LITTLE.** 102 Broadway Ave. Bronx, N. Y. N. Y. An object here is to provide a structure in which maximum voltage can be secured at any time without injury to the cell. Also to provide a cell in which the active agent is a gas adapted to be continuously supplied during the use of the cell.

## Of Interest to Farmers.

**YOKER J. LORANT and J. LORANT.** (also called No. 2, 184,848, (also). The purpose of this invention is to provide a device for animals such as oxen and the like to enable the animal to move readily carry a load attached to the yoke. For this purpose use is made of

YOKER FOR DRIFT HORSES

a main shaft adapted to turnably connect the shaft or tongue of a vehicle the main bearing body mounted to swing on the main stem auxiliary bearings on the main stem body and head horns mounted to swing on the auxiliary bearings.

**INCUBATOR-J. H. LEE.** 1115 Harvey St., Omaha, Neb. This invention provides for wholly or partially enclosing and admitting light to certain and various sections of the incubating chamber and provides means whereby the incubator can be adjusted to the light to equalize or vary at will the temperature throughout the incubating chamber.

## Of General Interest.

**PUMP BRACE ARM PUMPING T. HOLMES.** 330 E. 40th St., Brooklyn, N. Y. The invention relates to the coupling of the typical includes a car mounted to slide up and down guides fixed on the frame in the case of a building so that the inmate in case of fire can utilize the same to make their escape by a quick descent to the ground.

**WASHER REPAIRER-D. T. VANCE.** Plant tree, N. C. This invention relates to devices for straining washers made of rice or similar material. An object is to provide a device which will straddle the washer while in operation on the part of an operator. It provides means for separating the rice and broken portions of the washers from the strong washers.

**INTELL-C. M. BYRNE.** Wood, Cal. There is a serious difficulty in securing members together by bolts, so that they will remain under varying conditions. With this invention this difficulty is overcome for the wedge or end member formed at the end of the device serves to spread the device, and force it into the member at the sides of the hole.

**MILB CARE-J. W. FENWELL.** River City, N. H. This case has adjustable arms for positioning, holding and holding the contents thereof whereby the contents of the case will when in the case be held compactly and in proper position to this.

**HAINPINS RAILROAD-J. C. HARRISON.** and J. H. THOMAS, respectively of O'Connell and Archer streets, North Adelaide South Australia. This invention relates to the method of the attachment of the feet to the top of the saddle. The feet is detachably attached to the flap of the saddle by means of fasteners which can be released and secured as often as may be necessary for any purpose as for instance to enable rapidly to be effected.

**STOPPING AND STOPPING DEVICE FOR RAILROADS INLANDS AND MARINE RAILROADS.** A. M. JAVIER. Dumas de la Courbe, also at Pointe à Pitre, Guadeloupe, France. The purpose of this invention is to enable the stopping of the train to be readily done in the case of the train being obstructed by the cars, or to effect a greater distance between the cars without inconvenience, moreover, the de-

vices can be quickly withdrawn from the bottle before the latter becomes empty and put on another bottle without loss of time, which, in a cold or other drinking machine, allows of greatly reducing the number of the pouring devices.

**CRACKS FOR METAL CYLINDERS-L. WELSH.** 3155 Grays Ferry Road, Philadelphia Pa. By means of this invention a crack is provided having a maximum of strength with a greatly reduced weight. It has a form which permits of long continuous use, and continuous. If desired, a permanent attachment to the cylinder, since the latter may be charged and equipped without the removal of the cracks.

**NON REFILLABLE BOTTLE-J. S. BACH.** 1001 Den St. Brooklyn, N. Y. The purpose here is to provide arrangements to permit pouring the contents of the bottle on tilting the same and to prevent spilling with spurious pourings. To accomplish this use is made of a closure located within the neck of the bottle and having a self-closing valve a vast and a pouring stop, the last having a cracked joint connection with the neck of the bottle.

## Hardware and Tools.

**COMBINATION TOOL-C. A. NORBERT.** Box 300, Port Jervis, N. Y. This invention comprises a meter square having a pivoted blade with a projector attached to indicate the position of the blade a spirit level and scratch saw, a recess or notch in one edge to adapt

COMBINATION TOOL

the device for use as a center gage and a plurality of means carried by the pivoted blade for marking a mortise on lumber, by the use of a screw.

**RAYON BLADE SHARPENER-C. L. ALLEN.** 500 E. 33rd St. Manhattan N. Y. N. Y. The invention provides a blade sharpener which is simple and durable in construction, easily manipulated and arranged to permit convenient and quick sharpening of the ordinary razors of the blades of various shapes of safety razors.

**LOCK R. FOLK.** 2 E. 120th St. Manhattan, N. Y. N. Y. This invention refers more particularly to a lock which comprises any suitable key-controllable mechanism in which a bolt actuated member, casing, a bolt therein, means for operatively connecting the bolt and the actuating member, and means whereby the connecting means can be rendered inoperative to adapt the bolt for manual operation independently of the key-controllable mechanism.

**HIT AND HOLDING-J. W. JOHNSON.** 514 Third Ave. New York, N. Y. The object of the invention is to provide a bolt holder or brace check arranged to facilitate the exchange of different size bolts in the case of different sizes in position and to prevent pulling of the bolt out of the socket while the bit is in use.

## Heating and Lightings.

**IN ANCHORING GAS MANTLE-A. F. VICTOR.** Manhattan, W. Va. This invention is an improvement in incandescent mantles, and has for its object the provision of means in connection with a gas mantle for increasing the light, and for concentrating the rays beneath the source of light.

## Maneuvering and Holding.

**WINDOW SUPPORT AND HOLDER-J. W. FENWELL.** River City, New Mex. The purpose here is to provide a device adapted to hold the lower part of a window at any desired elevation and a further hold in its position a device which may be utilized as a lock for the lower sash to prevent it from being raised.

WINDOW SUPPORT AND HOLDER

**MANEUVERING AND HOLDING DEVICES FOR PHOTOGRAPHY.** E. C. JOHNSON, D. R. S. Sacramento, Cal. This invention relates to apparatus for photography on which removable lenses are provided, and a device which will insure the least possible delay and trouble in making the removals of the lenses. By the use of this device there is little or no excuse for not removing the lenses according to the highest demands.

**LOCK TIE LAMP.** LOCK TIE LAMP, Orange, N. J. A. WOLKSTADT and J. L. BEEBE, Orange, N. J. This invention provides a lamp with a lens the latter presents

City, Iowa. This invention relates more particularly to elevator design, and put on especially to the case of things comprising movable members in connection with a drum platform, the timbers being adapted to receive the

DRUM AND SAFETY LOCK.

wheels of a wagon, and to drop under the weight of the load.

**ROUND REPRODUCING MACHINE-C.** RAYON BLADE SHARPENER, New York, N. Y. Among the principal objects which the present invention has in view are to provide a machine adapted to be operated by records of different shapes, to provide an attachment whereby the usual disc-operated machine may be utilized

ROUND REPRODUCING MACHINE.

for sound reproduction of cylindrical records, and to provide a simple mechanism for operatively connecting said attachment to the disk machine.

**PRIME MOVER AND THEIR ACCESSORIES.** PUMP AND PRIME MOVER-C. F. NORMAN, 91 W. Neptune St. West Lynn, Mass. This invention has reference to machines capable of use as pumps and as prime movers, and relates more particularly to a device of

PUMP AND PRIME MOVER.

this class which comprises a casing having an inlet and an outlet, a rotor in the casing a movable abutment adapted to cooperate with the rotor, and an operative connection between the rotor and the abutment, and located at the outside of the casing.

**REBUILT WHEEL-J. LORANT.** ITS Mechanic St., Portland, Me. In the present invention the improvement relates to the wheels of vehicles and particularly to those of motor cars, and it is the design of the in-

REBUILT WHEEL.

ventor to improve in various particulars wheels of the present character indicated to the fact that efficiency in operation may be promoted as well as economy of manufacture and simplification of construction.

**VEHICLE WHEEL-A. SCOTT.** care of W. C. Vandewater, care of First National Bank Building, Cincinnati, O. This invention provides a wheel with a band the latter presents

in the periphery to which, when on a rim and normally disposed, the band being held by a screw adapted to rotate on the rim and the rim in turn with members which, at the will of the operator, may be moved out of the path

VEHICLE WHEEL.

of the plume, so that the rim may rotate relatively to the fixed rim where the plume are disposed at the lateral openings in the fixed rim to permit removal of the rim from the fixed rim by moving the rim laterally relatively to the fixed rim.

**WHEEL-A. J. WILSON.** West St. Garden, Mass. This invention relates to wheels and has for its object an inexpensive, compact wheel, easy in weight and compact in construction, which can be used on level ground, as well as on hills, which can be easily steered, and

PORTABLE WHEEL.

when necessary, transported by the rider. This is accomplished by providing a frame mounted on runners, one of which is elevated and a seat on the frame having a collapsible back rest, which has means for facilitating the transportation of the seat by the rider.

## Designs.

**DESIGN FOR CARPET OR RUG-J. L. FOLLOM.** care of G. R. Reine, 32 Madison Ave., New York, N. Y. In this ornamental design for carpet or rug, the border is composed of three bands, and the center of up and down and across double and curving lines that form irregular shaped spaces filled with cross-hatch

DESIGN FOR CARPET OR RUG-H. A. HOWE, care of G. R. Reine, 32 Madison Ave., New York, N. Y. In this ornamental design for carpet or rug, the border is composed of an outer, and a inner band, and a center band, and the center band is composed of three bands, and the center of up and down and across double and curving lines that form irregular shaped spaces filled with cross-hatch

DESIGN FOR CARPET OR RUG-J. G. FOLLOM, care of G. R. Reine, 32 Madison Ave., New York, N. Y. In this ornamental design for carpet or rug, the border is narrow and sparsely dotted. The interior depicts a diamond with a horse and owl, chicken, dog and small girl with a toy-horse.

**NOTE.**-Copies of any of these patents will be furnished by the Scientific American for sale at the rate of \$1.00 per copy, plus the cost of the patent, this of the invention, and date of this paper.

We wish to call attention to the fact that we are in a position to render competent service in every branch of patent or trademark work. Our staff is composed of mechanical, electrical and chemical experts, thoroughly trained to prepare and prosecute all patent applications, irrespective of the complex nature of the subject matter involved or of the specialized, technical, or scientific knowledge required therefor.

We also have associates throughout the world who stand in the power of patent and trademark applications filed in all countries known to the United States.

## The Motor-driven Commercial Vehicle

This department is devoted to the interests of present and prospective owners of motor trucks and delivery wagons. The Editor will endeavor to answer any questions relating to mechanical features, operation and management of commercial motor vehicles.

### Steel Bodies for Motor Trucks

By Morris A. Hall

AMONG the things that the motor truck has inherited from horse-drawn wagons is the wooden body. Such repeated experience has shown that this material does not last as it should under the changed circumstances, the heavier loads, the greater speeds, the longer work hours, enabled to make the body safe for greater stresses, and wear, under them goes to pieces rapidly. This situation has brought about a demand for metal bodies. The first of these, and many built since and being built today, are not an unqualified success. The reason for this lies in the fact that they are put together with bolts or rivets, which do not withstand the stresses imposed by truck work a great deal better than bolts or screws on the wooden form.

More recently, a process has been developed for producing steel bodies, which includes the use of various successful welding processes in combination with the highly developed pressed steel as a material. The latter is much lighter than ordinary rolled steel sheets of equal strength, while the welding processes unite the members as firmly as the component parts of each sheet. The result is a lighter, stronger, longer lived body of lower first cost when built in quantity, lowered maintenance cost due to lessened depreciation and less time lost resulting from lowered weight.

Truck manufacturers recently have agreed upon standard body and total weights for given load capacities, basing their figures upon wood bodies. Now, if steel be used a saving results which may be taken advantage of in one of two ways, the body may be kept the same and the lowered tire and other wear taken advantage of, or the load may be increased by the amount saved on the body weight. When 400 pounds can be saved on a 5-ton truck body the standard weight for which is not 1,400, this much may be added to the usual 15-ton load, amounting to a 5 per cent saving in body weight. The usual mileage guarantee is for 5,000 miles, this means the addition of 500.

It is said the wear of rubber tires varies as the square of the load, the speed remaining constant. On this basis, a 5 per cent saving in body weight would be about 10 per cent saving in tires. The usual mileage guarantee is for 5,000 miles, this means the addition of 500.

The exact life of the steel body is not known, but may be inferred in this manner. A Brooklyn builder following the wagon method of riveting and bolting steel plates and structural forms together, has many in use which have seen 14 years' hard service in New York city, hauling coal, than which nothing is more sure. They were used for some years ago now, and granting that welded pressed steel bodies are twice as good the latter should give over 30 years' service. The life of an ordinary wood body does not average much over 5 to 6 years, although there are exceptional cases in which they have lasted, through light work, twice as long.

An advantage in favor of wood at first was the matter of painting. It was extremely difficult to get paint to stick to steel sheets, the result being that they had to be painted often to prevent rusting and the quick destruction of the body in that manner. In the welded pressed steel forms mentioned the bodies are unmetalled, and the enamel is baked on, so that it is as hard as porcelain and cannot be chipped off even with a hammer.

The nature of the materials used in

the trade which employs the truck has a huge influence. Thus the brewery delivery service for instance, the kegs have iron chains or bands which run down to a very tight edge. Thus they have a cutting property. They are put in and taken off the wagon rapidly. As a result the rump, posts, rails and other parts of the body are quickly cut up, and soon require repainting. So great is the need for this that the largest brewers, such as Blatz, Ruppert, Blumstein, Central, Lion, and others in New York city, maintain a large and well appointed repair shop which does nothing but repair the bodies. With the motor truck, time spent in the repair shop is a double loss, so this question is of double importance.

The newer forms of steel body would eliminate all this, while the hollow shapes used in the body construction would give greater resistance to sudden blows. The

### An Automobile Field Kitchen

By Our Berlin Correspondent

ONE of the most interesting exhibits at the St. Petersburg Automobile Show, which opened on May 18th, is an automobile field kitchen. This is mounted on a vehicle of 2½ tons carrying capacity attached as trailer to an automobile tractor.

The front part of the vehicle, immediately behind the driver's seat, comprises to the right and left two large shelves, each of a capacity of 60 liters (16.88 gallons), above which there are a number of pigeon holes for preserves, bread, etc. The rear part of the vehicle is taken up by the field kitchen proper, which mainly comprises a double walled steam kettle of about 200 liters (52.5 gallons) capacity. The space between the double walls is filled with glycerine, which

taken in them to the men in the field. It has a normal pressure of steam of about 2,000 mm. The kitchen, by the way, is very economical in operation, only about 18 to 22 kilograms (8 to 10 pounds) of wood being required for preparing the food for 500 to 200 men, while any other fuel available in the field can be used as well.

This field kitchen can be mounted on an automobile truck instead of on a trailer, thus allowing the motor to be used at the same time for the operating of kneading and chopping machines, etc., which are readily stored on the vehicle. However, the field kitchen car would in this case not be available for other uses, whereas the automobile tractor is advantageously employed for carrying such provisions as cannot be placed on the trailer.

### Tar Bonded Roads in Cincinnati

CINCINNATI is the scene of a number of important successful road construction where the macadam has been rendered automobile-proof by the use of a refined tar binder. This was one reason why the American Road Builders' Convention was held there in 1913.

Madison Road, the sole eastern thoroughfare in the city, affords the oldest instance of tar bonding. It carries a traffic so heavy that a contractor who took a traffic record, reported that macadam could not be used at all.

In 1907 the north side of this road was resurfaced with tar bonded macadam to afford a comparison with native rock asphalt and plain macadam. Within a year the tar bonded section had no clearly demonstrated its superiority that the property owners petitioned for more of it, and in 1908 the remainder of the road was accordingly reconstructed with the tar. Since then the road has been uniformly in excellent condition and has cost nothing for maintenance except a little patching and a partial treatment with tar. Before the use of tar binder, this avenue had required resurfacing every six months.

Krie Avenue was bonded with tar in 1905 and required no attention until 1912, when several holes were repaired and the surface was given a renewal treatment with tar. Before the use of tar binder, this avenue had required resurfacing every six months.

Observatory Road, another important thoroughfare, had been impossible to maintain in even reasonably good condition previous to the use of a tar binder in 1900. Since then it has been in excellent condition and required no attention until it received a surface treatment in 1912.

Grandin Road, another heavy traffic street, had required resurfacing twice a year until 1907, when it was bonded with tar. After that one surface treatment with tar was enough to keep it in good shape.

The tendency of the tar bond was interestingly illustrated on Hillside Avenue in 1912. On a steep hillside section there was a landing which shifted the foundation of the road. The larried surface, however, instead of breaking, stratified and twisted very much as if it were a big sheet of rubber.

In 1911 Cincinnati abandoned the use of plain macadam on all main thoroughfares and substituted the tar bonded type of construction.

An Acetylene Storage Tank.—A patent has been issued to the Washington, D. C., firm of Chicago, for an improved acetylene storage tank, which is a cylindrical tank, the ends of which are hemispherical, and the interior of which is divided into a number of compartments by a series of transverse partitions.

An automobile field kitchen for the Russian army.

Rear of the trailer, showing the kitchen proper; also the motor tractor in which provisions are carried.

same is true of other firms, the coal body must withstand the water used in wetting the coal as well as the constant evaporation of the material sliding in or out. Metal alone will do this, consequently, if wood be used, the body must be steel lined. The same is true for mud and gravel, clinders, broken stones, brick or any similar material. For hospital use, especially in handling patients with contagious diseases, it is important that the body may be rapidly and readily cleaned out and fumigated. With wood this is an extremely difficult job. For tank or other liquid carrying bodies, wood has been abandoned, practically, steel taking its place.

And so it would be possible to go through the whole range of uses to which a motor vehicle might be put and prove that for each and every one the steel body has some advantage over wood, sufficiently weighty to warrant its use in preference to the latter.

on one hand protects the dishes against any risk of burning, and on the other hand allows the contents of the kettle, after getting out the fire, to go on cooking on the well known flames cooker principle. This is the more important as the smoke given out by the fire might draw the attention of the enemy to the troops encamped in the neighborhood.

The glycerine bath allows the contents of the kettle to be kept hot for about 6 to 8 hours. In addition to the main kettle there are arranged alongside a coffee ket of 20-gallon capacity with a special fireplace, reservoirs for carrying the apparatus used in preparing the dishes, sugar, coffee, and the like. The kitchen, given from both fireplaces are discharged through a common chimney.

This kitchen has been designed to prepare within 2½ hours food and coffee for about 200 to 250 men. As soon as the contents of the kettle are ready, it is transferred into the dishes (there are 10

# Dixon's Fake Graphite goes to the cause of Friction

It saves the bearing surfaces and prevents metallic contact.

## DIXON'S Automobile Lubricants

Dry graphite won't flow, so we combine it with the purest petroleum grease in several consistencies. Ask your dealer for Dixon's five for differentials and axles as well as the grease used by prominent drivers.

*Scientific American Supplement 1309*—The Gyroscope is a device which is used to determine the direction of the earth's axis. It is a very sensitive instrument and is used in many scientific experiments.

*Scientific American Supplement 1312*—The Gyroscope is a device which is used to determine the direction of the earth's axis. It is a very sensitive instrument and is used in many scientific experiments.

## Duamand's "Cold Light"

(Continued from page 495)

other words, an apparatus so small that it can be carried very easily in the hand. The absence, or rather the quick dissipation, of heat enables the operator to run the film off as slowly as he pleases and even to stop it entirely in order to study one particular picture on the screen.

Because of this rapid dissipation of heat, it is possible to employ celluloid in stead of glass plates for ordinary lantern slides. There is no danger of setting the celluloid on fire or of causing it to shrivel up. Duamand confidently prophesies that with his cold light it will be possible to use celluloid film  $\frac{1}{8}$  of an inch by 1 inch in size instead of glass plates  $\frac{3}{4}$  by 4 inches. The celluloid can be cut into long strips, perforated along the edges so that it can be printed mechanically, as in making moving picture positives. Indeed, Duamand claims that a single operator can make twenty five thousand celluloid prints a day. Those tiny photographs can be made by any amateur at a cost of not more than a cent, and can be projected on the screen by means of small, cheap projectors (Fig. 1).

Opaque bodies, postal cards, illustrations in books, and other objects can be directly thrown upon the screen in an instant of time by reflecting lanterns. The image, which appears in all its colors, relief, etc., on the canvas is  $\frac{3}{4}$  yards square. Two lanterns can be employed when dissolving views are to be projected, in which case it is not necessary to employ the usual shutters, but simply to rely wholly on the commutators of the apparatus (Fig. 2).

By means of cold light auto-chrome plates can be projected, which otherwise suffer when exposed to the electric arc. Powerful lights can be concentrated upon parts of the human body without danger of scorching them, with the result that foreign bodies can be located very readily in the muscles. The hand, when held close to the powerful cold light, appears transiently pink.

As one of our photographs shows, the cold light can be employed in photographing interiors. The inconvenience attending the use of ordinary magnesium flash powder are well known. Powerful cold lights render it possible to make very brief exposures without polluting the atmosphere of the small room with smoke.

With a small electric battery and a simple lens, a beam of light of long range can be cheaply produced. Such an apparatus will be found serviceable on small sailing boats as well as by soldiers. It is easy enough with such a device to telegraph optically for great distances.

## Disposal of New York's Sewage

(Continued from page 490)

tical experience. It is only the combination that is new. The water within a mile of the island in all directions varies from 7 to 40 feet in depth, the average being about 20 feet below mean low tide. The form of the island is shown in our front page illustration. It will cover about twenty acres. It is planned to build a rip-rap wall by laying large pieces of broken stone at the site upon the hard sandy bottom. As the water cuts away the sand from under the stone, more stone will be added until settlement ceases. Within the wall sand will be poured from a suction dredge. As the water is shallow, no serious difficulties will be encountered in the filling operations. The island will about 18 feet above mean low water, 1,000 feet wide and 1,200 feet long. It is estimated that the island may be constructed for about \$615,000. At the landward end of the island there will be a small harbor for the tank steamers that are to carry the sludge out to sea. A shelter will be provided by a breakwater.

The tunnel under the bay will be 34 feet in diameter. Starting with the siphon under the East River, it will be 8 feet 6 inches in diameter and will be blasted out of solid rock at a depth of 110 feet. After passing under the river it will rise to a level of about 20 feet and have with

## AMERICA'S GREAT DEPARTMENT STORES RELY ON WHITE TRUCKS

GIMBEL BROTHERS, New York City, operate  
Forty-Two White Trucks

Nowhere is the superiority of White Trucks better illustrated than in Department Store service. With the great commercial houses, efficient and reliable deliveries are one of the most important items of the business. Cost of delivery is also a paramount consideration. It is on account of dependability and economy that practically every one of the prominent stores of America are standardizing their delivery equipment with White Trucks.

407 White Trucks are operated by 95 Department and Dry Goods Stores at the present time, and the number is increasing daily.

There are 3500 White Trucks now in Service.

## THE WHITE TRUCK COMPANY CLEVELAND

Manufacturers of Gasoline Motor Cars, Trucks and Taxis

## G. V. Electric Trucks

Over 3000 G. V. Electric Trucks and Wagons are now in daily service, many of them from six to eleven years old.

The General Vehicle Company, Inc., has been the pioneer of the world in developing and standardizing Electric commercial vehicles. Its growth has been slow and sure. Production facilities will be tripled this year, because the G. V. reputation for building a high grade product and selling it as road transportation machinery should be sold, has made this expansion necessary.

Before you motorize—yes, before you buy even your first truck—you owe it to your business to thoroughly investigate our product and our standing.

Six capacities. 750 pounds to 5 tons.

## Valuable Books

### The Modern Gasoline Automobile

BY C. D. DAVISON. 16mo., 196 pages, 140 illus. \$1.00. This book is a complete and up-to-date guide to the modern gasoline automobile. It covers the latest developments in engine, chassis, and body construction, and includes a detailed description of the various parts and their functions. The author is a well-known expert on the subject, and his book is highly recommended for anyone interested in the modern automobile.

### Scientific American Reference Book

EDITED BY H. S. HOPKINS. 12mo., 154 pages, 126 illus. \$1.00. This book is a comprehensive reference work on the latest scientific discoveries and inventions. It covers a wide range of subjects, including physics, chemistry, biology, and geology. The book is written in a clear and concise style, and is highly recommended for anyone interested in the latest scientific news.

### Wireless Telegraphy and Telephony Simply Explained

BY H. S. HOPKINS. 12mo., 154 pages, 126 illus. \$1.00. This book is a comprehensive guide to the principles and practice of wireless telegraphy and telephony. It covers the latest developments in the field, and includes a detailed description of the various parts and their functions. The author is a well-known expert on the subject, and his book is highly recommended for anyone interested in the latest scientific news.

### The Scientific American Handbook of Travel

BY H. S. HOPKINS. 12mo., 154 pages, 126 illus. \$1.00. This book is a comprehensive guide to the latest scientific discoveries and inventions. It covers a wide range of subjects, including physics, chemistry, biology, and geology. The book is written in a clear and concise style, and is highly recommended for anyone interested in the latest scientific news.

### The Scientific American Cyclopedia of Formulas

EDITED BY H. S. HOPKINS. 12mo., 154 pages, 126 illus. \$1.00. This book is a comprehensive reference work on the latest scientific discoveries and inventions. It covers a wide range of subjects, including physics, chemistry, biology, and geology. The book is written in a clear and concise style, and is highly recommended for anyone interested in the latest scientific news.

### Concrete Pottery and Garden Furniture

BY C. D. DAVISON. 16mo., 196 pages, 140 illus. \$1.00. This book is a comprehensive guide to the principles and practice of concrete pottery and garden furniture. It covers the latest developments in the field, and includes a detailed description of the various parts and their functions. The author is a well-known expert on the subject, and his book is highly recommended for anyone interested in the latest scientific news.

Published by THE SCIENTIFIC AMERICAN BOOK CO., Inc., Publishers, New York City.

"Don." He really never makes the sound of b, d, k, l or r. When he utters a word expressed by *ch* unique, not much effort is required from a susceptible hearer to receive the sound as "Hunger." When in making phonograph records the questioner asks merely "Was?" the dog gave the customary answer, "Don," "Hunger," "Haben, haben," "Auchen," etc., of which however only two out of sixteen answers were intelligible. Of one hundred and sixty-eight answers preserved on phonograph records, seventy-one per cent were displeasing, and of the moonable noises a sixty-eight per cent were given when a considerable pause had elapsed between the last answer and the question. The "answers" were really incorrect fully as often as otherwise. Dumbstruck hearers could seldom distinguish his "Hunger" from his "Haben," or his "Ruhe" from his "Kuchen," etc. It was as easy for others to perceive some of these same sounds as "Explosion" or "Hallelujah," "Hush" or "Hong." Here it seemed to the author we have a case quite parallel with our common interpretation of the night-eagle's calls as "ship-poo-Will," when in fact the sounds are nearly "Pif-fah-rith," and with the common German interpretation of their *Sinaken's* "kuevit" or "kuevit" as "komme-und," thus making him in popular superstition the messenger of death. But for a strong and unblinded tendency thus to "appreciate" them, neither these calls nor the words of Don would be taken as other than meaningless noises.

On psychological grounds, Mr Pfingst concludes, the explanation is comparatively simple: the untrained do not make the effort to discriminate between what is actually given in perception and what is merely associated imagery, which otherwise gives to the perception a meaning intelligently unimportant and they habitually ignore the important part which suggestion always plays in ordinary situations.

These explanatory truths being accepted we may expect the majority of animal lovers to continue to read their own mental processes into the behavior of their pets. Nor need we be astonished if even scientists of a certain class continue at intervals to proclaim that they have completely demonstrated the presence in lower animals of "intelligent imitation" and of other extremely complicated mental processes— inferred from the results of brief and honestly superficial tests, and published as proven facts without further reflection.

### Naphthalin as a Binder for Anthracite Briquettes

THE pitch commonly used as a binder in making briquettes of anthracite is rather dear, hence a cheaper substitute has long been sought. Naphthalin, an ether by product of the coke-ovens, is especially fitted for this purpose, and many experiments have been made with the object of evaporating it and mixing it intimately with the particles of coal by means of superheated steam.

The process proposed by Busch-Foehr has hitherto not been very successful, but recently, according to Gilschew, it has been considerably improved by Schürer and made practically useful.

The naphthalin is melted in a melting pot by steam at about 300 deg. Cent., and then led into the coil of an evaporator in precisely measured quantities. The coil is played upon by superheated steam at 300 to 350 deg. Cent., so that the naphthalin fits to the coil evaporates.

The steam issuing from the evaporator drives an apparatus which sucks the evaporated naphthalin out of the coil and forces it into the steam heating apparatus filled with coal, where the two are thoroughly mixed.

Actual experiments prove that by using a percentage of naphthalin in place of the pitch a saving of 0.8 M. per ton is effected.

In this connection it may be mentioned that naphthalin is also finding an application as fuel for combustion motors. According to La Neufve, at the Crescent works a 70 horse-power naphthalin engine is being built for use on the Siberian Railway.

## United States Standard Motor Truck Tires

and this advertisement tells why

You can get everything in a United States Tire that you can get in any other tire besides many things that you will find in no other tire

United States Tires are by far the most easily manipulated tires on the market. Fifteen minutes is all the time required to make a tire change. And your own driver can do the job.

United States Tires are guaranteed for ten thousand miles of service (conditional upon this mileage being used within one year)—an unprecedented guarantee up to the time that United States Tires were placed on the market.

United States Tires are backed up by the most efficient tire service department in the country.

Our completely equipped service stations in practically every large city protect your trucks day and night against being laid up on account of tire trouble.

Can you name a tire that compares with United States Tires at any of the above points?

Then why not use them as exclusive equipment?

## United States Tire Company

## Warner AUTO-METER

MAGNETIC PRINCIPLE

Model D-2  
Price \$145

### By Eliminating Wear We Eliminate Error

**A**LL METAL-TO-METAL contact, with its friction and wear, is entirely eliminated from the speed indicating mechanism of the Warner Magnetic Auto-Meter. With the elimination of wear, goes every possibility of error in speed, mileage indication, and record, for metal-to-metal friction—which means wear—and error are synonymous. The latter begins exactly where the former does. It is impossible to have wear without error.

The magnetic Warner registers its speed on an aluminum disc as the result of the invisible, but direct and positive, drag of a tungsten steel magnet.

There can be no wear to cause inaccuracy, because in the Warner there is no physical or metal-to-metal contact—just the positive, accurate drag of the magnetic torque.

Centrifugal speedometers register speed through the linkage of delicate metal pins, coil springs, heavy threatening weights and small, rapidly wearing brass parts.

Centrifugal instruments make 25-30 revolutions per mile. At this excessive velocity the complicated centrifugal speedometer cannot possibly retain its accuracy.

The Warner magnetic type speedometer revolves only one-fourth as fast as the centrifugal; therefore it must be four times as efficient and reliable.

Insist that your car be equipped with a Warner Auto-Meter. Write us for illustrated and interesting literature on speed and its registration.

The Warner Auto-Meter Factory, Dept. 11, Beloit, Wisconsin

## SCIENTIFIC AMERICAN HANDBOOK OF TRAVEL

*With Hints for the Ocean Voyage for European  
Tours and a Practical Guide to London and Paris*

By ALBERT A. HOPKINS, Editor of Scientific American Reference Book

**Q** At last the ideal guide, the result of twenty years of study and travel, is completed. It is endorsed by every steamship and railroad company in Europe. To those who are not planning a trip it is equally informing. Send for illustrated circular containing one hundred questions out of 2,500 this book will answer. It is mailed free and will give some kind of an idea of the contents of this unique book, which should be in the hands of all readers of the Scientific American. It tells you exactly what you wish to know about a trip abroad and the ocean voyages.

### WHAT THIS BOOK CONTAINS

500 Illustrations	The Sea and Its Navigation
8 Color Plates	Statistical Information
8 Maps in pocket	Automobileing in Europe
All About Ships	400 Tours, with prices
"A Letter-Box"	Practical Guide to London
Green Records	Practical Guide to Paris
Names 2,000 Hotels, with prices	

500 PAGES 500 ILLUSTRATIONS

## Down where Nature cannot send her cooling breeze Science sends the Electric Fan

Down in the caverns of steel and stone where armies of office workers are meeting the strenuous problems of a business day—where excessive heat tends to retard the productive power of human energy—there electrical science carries the refreshing help Nature finds it so difficult to give.

The G-E FULCRIC FAN, the result of twenty years' experience in the great factories and laboratories of the General Electric Company, is one of Electricity's most effective means of increasing man power by increasing man comfort—of raising the standard marked by that magic word Efficiency.

In the home as in the office and factory the G-E Electric Fan is efficiency's first aid—summer comfort's best assurance.

And it gives both with a truly modern economy. It can be operated four hours for a cent—is readily attached to any lamp socket—gives a lifetime of satisfactory service.

The EDISON MAZDA LAMP is another proof of electricity's great service to efficiency and to comfort. This wonderful lamp has scratched electricity from the luxury list by giving more light for less money. In fact, it uses but one-third the current required by the old-style carbon lamps.

With the current you save by using Edison Mazdas, you can run your G-E FAN or any of the many G-E devices for increasing the comfort of the home. With the G-E ELECTRIC FLATIRON, for example, you can do the family ironing, indoors or out, in less time, with less labor, and less physical discomfort than ever was possible with the old-fashioned stove heated irons.

Any electrical dealer or lighting company will gladly show you the various styles and sizes of G-E Fans, Flatirons and Edison Mazda lamps.

BLOWING A HEAT IN A BESSEMER CONVERTER.—[See page 514.]

## Engineering

**Completing the Colapere Cut.**—Two steam shovels working from opposite ends of the Colapere cut at grade stop on the afternoon of May 26. This, of course, does not mean that the excavation is finished, but merely that it has been carried down to grade. Considerable work must still be done to extend the canal to the required width.

**Our Dangerous Streets.**—During the year 1911, 352 persons were killed by automobiles in the streets of Greater New York. This is a record. The percentage taken from daily newspapers show 13,042 persons hurt by automobiles, 704 by street cars and 317 by wagons. In London, which in 1911 had a population of over 7,000,000, 410 persons were killed by vehicles, while in Paris, with a population of over 2,000,000, there were 226 deaths and 18,179 injuries in all classes of conveyances.

**The Moffat Tunnel Through the Continental Divide.**—At a recent election in Denver, Col. the Moffat Tunnel Amendment was carried by a large majority. This provides for a Tunnel Commission which will arrange for the construction of a six-mile tunnel through the Continental Divide for the Denver and Salt Lake Railroad. The eastern portal of the tunnel will be at Tolland, 35 miles from Denver. The tunnel will be 6 1/2 miles in length and its cost is estimated at \$1,000,000 and four or five million dollars. It will reduce the route from Denver to Salt Lake City to 66 miles as against 187 miles by the Denver and Rio Grande route, which is at present the shortest. The tunnel will be open to all western railroads entering Denver. Eventually it will be bought over by the Denver and Salt Lake Railroad, but the city will retain perpetual rights to carry water power through it. Work will be commenced at once and it is hoped that the tunnel and the Denver-Salt Lake Railroad will be completed in 1915.

**International Engineering Congress, 1915.**—In connection with the Panama-Pacific International Exposition, which will be held in San Francisco in 1915, there will be an International Engineering Congress, in which engineers throughout the world will be invited to participate. The congress will be organized under the auspices of the following five National Engineering Societies: American Society of Civil Engineers, American Institute of Mining Engineers, the American Society of Mechanical Engineers, American Institute of Electrical Engineers, and the American Society of Architects and Marine Engineers. These societies, acting in co-operation, have appointed a permanent Committee of Management, consisting of the presidents and secretaries of each of these societies, and eighteen members resident in San Francisco. The exact character of the congress has not as yet been definitely determined, but it is hoped to make it widely representative of the best engineering practice throughout the world, and it is intended that the papers, discussions and proceedings shall constitute an adequate review of the progress made during the past decade and an authoritative presentation of the latest developments and most approved practices in the various branches of engineering work. The papers, which will be collected and published by the congress, should form an invaluable engineering library, and it is intended that this publication shall be in such form and at such cost as to become available to the greatest possible number.

**Aluminum and Magnesium Alloy.**—In a paper read before the Society of Automobile Engineers, Mr. Morris Medal gives some interesting data on the aluminum and magnesium alloy known as "magnalium," and describes the successful use of this alloy for the cylinders and pistons of gasoline engines, particularly where weight is an important factor, as in airplane work. The specific gravity of this alloy is 2.5, as against 2.66 of aluminum 2.66, and of aluminum alloy No. 12.82, while cast iron has a specific gravity of 7.5. Cast iron pistons show a tensile strength of between eighteen thousand and twenty thousand pounds per square inch, while magnalium shows a tensile strength of twenty-three thousand pounds per square inch. It is also very tough, whereas cast iron is rather brittle. Magnalium is an excellent bearing metal, allowing at 280 revolutions per minute and 360 pounds per square inch a coefficient of friction of 0.0056 as against 0.0075 of babbit and 0.0093 of phosphor bronze. With a pressure of 400 pounds per square inch, and the same speed, the coefficient of friction of bronze is 0.0086 as against 0.0066 of magnalium. One of the advantages of magnalium pistons is the absence of any tendency to vibration. The melting point of magnalium is 1256 deg. Fahr. at atmospheric pressure, which is less than the temperature often attained in the cylinder. But the magnalium pistons do not get as hot as iron pistons for the reason that the heat is conducted away more readily in fourteen times as great a mass of iron. An engine with magnalium pistons is less liable to pre-ignition than one with iron pistons.

## Science

**Searchlights for Airships** are being tested in Germany. A dispatch from Berlin states that a naval airship which is to take part in the spring maneuvers will be fitted with a 4,000-candle-power searchlight capable of illuminating the surface of the sea from a height of 5,000 feet.

**Dissociation of Calcium Carbide.**—The increasing use of electric arcs gives importance to all factors influencing its action under varying circumstances. At Brice-Kurzer at a recent session of the Académie des Sciences (Paris) proved that this compound was dissociated into its elements at a temperature of 900 to 1,000 deg. Cent.

**Supplement to the Public Health Reports** is the title of a new series of reports on topics of importance to health and disease, issued by the Public Health Service. Supplement No. 1, by Assistant Surgeon-General Rankin, deals with measles, which is described as a disease of much more serious import than is generally supposed.

An interesting **Subterranean River** in the island of Palawan of the Philippines has been explored and surveyed by two officers of the U. S. Coast and Geodetic Survey, and is described in the last annual report of that service. The river is navigable for a small boat for about 2 1/2 miles from its mouth, the tunnel through which it passes winding in places into large chambers containing beautiful stalactites.

**The Actinometer.**—A useful invention in the field of technology is the actinometer, a description of which was presented to the Académie des Sciences recently by M. Dumas. This little instrument is constructed with the exact measurement of the ultra-violet rays of luminous bodies. By reason of the increased application of these rays, particularly for purposes of sterilization of water, etc., it is probable that this may prove to be of much practical value.

**Natural Toothbrushes** are described in a consular report from Santo Domingo. It appears that the stems of several shrubs and trees are used by the natives in lieu of toothbrushes, and are known as "chew sticks." Among them are the stems of the orange, the lemon, and the membrillo or quince tree, all of which have an agreeable odor. The most commonly used is that of a plant known as "guano," probably the same as the one called in Spanish "palma de guano." The natives use the green stem, the end of which they chew up and use as a toothbrush. Various other sticks are similarly used elsewhere in the West Indies.

**International Rubber Congress.**—Preparations are being made for the International India Rubber Congress, which is to be held at Batavia, island of Java, in September of next year. A commission appointed for the purpose is now engaged in the preliminary work and is receiving the papers upon subjects connected with the rubber industry which eminent specialists are sending in. The work of the congress is divided into eight sections: 1. Botanical and zoological questions. 2. Climate and soil. 3. Culture and gathering of products. 4. Preparation and processes. 5. Methods of working plants. 6. Artificial rubber. 7. Commerce. 8. Publications. Dr. C. J. van Hall is secretary of the congress, and the headquarters are at Buitenzorg, Java.

**Death of Prof. William Hallack.**—The recent death of Prof. William Hallack deprives Columbia University of its senior Professor of Physics. Prof. Hallack had an active scientific career. After graduating from Columbia University and the University of Wurzburg, he was physicist for the Geological Survey at Washington, where he also acted as Professor of Physics in the Georgetown College. From 1899 to 1899 he was Professor of Chemistry and Toxicology in the National College of Pharmacy. He also occupied for part of this time the chair of astro-physics at the Smithsonian Institution. He was connected with Columbia's Department of Physics from 1892 onward. Had he lived he would have been the official measurer of the yacht which will compete in September, 1914, for the "America's" Cup. At the time of his death he was the official measurer of the New York Yacht Club.

**The National Academy of Sciences** will celebrate the 50th anniversary of its foundation at a meeting to be held at the National Museum, in Washington, April 22nd to 24th, inclusive. The programme will include quadruple addresses by the president of the Academy, Mr. Benson, President Hallack, of Yale; Prof. Arthur Schuster, F.R.S.; Dr. Hale, director of the Royal Society Observatory; Prof. Theodor Boveri, of the University of Wurzburg, and Prof. J. C. Kapteyn, of the University of Groningen. All the addresses will be in English. The National Academy, which is the premier scientific organization of the United States, corresponds to the Royal Society in Great Britain, the Académie des Sciences in France, etc., was incorporated by act of Congress approved March 4th, 1863. Its principal function being, as defined in the act, to furnish advice to the government "upon any subject of science or art." The latest meeting was held April 22nd, 1903, in the chapel of the University of the City of New York. It now has a membership of 120, besides 45 foreign associates.

## Automobile

**The Small Boy and the Horn Button.**—There are few things that can be more annoying than the small boy whose eagle eye never fails to search out the button for the electric horn and whose finger unthinkingly presses it to the accompaniment of a raucous blast that startles pedestrians and irritates drivers. There is an easy remedy on the battery. In appreciation of the fact, one manufacturer of a high-priced car has hit upon the novel scheme of concealing the button beneath the leather of the upholstery. The owner knows where the button is, but no one else can find it in its presence, for the wires leading to it also are concealed.

**Motor Spirit from Living Plants.**—Because the supplies of both crude oil and coal are more or less limited and are impossible of regeneration, a British chemist rises to remark, quite logically, too, that the better way to solve the impending fuel problem is to obtain motor spirit from living plants. Potatoes, beets and allied vegetables, containing largely of starch, are capable of fermentation and yield alcohol. It would seem, therefore, remarked the chemist, that the soundest solution of the problem is to be sought along the line of the production of fuel from some living plant which assimilates carbon by photosynthesis thereby avoiding the exhaustion of the source of supply.

**Unusual Application of a Fan Brake.**—For use in the mountainous parts of Swiss lands, a car has been developed in which the twist bands are supplemented by a large fan apparatus placed beneath the axle to the elements. When descending heavy gradients the fan is placed in motion thus causing a large displacement of air and materially retarding the car while at the same time the draft serves to prevent overheating of the rear wheel brakes and of the differential mechanism. The fan is so arranged that it can be driven through any one of the four speeds obtainable with the gear and the blades are adjustable to provide greater or less retardation according to the steepness of the grades negotiated.

**A New Road Material.**—A new road material designed to stand hard usage from automobiles is being tried by a Swiss engineer, W. Erlich, and is said to consist of a mixture of broken stone about the size of a hazelnut, but not limestone, with a binding material whose composition is not divulged by the inventor. The present project of the stone is heated at first from 100 to 150 deg. Cent. and mixed at this temperature with the melted composition. When in use, the mass is rolled in order to put it on the road. A road roller heated to a rather high point is passed over the surface, the rollers rolling back and forth six times. It is stated that very good road surface can be obtained in this way.

**Influence of Engine Strains on Design.**—It is interesting to note that the widespread adoption of engineering apparatus operating through gearing or belts, the perpetuity of the flywheel has resulted from the production of better flywheels. The gear used on cast iron flywheels scarcely can be expected to wear for any length of time and hence steel has come into more general use for the purpose. The attention can be expected to raise the already high factor of safety for the turning of flywheels is a rare occurrence it is a matter of comparatively common knowledge that the rim speed of the ordinary touring car flywheel frequently exceeds the safe limit and that rapidity of the occurrence is very common.

**The Cyclopedia in America.**—It is doubtful if that bird vehicle which abroad is called "cyclo" for the want of a better name, ever will prove popular in America. In the first place, the American tendency is toward greater carrying capacity, whereas the "cyclo" accommodates only two passengers. In the second place, the production of cars, American roads are not suitable for the little vehicle. Foreign roads, as nearly everyone knows, are, in the majority of cases, veritable boulevards; there are no ruts. Outside of the big cities in America, however, are surrounded by mud are the ruts rather than the exception. And as the "cyclo" can at neither straddle the ruts nor run in them, either of which is necessary for some sort of comfort, it is very doubtful, to say the least, if the "cyclo" ever will become popular.

**Mirrors as Viewers at Road Crossings.**—For the use of warning automobiles are commencing to be used in England, it is stated and the results are very good. They are being put in places where the crossings are especially dangerous and the use of large mirrors shows the view of the crossing from the cars which are coming in other directions. The method will probably be extended in the future, as it is likely to avoid many accidents and will be well worth the small cost of putting in. Another use for mirrors is upon heavy power wagons, where the driver sits at the front of the wagon, and the driver has to look back to see the view of the crossing. It is proposed to fit the power wagons with small mirrors showing the view of the crossing from the rear, thus making it obligatory, the mirrors might be imposed upon the usual automobile cars as well, and this would give rise to some objections from their owners.

# The Screw Spike Versus the Cut Spike

## The Tie and Rail Fastening in Their Relation to Safety of Travel

ALTHOUGH the typical American railroad track when the ties and fastenings are new and the last is of good quality, proper depth and well tamped, is an excellent construction for its purpose it is liable to very rapid deterioration, and unless the inspection is constant and careful it will quickly begin to show signs of wear and if neglected may rapidly degenerate into conditions dangerous to the traffic.

The present article has to do with the tie and rail fastening and particularly with the latter. These have not kept pace with the great increase in the weight of trains and speed at which they are run. Except for the gradual introduction of the plates placed between the base of the rail and the wooden tie in order to distribute the load and prevent the ties from being crushed down, the average American track today is the same in general type as it was fifty years ago. Its most glaring defect is the cut spike, which is nothing more nor less than a magnified nail—and it does not take the expert mind of the engineer to understand that nailing the rails which carry the heavy traffic of to-day down to a wooden tie is a practice that ought to have become obsolete many a decade ago. The cut spike is bad from whatever point we look at it. When it is driven down into the tie by the blows of a heavy sledge it does not cut a clean snugly fitting hole but instead it tears its way through the fiber producing the ragged hole, shown in one of the accompanying engravings. The result is bad in two ways. First the holding friction between the spike and the badly torn fibers of the tie is comparatively poor. Secondly the jagged hole thus opened into the tie favors the entrance of water and tends to set up a rotting action, which soon robs the tie of its already limited holding power.

In cases where the rail rests immediately upon the wooden tie, and to a low degree where tie-plates are interspersed the heavy loads of modern traffic tend to work the rail plate or the tie plate down into the tie and away from the head of the spike. Moreover the general elasticity of the rail, the ties and ballast causes the wheels of the train to produce a wavy like action which gives to the rail at any particular point a continual vertical movement. The rail is first depressed and then by its own elasticity or by the wavy like action returns to or above its original position, pulling the spike with it, and leaving them in time with the head from one to as much as two inches above the base of the rail. This condition in one of its worst forms is shown in one of our smaller illustrations. Some of our more progressive railways

have recently begun to adapt the screw fastening which has been common practice on European railroads for a long period of years. In some cases the screw spike is screwed down into place without boring of any preliminary hole, but the best practice is to bore a hole smaller than the spike, and then screw the latter firmly down into position with its head bearing snugly on the base

oak tie was 5,160 pounds and the maximum resistance of screw spikes was 13,580 pounds. The tests of Hardy Catalpa wood shows the maximum resistance of cut spike for twelve tests was 5,000 pounds and for fourteen tests of screw spikes the maximum was 9,640 pounds. Four and five tests respectively of seasoned chestnut gave 3,220 pounds resistance for cut spikes and 11,150 pounds for screw spikes. Forty tests of seasoned loblolly pine gave a maximum resistance for cut spikes of 6,200 pounds and for screw spikes, 13,710 pounds. The superior results with screw spikes as thus obtained in the laboratory have been confirmed in actual service in the tracks.

### The Color of Cocoons

THE color of the cocoon produced by certain *Lepidoptera* is the object of researches made by the German scientist, DeWitt. In the case of the *Heterocampa* genus, he observes in the case of a caterpillar kept in a tin box, that about 8 or 9 o'clock A. M. it prepares a gray cocoon formed of silk and a certain number of hairs, and it is only about 2 o'clock P. M. that it commences to saturate the cocoon with a creamy liquid which whitens and renders the cocoon hard and durable. Making a small opening, he is able to see the caterpillar spreading the liquid on the inside with its mouth, so as to be absorbed throughout the whole mass. The finished cocoon is of a light gray hue, but if this is now taken off, the caterpillar commences to make a second one, in which the silk is entirely white, and this is due to the fact that the provision of liquid has now been exhausted, so that no more can be put on and the cocoon remains in its original state. It should also be remarked that in the case of the first cocoon, after saturating it with the liquid the caterpillar then lines it with a white silk which remains in the natural state in all cases. Such cocoons when placed in water become black, and the water takes a brown hue. He also notes that the saturation of the air causes color changes, and the cocoon is almost black in damp air, but remains a light gray in dry air.

### How to Clean Brass

TWO clean brass furnishings or to remove its spots or tarnish from them they should be boiled for 4 few minutes in a solution of one ounce of alum to every pint of water. After boiling they should be polished by some brass polish or dust a dry cloth which will remove lard from all surfaces where they means fall.

These spikes have been partially drawn by vertical working of the rail.

"Shims" between rail and How rail spikes are the destroy holding power and movements of rail.

Section of tie, showing helical lining as used with screw spikes on the Harriman line.

Crushed and splintered ties, found by Interstate Commerce Commission at scene of a derailment.

Section through a portion of a railroad tie showing the bored hole, helical lining and screw spikes in place.

Section showing the brutal tearing of the fiber by driving out spikes.

of the rail. We present an illustration of a screw fastening which is being used on the Harriman roads with great success, in which the holding power of the spike is greatly increased by first screwing down into the tie a helical steel lining, of the same pitch as the threads of the spike, which are engaged by the threads when the spike is in place. This device provides a greatly enlarged area of resistance against shearing, and it is particularly valuable when the softer woods are used.

The great superiority of the screw over the cut spike was demonstrated by some tests made at Columbia University by Prof. Ira H. Woolson. In these pulling tests, it was demonstrated that the maximum resistance of cut spikes driven, without boring, into seasoned

## Lifeboats Which Can Be Launched on Either Beam.

UNTIL the time arrives when ocean-going steamships are so fully protected against sinking that every ship can act as its own lifeboat, it will be necessary to store sufficient lifeboats to take care of every soul on board. As compared with present conditions, this involves carrying twice and in some cases three times as many lifeboats as are now carried on some ships. Where such an increase is made, especially in the largest vessels, the problem of storage and the getting of the boats to the side of the ship becomes a very difficult one.

At the time of the loss of the "Titanic," the *Scientific American*, in its issue of April 27th, 1912, published a study of this problem in connection with the ill-fated ship, in which it was shown that by stowing the lifeboats athwartship and dispensing with some of the deck structures, it was possible to provide for fifty-two lifeboats instead of the twenty that the ship carried. It was suggested that in order to be able to launch the boats on either side of the ship, that is to say, to which ever side she was listed, the boats should be mounted in boat slides or cradles, running in grooves sunk in the deck of the ship.

We have been much interested to learn that the large *Flushing Royal Mail* steamer, one of \$600 tons, owned by the Netherlands State Railways and running on night service from Falmouth to Flushing, have for the past five years been making use of this method of carrying and handling lifeboats, and we present the accompanying illustrations, showing how the boats are stowed and launched. The ships of this company make it a point to provide sufficient lifeboats to accommodate every person on board. This calls for a larger number of lifeboats than it would be possible to carry conveniently in davits along the side of the ship and consequently, some of the boats are carried adjacent to the mainmast in the accompanying engraving, which represents one of the deckhouses, with four boats mounted above the level of its roof.

The two outer boats at the side of the vessel are mounted on movable boat slides, which are arranged to travel on a curved rail which spans the deckhouse from side to side of the ship.

The V-shaped boat chocks are mounted pivotally on the center of the movable slide at the top edge of the two plates which form the sides of the slide are arranged to receive eyebolts, which are placed in such position that the boat at whatever part of the rail it may be stowed and made fast will rest in a vertical position.

It will be evident from a study of this arrangement that when the center boats are to be launched, all that is necessary is to undo the lashings of the slides, make the davit tackles and slides move in to port or starboard, where it is hoisted, swung outward, and lowered. The arrangement permits all four boats to be lowered on whichever side of the ship is advisable, this, of course, being in evidence, as the slide toward which she is listed.

It should be noted that any obstacles on deck, such as hatchways, are easily overcome by building the rails above the same. In practice it takes the crew fifteen minutes to transfer half the boats from one side to the other, and to lower all the boats into the water over one side. The device was worked out by one of the company's officers and it was awarded a gold medal at an improved life-saving device by the Exhibition of Safety which was held at the Hague in 1908.

## Rescue of the Andrie Expedition

BY VOY. NO. 10 of Andrie's ill-fated balloon expedition in the Arctic was found last September floating off Prince Charles Fjord, west of Spitzbergen. Discarding this event in the Swedish journal *Tyden*, in connection with the previous discovery of bodies Nos. 3 and 4 on the southwest coast of Spitzbergen, Dr. Nathorst concluded, in view of the known course of the currents, that all three were thrown overboard to the southwest of Franz Josef Land. When all the remains, it seems certain that the course followed was first northeast and then, after a westward turn, south. The final catastrophe seems to have occurred between Franz Josef Land and Nova Zembla.

## Making the Aeroplane Safe by the Gyroscopic Stabilizer.

By Robert G. Sperry

IT is commonly recognized to-day among aviators and the builders of flying machines, that stability is the quality most to be emphasized in order to insure greater safety and wider adaptation of the aeroplane. This stability must be either inherent or so responsive to automatic control that the pilot shall be subjected to a reasonable minimum of excessive nervous stresses.

Boats of the *Flushing Royal Mail* steamer as arranged for launching on either side of ship.

Details of the rails and boat slide.

As we know, Monsieur Gustave Eiffel and his distinguished collaborator, Engineer Erawlecht have produced the "aerostable," a combination of tandem wings, which, through their measure of opposite impulses, tend to establish automatically a resultant stability in the machine which is mutually supported by them. This, in brief, constitutes the element of inherent stability by which an aeroplane of that design is steadier in flight and not so apt to tip vertically, i. e., fore and aft, because of gusty conditions of the wind prevailing at the time.

But the aerostable is only a partway solution of the problem of longitudinal stability and has nothing to do with the lateral aspect of the question which is undoubtedly the more difficult to meet. The most suc-

Diagram of the Sperry gyroscopic aeroplane stabilizer

cessful efforts to deal with these two departments of aeroplane stability have been those of Mr. Elmer A. Sperry, who has been experimenting in conjunction with Curtiss machines for more than a year. Recent trials at the Curtiss camp at San Diego, California, have demonstrated the correctness and the efficiency of Mr. Sperry's gyroscopic stabilizer. The gyroscopes as a stabilizer for aeroplanes is not, in itself, exceedingly new, but the manner in which Mr. Sperry employs its corrective agency is a novel one. In the present apparatus this measure of safety

control is not entirely the result of the functioning of gyroscopes, and this departure is one of the ingenious features of the installation. It employs a tempering mechanism which overcomes one of the serious defects which characterized earlier stabilizers using the gyroscopes, pendulum, or other inspiring medium tending to maintain horizontality. We shall appreciate the value of this modification presently.

In our illustration of the vital mechanisms of a hydro-aeroplane, the rectangular disk is the exposed surface of an anemometer. Its duty is twofold. First, it furnishes a "slide" across at every instance of the speed of the aeroplane. It catches the machine when rising too slowly and starts the flyer upon a life-saving volplane before there is danger of its sliding backward and it also serves to register the angle of the various maneuvering planes, so that the amplitude of their steering effect will just suit the speed of flight at any moment.

When climbing the aviator ordinarily knows next to nothing about the actual rate of his progress. The nose of the aeroplane points upward and his engine may be working smoothly and yet the very angle of his rise may cause the aeroplane to slow down dangerously close to the critical speed at which the air fails to sustain the machine. Before he knows it the flyer starts slipping backward and will lose instantly the aeroplane is falling uncontrollably, as hebered all first. Let us see how the anemometer comes to the rescue.

When the wind pressure on the little disk registers within a few miles of the speed of minimum buoyancy, the anemometer brings into play a small electrical apparatus trained a servo-motor, which operates a shaft leading to the lever in the system of longitudinal control. This shaft does its thing, first, it shifts the fulcrum so that the pilot cannot operate the lever and then it functions the lever itself through the medium of compressed air. In such a manner that the aeroplane is made to turn its nose upward and a number of times the machine automatically upon a gliding descent. This impulse is sufficient to bring the velocity of flight well above the critical point and in this way the aviator is warned of the danger that was near and corrects his attitude. Such a device, it is true, has probably been responsible for a number of distressing accidents. In this particular operation the gyroscopes is not an essential associate.

Ordinarily, however, the gyroscopes exercise automatic surveillance over stability, both in the horizontal and the vertical planes, by regulating the flow of compressed air to the operative cylinders. In principle the arrangement is rather simple. The motive cylinders are attached to the same crane or levers that can be worked by the pilot's hands or the lateral wing of his body against the yoke attached to the back of his seat. The hand wheel in front of him functions the vertical movement of the nose of the machine, while the lateral throw of his body corrects or guides the horizontal tilting. Both of these operations are subject to his will so long as he presses an attachment on the steering wheel and he can maneuver the machine quite independently in this manner despite the action of the stabilizing gyroscopes. But when he does not wish to supersede its guardianship of the gyroscopes, then they take over the command of all lateral and vertical movements on the part of the aeroplane and experience has amply demonstrated that these little spinning wheels are far more alert than the most skilful of aviators.

The way the gyroscopes work is as follows: when a disturbing impulse in the form of a wind just hits any part of the system of guiding planes the gyroscopes whose duty is to provide a remedy move in opposition and in this manner they actuate a wonderfully delicate balanced valve in the air supply line and motive energy is accordingly fed to the proper cylinder, the piston rod of which pulls or pushes the control lever. The wires are attached to run either to the altimeters or wing tips or to the plane at the end of the tail. But these gyroscopes have no quantitative discrimination and would cause the planes to move through a given angle, so much whether the flying machine were going fast or slow. In other words, if traveling at a high velocity, this effort to stabilize would probably produce violent motions that might throw the

pilot out of his seat and do harm when really intended to help. It is here that the anemometer comes again into play. By continually shifting the fulcrum of the intermediate cylinder or lever it gauges the measure of the angular movement, either of the altimeter or the elevator at the tail, and thus an easy steering or corrective action follows, the wind pressure on the face of the ventral anemometer producing the amplitude of the movements of the necessary pivoting fulcrum.

The electrical impulses for the signaling gun is obtained from a little dynamo driven by a belt from the forward end of the crank shaft. This motor weighs only a few pounds, and should the engine stop, there is still in reserve sufficient power for operative purposes. For a short while in a storage battery. This energy would meet all requirements incident to a descent and is automatically thrown into service when the engine hault. The manner in which this dynamo is constructed makes it possible to generate both direct and alternate current, and the latter is available for wireless telegraphy without the need incidental to a separate installation for that particular service. Compressed air is cleverly obtained by a small apparatus actuated to the head of one of the cylinders. It catches the impulse of an explosion and transmits it through a valve and a needle adjusted check valve prevents any of the explosive mixture reaching the air tank. In this manner the reservoir is kept charged at the desired pressure and a sufficient reserve is maintained, so as to provide motive power for the signaling equipment for a reasonable time after the engine ceases to work.

The previous difficulties with stabilizers has been that they dangerously hampered the independence of the pilot. Mr. Sperry, however, leaves the airman free to exercise control or to let the stabilizing equipment take to the apparatus in the interim, the aviator being as protected in command only when through ignorance or intention, danger is near. At San Diego, Mr. Sperry's son and some of the Curtiss pilots have deliberately gone out over the water and tried out the stabilizing machine and in every case the apparatus has responded to the demand and functioned effectively. This not only means a material gain in military value, but it bears importantly upon the future use of the flying machine either for sport or commercial service of one sort or another.

#### Aeroplane Accidents

SINCE the last fatal aeroplane accident in our Government service in which Lieut. J. D. Park lost his life, near Los Angeles, Cal., on the 9th of May, attention has again been invited to the large number of casualties which have followed aviation in our military service.

None matter stating statements of percentages have followed, but before relying too much upon those it may be well to note that our midwinter in having a number of casualties occurring close together, combined with the very small number of aviators which we have in our service would greatly exaggerate our situation in this respect. A far more useful comparison might be made when we consider the average number of hours in the air and miles covered per aviator. It is admitted that the percentage of casualties in our service is high, since six of our officers have lost their lives, beginning with the sacrifice of Lieut. Thomas E. Selfridge in the preliminary trials of our first military aeroplane at Fort Myer, Va., in the autumn of 1908. When we examine our records in connection with the only other nation from which exact data are available (England), we find that our aviators average nearly twice the number of hours in the air and miles covered per aviator.

The data from France include pilots of all kinds, and consequently do not furnish a basis for estimate. If we consider simply percentage of losses, Italy is ahead of us in the mournful statistics, while England is very close. There is one thing which an examination of the statistics presents, and that is the greater percentage of casualties occur in the first few flying months after which there is a marked falling off. This fact alone gives France a great relative advantage since her officers have had more training periods that average much longer than our own. Due to the exigencies of the service, very few of our officers have been available for long periods of training in aviation.

When it is considered that the United States has been able to furnish so few of her officers for this service and that such modest equipment has been provided the records of aviation in our service are causes for congratulation, rather than commiseration. Unfortunately, casualties are given much more prominent place in our publications than the praiseworthy achievements.

If we regard the latter, and recognize that aeronautics has risen to an important place among the great war establishments of all military nations, it will be admitted that it is worth the cost, regrettable as it may be.

#### Ferro-Titanium Alloy in the Manufacture of Iron and Steel

By Charles V. Stearns

THE physical characteristics and the uniformity of iron and steel have been remarkably improved by the use of titanium in the foundry. The titanium treatment tones up the endurance of steel against mechanical shock, fretting and abrasion in railway rails, chilled cast wheels, chilled rolls and the like, and enables high speed metal cutting tools to hold up structural steel.

The use of titanium alloy in iron and steel is of comparatively recent date. The successful manufacture of it was only made possible by the discovery of Bessemer using the electric furnace (which has so many metallurgical facts to its credit) after many years of experimentation with other furnaces. Since being established on a sound basis by the aid of the electric furnace, the manufacture of titanium alloy has gone ahead by leaps and bounds, a single factory now having a product of 100,000 pounds daily. The year 1910 showed an output of 325,000 gross tons of titanium steel prepared by treatment with this alloy, and this very large product was increased to 410,000 gross tons in 1911.

The beneficial effect of titanium on steel is due to the removal of gases and mold impurities in the steel. These impurities, even though present in very small amounts, mask the physical characteristics of the metal, causing it to vary widely, even while showing seemingly constant chemical composition. The titanium treatment is applied to the molten metal in the foundry and the action of the titanium is essentially a cleansing one, based on the fact that titanium is a very powerful deoxidizer, with a strong affinity also for nitrogen. Added to steel containing deleterious oxides and occluded gases, the titanium greedily and voraciously combines with the foreign substances, developing compounds which are expelled as a very fine slag and leaving the metal itself pure, clean and dense. The

Comparative wear in equal time of Bessemer and titanium rails.

alloy may be added in the ladle preferably poured directly into the stream running from the iron cupola or steel furnace into the ladle, so that the lumps of alloy (resembling so much pig iron) are thoroughly churned up in the molten metal. It is important to mix the metal thoroughly so it may be better than the fluid steel. After standing for a few minutes the ladle full of molten metal is poured into the ingot molds or into castings.

In railway rails alone the effect of titanium has been most striking because the present need of better metal support the great weight, high speeds and generally severe service in modern railway traffic. The accompanying illustration shows at a glance the beneficial effect in the lessening of wear on the head of the rail. The drawings are cross sections of two rails, the lighter 100 pounds to the yard, laid on the high or outer side of a railroad curve subject to continuous heavy traffic, and show the wear on the rails after a few months' service. The first drawing shows the original outline and the outline after the stated wear on a rail from titanium treated steel, and the second drawing shows the original and worn outline on a plain Bessemer steel rail. The treated rail in this instance has a considerably larger carbon content, but this increase is not essential to the success of titanium, and it should be noted that the titanium treatment so fluidizes the steel as to permit using comparatively high carbon that would, without the titanium treatment, cause brittleness in the steel.

#### What Are the Ten Greatest Inventions of Our Time, and Why?

A Prize Article Contest Open to All Scientific American Readers

THE November Magazine Number of the SCIENTIFIC AMERICAN is to be devoted in part to a review of the great inventions of our time. Because a large number of SCIENTIFIC AMERICAN readers are either inventors or users of inventions, it seems to the Editors that their judgment of the inventions produced in our time which deserve to be called the greatest, their appraisal of the importance of the inventions, and their suggestions of improvements of our day, would be of peculiar value

and interest. Therefore, it has been decided to leave the entire subject to them.

The publishers of the SCIENTIFIC AMERICAN offer three prizes of \$100, \$50 and \$25, respectively, for the three best articles on the topic, "What Are the Ten Greatest Inventions of Our Time, and Why?"

Contestants for the prize must observe the following rules:

1. Each article must discuss and answer the following three questions:

- a. What, in your estimation, are the ten greatest inventions produced within the last twenty-five years?
- b. What are your reasons for this selection? Justify your answer in each case.
- c. To what person or persons is the greatest credit due in the developing and perfecting of each invention which you have selected?

2. The entire subject must be covered in a type-written article not exceeding 2,500 words in length, and must be treated as simply, lucidly and non-technically as possible.

3. In deciding what are the greatest inventions of our time, the contestants are limited to machines, devices and discoveries commercially introduced in the last twenty-five years.

4. SINCE the SCIENTIFIC AMERICAN is "the weekly journal of practical information," and its readers practical business men and inventors, the articles submitted should deal only with *potentially* inventions and discoveries.

5. In order to guide the contestant in deciding what is a great pioneer invention of our time it is suggested that practical success and general usefulness to man kind be used as a test. A modern discovery may have been suggested long ago and its underlying theory even worked out mathematically, as in the case of wireless telegraphy, but nevertheless it falls within "our time," if it has been made generally accessible and useful within the last twenty-five years. But common sense should not be the sole criterion. The flying machine has not yet added millions to the national wealth, but, for all that, it is a great invention of our time. Mere improvements on well known and successful devices are not to be numbered among the great inventions of our time.

6. Contestants must not disclose their identity. Each article must be signed with an assumed name and must be accompanied with a sealed envelope, on which the assumed name is written, and in which the real name and address of the author is contained.

7. Contestants must address their articles, accompanied by the envelopes containing their real names, to "The Invention Contest Editor of the SCIENTIFIC AMERICAN, 301 Broadway, New York City."

8. The articles will be passed upon by a Board of Judges, whose names will be announced in a future issue of the SCIENTIFIC AMERICAN.

9. The Board of Judges will receive only the articles submitted, the envelopes containing the true names and addresses of the authors will remain in the possession of the Editors of the SCIENTIFIC AMERICAN. When the Judges have made their decision, the Editors will open the envelopes of the winning contestants and notify them of their success.

10. The decision of the Judges will be announced in the SCIENTIFIC AMERICAN of November 1st, 1915. The prize-winning articles will be published in the order of merit in consecutive issues of the SCIENTIFIC AMERICAN, beginning with the issue of November 1st, 1915.

11. The Editors of the SCIENTIFIC AMERICAN reserve the right to publish any discovery or invention of the SCIENTIFIC AMERICAN prize-winning articles which have not been awarded prizes, but which are deemed worthy of honorable mention.

12. While contestants are not required to supply pictures with their articles, illustrations will be welcomed. If drawings are submitted, they need not be elaborate, the staff artists of the SCIENTIFIC AMERICAN will work them up for reproduction, provided the material supplied is intelligible. Do not send pictures torn from books and periodicals, they cannot always be reproduced satisfactorily. The use of photographs in production may constitute a copyright infringement. If photographs marked "copyright" are sent, they should be accompanied with the copyright owner's written permission for their reproduction.

13. Members of the Staff of Munn & Company, Incorporated, publishers of the SCIENTIFIC AMERICAN, and of Munn & Company, solicitors of patents, are excluded from the contest.

14. All articles will be received up to 5 P. M., September 1st, 1915.

Another Aeroplane Patent.—An aeroplane shown in a patent, No. 1,065,944, to John Thomas Shapton of Newark, N. J., comprises a frame for the aeroplane, together with a sustaining plane and a balancing plane, both planes being separately connected to the frame and having a means by which they may be moved from side to side to obtain stability.

### The Bow Rudder

To the Editor of the SCIENTIFIC AMERICAN—  
Your issue of March 10th is just received here to-day, and shows a dourly interesting in the bow rudder. I spent last summer on the Lake of Thun, and noticed that the fleet of seven steamers were all fitted with bow rudders. The wheel house contained two wheels mounted on immediately shafts, the other, their relative positions, fore and aft, denoting which rudder they controlled. These ships were legitimate river or lake steamers, not double-ended ferries, and were steered by the after rudder, on the lake. At Interlaken they came in which the steamers ran forward. They were always backed down to the lake, and during that operation were steered by the forward rudder, which temporarily represented the stern. At Thun, where the lake empties and where the current is strong, the steamers are turned out in the lake and entered every first, again under the bow rudder. At Thun there are two landings, in making one of which both rudders are used, a quartermaster for either wheel. This operation seemed to give a decided sideways or crosswise motion, which may have been the reason for the current past the landing and the strong rapid.

Paris, France. WILLIAM H. BRADFORD.

### Automatic Lighting of Light Boats by Means of Solenoids

To the Editor of the SCIENTIFIC AMERICAN—  
An article in your issue of March 8th, entitled "Lighting Light Boats by Wireless," is read with great interest, and the new application of the familiar "Wireless distant control" appears to be an improvement in this case over the old system of shore control of lights on boats.

In practice, however, it will doubtless be found that additional complication is involved and a certain degree of reliability sacrificed, also the installation of wireless transmitters and receiving devices on boats will be an additional expense which will not meet with favor.

If it is the object to avoid the old system of shore supply and control to light boats and further locate the source of power in the boat itself and do away with the wireless transmitter, the writer suggests that boats contain the necessary batteries, also a solenoid coil and relay. By this method we do away with not only the cable, but also with the proposed wireless apparatus, and have a purely automatic signal which will need occasional renewal and inspection.

It seems hardly possible that this application of the "solenoid coil" is new, but since it appears a great simplification of the newly proposed German system, and since no mention of it is found, this idea is respectfully submitted and may be taken for what it is worth in the estimation of those familiar with the light-boat problems.

The above system is, of course, applicable to many modifications, for example, control by means of a ship or shore flashlight. A KALLIOPE SLACK  
Brooklyn, N. Y.

### Undamped vs. Damped Oscillations

To the Editor of the SCIENTIFIC AMERICAN—  
My attention has been called to certain publications that have been made in your Journal of late in which the statement has been made that the result of the Navy test on radio-frequency, as conducted between the Livingston station and the cutter, was that the undamped operation, of the undamped oscillations over the damped oscillations, or, as it has generally been spoken of in the press in discussing these tests, of the oscillations from an alternator as contrasted with those of a spark generator. While it is perfectly true that superior results, for given amounts of energy, were secured with the undamped oscillations, over those secured with the damped oscillations, the real cause of this superiority has not, I believe, yet been noted in any of the papers mentioned. I therefore wish to call your attention to the fact that this superiority was shown when using the Poulsen receiving apparatus supplied to the cutter "Bulwer" as part of its equipment in connection with the spark equipment supplied by the National Electric Signaling Company. It was a fact well recognized by the engineers of the company that the heterodyne would work to its best advantage with undamped oscillations, it having been invented and developed for that specific purpose and adapted to the specific type of wave that it was well known by them that it supplied the best known receiving mechanism for undamped oscillations. This superiority was so great that after the first few days all other forms of receiving apparatus were abandoned by the Navy officials in their test of the undamped oscillations. The heterodyne receiving apparatus operates

upon the principle of "beats" in which interference beats of adjustable frequency are produced between the incoming oscillations and those produced in a local circuit. It is thus possible, in view of the action being a resultant of two forces, one from the sending station, and one produced in the local circuit, to considerably increase the available for operating indicating mechanism for receiving the signals. It is also possible by adjustments at the local circuit to secure a pure flute-like musical tone of any desired pitch and this allows the operator to select what he will like to hear. This note was not made in the interest of accuracy in order that readers interested in this line of work may be made aware of the real cause of the superiority shown by the Government test.

Pittsburgh, Pa. RALPH M. KINTNER.

### Submarine Mountains

To the Editor of the SCIENTIFIC AMERICAN—  
It may be of interest to some of the readers of the SCIENTIFIC AMERICAN to know that there are mountains and valleys under the sea, the former the surface of one of which I will describe. While acting as second officer of the U. S. cable ship "Lacum," stationed at Manila, P. I., we were ordered to proceed to Zamboanga, and run a line of soundings from that place to Zamboanga. These two important military stations are separated by a distance of 100 miles, and it was the intention of the department to run a new cable between these two places. After leaving Manila we steamed slowly toward Zamboanga, taking soundings every thirty minutes, and at the end of each day. The morning of the day from the time we left Manila until we were off Lagan-gang Point, where we got 800 fathoms, when we ran in the crew's net found out "Shoal ahead." We immediately took bearings and fixed the ship's position on the chart, but did not see anything like the mountains that resembled a shoal or anything like it, so we slowed down and proceeded, stationing a man at the lead, and when directly over the shoal spot we got six fathoms up and down from the bridge. It appeared to be a circular spot about 100 feet in diameter and of coral formation. We only got one cast of the lead when we were in deep water again, so we came to the conclusion that we had run over either a submarine volcano or mountain for nothing short of a good-sized mountain or some other kind of formation could give such a sudden change in two or three feet, as sounding a few minutes before we arrived over the shoal spot gave 800 fathoms taken with the patent sounding machine.

Cape May Point, N. J. ALBERT R. REDFERN.

### Ignition Devices

To the Editor of the SCIENTIFIC AMERICAN—  
The writer, a reader of the SCIENTIFIC AMERICAN for many years, has just noted with interest the article, "Small Internal Combustion Engines on Land and Water" in the April 8th number.

The fifth paragraph in this article would lead one to believe that the high-tension magneto was the best ignition for stationary and marine engines and offered a complete solution for their ignition troubles.

You may be interested in knowing that from careful investigation, we find only about 40 per cent of the stationary and marine engines now being made are equipped with jump spark (high-tension) ignition, this including both battery and magneto. If engines already in service are counted, the make and break engine outnumber the jump spark three to one.

As your correspondent is no doubt aware, the principal reason for the adoption of the high-tension magneto on the automobile was the difficulty in timing four make-and-break ignitors to operate in correct relation with each other and a common source of current. This objection does not hold good in the case of a single-cylinder engine, which represents by far the majority of power units in the stationary and marine field.

As to the comparative efficiency, from a purely lighting standpoint, there can be no question but that the make-and-break is far the superior. The spark is more dynamic in character, and is hotter. The make-and-break system is most successfully used in connection with low-grade oils and gas-producer units, where the ordinary high-tension, jump-spark plugs rapidly show serious deposits.

The most simple ignition device imaginable is a low-tension engine-driven alternating-current magneto. This machine has no commutator and brushes, no time contacts like the high-tension magneto, it has a single winding on the armature, requires no oil, switch or other auxiliary apparatus, is built into the engine, thereby forming a part of same, and eliminates entirely the complications of battery or high-tension magneto ignition, and at the same time furnishes a vigorous spark suitable for lighting the kinds of low-grade fuels.

We can cite to you several instances where, since the advent of this type of magneto, manufacturers have abandoned the jump-spark system and gone back to the make-and-break. This is especially true on single-cylinder engines where the high-tension magneto is absolutely no advantage and, in fact, has several drawbacks. Of course, where there are a number of cylinders, the cost

of the make-and-break igniter mechanism would be greater than the jump-spark magneto and plugs.

We believe after exhaustive investigation that it is the source of ignition that will eliminate the ignition problem in stationary and marine units. The high-tension jump spark has its field, but it does not belong in connection with small internal combustion engines, for many reasons. H. R. VAN DEVENTER.  
Sumter, S. C.

### Straightening the Mississippi River

To the Editor of the SCIENTIFIC AMERICAN—  
Notwithstanding all that has been written by correspondents in the SCIENTIFIC AMERICAN opposing the policy of straightening the course of the Mississippi River, I feel confident that this method, together with a system of levees as advocated by the SCIENTIFIC AMERICAN, is the most practical of all the suggestions yet made.

The actual distance from Cairo to the Gulf is about one half the present length of the channel from Cairo to the mouth of the river. If this channel should be straightened to two thirds its present length, the pitch per mile and the consequent flow in miles per hour would be increased one half. The product of those factors gives us a theoretical capacity of discharge to the Gulf of twice that of the present. The facts at present I am fully aware of the fact that theory and actual practice are often separated by real, or seemingly impractical, barriers. Great obstacles are, however, often overcome by Nature herself when directed by human skill, which in the present case may doubtless be applied so as to make the force of the current do the bulk of removal. For instance, a loop of the river may be cut out by digging a deep, straight and narrow channel through the alluvial soil to start the current, and if necessary may be further aided by building booms, or causeways, etc.

This straightening of the course of the flood channel would surely be a long, gradual, and expensive engineering feat, but it would accomplish results for the lower Mississippi region far more effective than the reservoir schemes.

However, I believe that much of the real livelihood should be allowed to be overflowed at each flood season. Senanton, Pa. CHARLES H. FUGGERT.

### Control of the Mississippi

To the Editor of the SCIENTIFIC AMERICAN—  
I have read with considerable interest the letters that have been sent in on the flood problem. As the editor of the *Boat and Shore Recorder* remarked in the May 3rd number, it is not a question of the dam, but I hope I can see a little farther than some.

I will agree with Danville, Ind., on the reservoir proposition. Suppose there were a half dozen reservoirs in the Mississippi valley, where would the surplus water go in a flood like the one we had in this country in March? It would be all right if it rained only a few miles on each side of the river, then reservoirs would hold the damppness, but when the Mississippi dumps one-half or nearly so of the United States it is quite different. While Plains, N. Y., thinks that a dam every few miles on the Mississippi would cost only a few dollars, the channel would be in a fine shape with its dams. The old river would be one long string of rapids, which would benefit no one. And again, suppose the dams were there, would that keep the flood from the cities? No!

Littleton, Del., says it would be a snap to straighten the Mississippi. Yes, it could be done, but what good would it do? Say it is as straight as a string from St. Paul to the Gulf and wide and deep enough to carry the highest floods. How long would it stay straight? In the first high flood season, or may be a couple of years, which I doubt why? Because on one side the bank would cave or a pocket would form. That would have a tendency to form a cross current, and the channel up against the other bank would go another pocket. So in a few years it would be as crooked, if not more so, than it is now. We will suppose again that the whole river flowed in a channel of rock. Littleton, Del., would be in the swim. Who ever lived in a "runway"? The water would be so shallow that the bottom of the interior must have been thinking of muskrats or beavers, as these animals use "runways." Plattburg, Barrens, N. Y., should know that there is a slight difference between the Kaw River at Kansas City and the Mississippi. He said that the latter is straighter than the former. The Kaw might have choked in 1904, but that is ancient history. He should keep up with the times. Everyone knows, or should know, that bridge abutments retard a river over so little. Bridges go out only when they are too high to get up. Then the water is something else to it. It seems to me that dykes and retreating would be the best. It doesn't look fair to tax the land that abuts a river and not the plantation or farm back of it. If I lived five or more miles from a dyke I should like to know where the high water would stop. It would be built large and better. I have no fool suggestions to give, as there have been too many of that kind at it in

Thoreville, Ohio. JACK HILL.

Fig. 1—The kite reel and the camera attached to the wire.

### Photography from a Kite

By A. C. Gault

WITH the idea of awakening an interest in the fascinating position of aerial photography the following experiences of the writer are recounted. It is hoped that they may prove of value as well to others who have tried to take photographs from the bird's point of view.

The kite which the writer employed is similar to those used by the United States Weather Bureau, known as their "moderate wind" type. It is illustrated in the picture showing the kite reel and other apparatus mounted on a rude home-made cart ready for transportation to the field. The kite contains 68 square feet of supporting surface, but I find it necessary to use a tall to secure sufficient stability to prevent blurring the picture. It is flown by means of a piano wire, No. 12 (0.020 inch in diameter). There is about three quarters of a mile of wire in the reel, but the kite would carry out more in a strong wind.

The camera is a specially constructed home-made affair combining with a double plate holder, about two pounds, and taking a 5 by 7 picture. To prevent excessive oscillation it is secured to the kite string or wire six hundred feet or more from the kite. Methods of connecting it to the wire are shown in Figs. 1 and 2. That shown in Fig. 4 is preferred. A description of it is hardly necessary as it can readily be made out from the photograph. It will be evident that the bracket is universal, permitting the camera to be pointed in any desired direction. The photograph Fig. 2, shows the town of Delmar, Iowa, as viewed from a height of about seven hundred feet. In making this exposure the shutter was released by means of a piece of burning punk placed in the aluminum box shown in Figs. 1 and 4, under the bellows of the camera near the forward end. This box was used to prevent the wind from extinguishing the fire. The length of time elapsing before an exposure was governed by the length of punk employed which burned through a thread thereby releasing a rubber band that sprang the shutter. In taking the photograph, Fig. 4, a clock mechanism was substituted for the punk and an improved carriage was employed for the camera. By this means the exposure could be made at any desired time and the camera could be pointed in any desired direction by a few adjustments which could be made in a fraction of the time required by the other method. The details of this mechanism and the bracket are not disclosed in this article, for the reason that they have not as yet been patented by patent. The photograph shows a stone quarry. The garage at the lower left hand corner looks rather flat. Note the crack in the upper part of the picture and the bridge at the extreme left, also the patches of snow one at the foot of the hill and the other near the edge of the quarry at the lower right hand corner of the picture. The photograph was taken from a height of about three hundred feet.

Before making with any considerable success in kite photography I made a large number of experiments in timing the exposures. A string attached to the camera shutter may be used when the camera is not high above the ground, but at any great altitude the pressure of the wind against the string is apt to cause a premature exposure. I have set off a camera by means of a trigger which sailed up the line and struck a projecting spur on the camera carriage; but this method resulted in blurred pictures, owing to the shock of the collision. I have also attached a sail to the camera and carriage allowing the whole apparatus to sail up

Fig. 2—Kite and camera on route to the field.

Fig. 4—The preferred form of camera bracket.

Fig. 5—Looking down on a quarry from an altitude of 300 feet.

Fig. 3—View of Delmar, Iowa, from an elevation of 700 feet.

the line until a projecting spar struck a piece of tin secured to the wire, when the exposure was made. The sail was then released and the camera slid down the line ready for another trip. But the pictures thus taken were very badly blurred, and the scheme was eventually given up after the camera struck the projection so hard as to be detached and hurled to the ground from an elevation of 1,700 feet. Fortunately, nothing was injured but the camera itself, although it fell right in town. Electricity has not been tried by the writer, as it calls for too great a weight of wire and insulation.

In spite of the experience of others who have taken photographs from kites, balloons, high buildings, etc., all of whom advised extremely short exposures, the writer has made dozens of exposures on bright sunny days, during the brightest part of the day, giving them one twenty-fifth of a second at F/8 or U.S.A. with absolute failure, although enough details were visible to show that the shutter had opened. This was true even with very rapid plates.

### The Submarine Violin

THE Navy Department has adopted a "submarine violin" for the transmission of messages between submarine torpedo boats and shore stations or other vessels. Exhaustive tests of the apparatus have been made on a submarine at Hampton Roads, Va., and three sets of the signal device have been ordered to be placed on many vessels.

The mechanism is an adaptation of the violin. From one side of the submarine project two steel stays. From the ends of these is stretched a plain wire. Touching the wire is the roughened rim of a wheel which, when it revolves, sets up vibrations in the wire. The wheel is controlled by a motor inside the hull of the submarine and the motor, in turn, is controlled by a Morse key. When the key is pressed the motor begins to revolve, the exterior wheel scraping the wire precisely as a bow agitates a violin string. The hull of the submarine acts as a sounding board. The key is used precisely as an ordinary Morse key and dots and dashes are hummed on the wire as the key is depressed and released. About eight words per minute is the best speed so far attained.

The receiving apparatus is the ordinary telephone receiver. The end under water may be connected by insulated wires to a fort, shore station or another vessel.

The experiments at Hampton Roads showed that the vibrations may be heard clearly at a distance of five miles. Naval officers believe that the device can be perfected so that the range of the mechanism may be greatly extended.

Christian Berge, an Austrian, is the inventor of the submarine violin. He attempted to get the Austrian government to make tests of it, but failed. Coming to the United States, he succeeded in convincing Navy Department officials of the practicability of the scheme.

The signal is a simple device and does not get out of order easily. It is available at all depths. It is expected to add not only to the ease of communication with submarines operating in harbors or in close proximity to war vessels in time of war, but will add materially to the safety of the men who go down in submarines that meet dangerous type of war vessels yet service.

The Linnæan Geographical Society, one of the best-known organizations of its kind in South America, will celebrate the twenty-fifth anniversary of its founding on February 22nd, 1914.

# **A New Way of Making Artificial Diamonds** by the Electric Furnace

**PARIS** engineer, M. A. de Boismont, claims to have synthesized small diamonds by a new electric furnace method. It will be remembered that the late Prof. Moissan succeeded in obtaining very small diamonds (of microscopic size) in the electric furnace, but the process required special skill, and in any case the results were merely of scientific interest. M. de Boismont employs a new principle, which has the advantage of being very easy to carry out in practice by a skilled operator. Moreover, the process will undoubtedly be further improved so as to secure larger specimens than those so far produced, which range up to 2½ millimeters in diameter.

The inventor occupies a prominent position as director of an electric carbide furnace plant in France and conceived the idea that the diamond could be produced by electrolysis of a bath of molten carbide between the usual carbon electrodes.

The furnace used is built of refractory brick and has two carbon electrodes ½ inches in diameter, one of which can be adjusted by hand. The bed of the furnace is first packed with a mixture of powdered lime and carbon, which serves to hold a trough shaped receptacle made of fused calcium carbide, as this is found best to hold the molten bath within the furnace. The carbons work within this trough, and are packed around with rather large fragments of carbide. By leaving the current on the bath of molten calcium carbide for a number of hours, an electrolytic action takes place by which the carbide is decomposed and the negative pole becomes surrounded by a black carbonaceous mass, in which are found embedded small crystals. These crystals answer to all the tests for the diamond.

The first consecutive operation was made on April 18th, 1908, in the inventor's experimental laboratory in the suburbs of Paris, using direct current from a small dynamo plant therein installed. After heating up the electrodes, they were drawn one inch apart, and calcium carbide was gradually fed in in small lumps, so as to produce a molten bath. The carbons were then gradually separated until finally they were 10 inches apart. The heat commenced at 11 A. M. and ended at 5 P. M. with a continuous run of 6 hours. The current used was 800 amperes at 24 volts. There were 8 pounds of melted carbide in the bath. At 8 o'clock a pile of carbide fragments were heaped upon the bath, and the whole was covered with a mixture of equal parts of lime and carbon so as to stop up the interstices, and finally the furnace was covered with two refractory slabs. The furnace ran in this way up to the end of the test, when the current was stopped and the furnace allowed to cool off over night. The carbonaceous mass resulting from this operation, weighing from 600 to 700 grammes, was

placed in a vessel of water and allowed to remain over night. The residue was examined the next morning. During the night it had disintegrated in the water and formed a black mud, which was decanted and then slowly dried over an alcohol lamp. At once M. Boismont's attention was attracted by small brilliant points standing out against the black background. He was

who were unable to distinguish them from natural diamonds. One of the largest specimens could even be cut, and the author sent it to Amsterdam for the purpose. It was returned cut with thirty-two facets with remarkable clarity.

M. Boismont hopes to be able to continue his experiments in the near future, providing that funds are forthcoming for installing an electric furnace plant upon a larger scale. In closing we should mention that the process has been patented by its author.

Diamonds obtained in a nine hours' run. Magnified six diameters.

From ten hours' run. Enlarged nine times.

Some of the results of a twelve hours run. Enlarged six diameters.

Diamond obtained on June 3rd. Enlarged fifteen diameters.

Carbonaceous furnace product in which diamonds are found embedded.

## **Diamonds produced in the electric furnace**

able to pick these particles out by forceps and thus separated about a dozen of them. They appeared as small transparent crystals of somewhat irregular shape whose size varied from ⅓ to 1½ millimeters. Under the microscope they showed the characteristic appearance of diamonds. The specimens will scratch a plate of glass under very slight pressure, and the scratches are deep and remarkably clear. Steel can also be scratched by them.

From April 20th to June 5th the furnace made fifteen runs, of which eleven were very successful. The last two of these, the furnace ran for 12 hours with 700 to 800 amperes at 24 to 25 volts, and some of the crystals reached one tenth of an inch in diameter. This seemed to be as far as one could go with the present small plant, and a new one will be required for further work. The specimens were submitted to two jewelers of Paris,

balcony that projects only a couple of feet beyond the wall of the house. It is protected by a railing and an insect-proof screen. By day the bed is covered by a dome of metal that protects it from the weather and at night when the couch is in use, the occupant shifts the dome to the inner side of the bed so that the outer side is uncovered. In case of a rain coming on during the night, he can swing the dome back to its original position without getting up. For protection against light showers heavy dew and morning light a waterproof curtain is provided, that is drawn down to any distance following the curved line of the screen. This also secures privacy in the morning. For the convenience of nocturnal rest, a bulb is placed over the head of the bed. For making up the couch the whole body can be drawn into the room, and as readily rolled back into place. Then a few blinged parts are unfolded and an attractive "built in" divan occupies the place where the bed is concealed. This provides the advantage of the ordinary folding or disappearing bed by adding a living room, for use by day to a small apartment. The device is installed in various private homes and apartment houses on the Pacific Coast.

## **Hints in Varnish Making**

**TRANSPARENT** varnishes or inepars are readily made by dissolving gum copal or gum dammar in the proper solvents. However, it is not generally known that the solubility of gum copal in alcohol is greatly increased by first melting the gum. It flows about twenty per cent water by this treatment and changes its properties. In fact it becomes much more soluble in turpentine. It should be melted at as low a temperature as possible or black specks will appear

By separating the bed from the room the bed is rolled into the alcove.

The bed is built up as a shallow balcony.

By unrolling a few blinged parts the bed may be converted into a divan.

**A bed in the open for city dwellers.**

## Safety in Travel as Affected by the Steel Rail

### The Problem of Producing a Rail Which Will Stand Up Under Heavy Modern Traffic

SO far as the mechanical or material side of the problem is concerned there is no single element upon which the safety of railroad travel depends so greatly as it does upon the steel rail. Also it is certain that there is no single element which is subjected to such brutal treatment in its daily service or that is called upon to resist such varied and destructive stresses as this important member. Furthermore it is certain that the work imposed upon the rail has at least doubled during the past two decades. Not only must it wear as a true plane surface to receive heavy and swiftly moving loads but it must act as a continuous bridge carrying these loads from tie to tie and often because of inequalities of the graded supporting the same loads over distances measured between several ties. The steel rail is subjected to severe compression in the height of the summer weather and equally severe tension during the cold of winter. It is exposed to bending twisting and shearing stresses in every conceivable direction and of constantly varying amounts and these stresses frequently occur with rapid reversals. Finally it is subjected to hammering blows from poorly balanced locomotives which at no call for a very high quality of material.

In the early days of railroading when speeds were lower and weights upon individual wheels were not one-half what they are to day it was possible to use a tough and ductile rail which possessed sufficient hardness to stand long service without being crushed by the traffic. Of late years however the weights of engines and cars have gone up by leaps and bounds and continuing rapidly with this increase has been a great increase in the average speed both of passenger and freight trains. The earlier and comparatively soft rails failed to stand up under these loads and the composition was changed so as to include a larger percentage of carbon giving a corresponding increase in the hardness. With this advantage came the disadvantage of

increased brittleness and while the high carbon rail is no longer battered down under the heavier traffic it became more subject to breakage.

Rail head split by the cold rolling and welding action of heavy concentrated wheel loads.

It is the purpose of the present article to give a condensed sketch of the present methods of rail manufacture as generally followed in this country and to point out the lines along which improvement is being sought and in some cases realized.

In the manufacture of the steel from which rails are rolled there are two principal processes: first, the reduction of the ore in the blast furnace; second the conversion of the molten iron into steel either in the Bessemer converter or in the open hearth furnace. The raw materials of manufacture consist of iron ore, coke and limestone in proportion of two pounds of ore to one pound of coke and one third of a pound of lime-

stone. The ore is reduced in the blast furnace a huge steel shell brick-lined which varies from 75 to 90 feet in height. The materials are loaded into bins back of the blast furnaces from which they are drawn off into skip hoppers and by them carried to the top of the furnace. Here the contents are discharged into a cone shaped hopper from which they descend into a second hopper immediately below it with space between forming a chamber on the principle of the air lock. By this arrangement the escape of gases from the furnace is prevented. When the lower hopper is opened by lowering its cone the materials fall evenly over the top of a charge already in the furnace. From the top of the furnace the gases are conducted by a large steel pipe to a set of four or five hot blast stoves filled with fire brick, where they are ignited and serve to raise the brick to a high temperature. The air blast for the blast furnace is passed through the heated stoves, and the air as thus heated to a temperature of 1,000 to 1,400 deg. Fahr. is conducted through tuyeres into the bottom of the blast furnace. About one third of the gas produced is required to heat the stoves and the remaining two thirds is used either as fuel under the boilers to generate steam or as in the case of the Gary Steel Works used directly in large gas engines. At the Gary works the power so generated is used in the rail mills, merchant mills, bridge works and mills for rolling steel sheets.

When once a blast furnace has been started it is maintained day and night in continuous operation. The temperature ranges from about 500 deg. Fahr. at the top of the furnace to 2,000 or 2,500 degrees at the base. The molten iron and slag collect at the bottom of the furnace from which they are cast into ladles mounted upon trucks each of the ladles being capable of holding as much as 50 tons of hot metal. The ladles are drawn in trains of five or six to the mixer—large iron receptacles capable of holding from 400 to 600 tons of

Pouring a heat of steel from a Bessemer converter into the ladle.

Electric furnace tipped over and discharging into the pouring ladle.

Eleven rails lifted at once by the electro-magnetic crane.

The hot saw cutting the finished rail into rail lengths

molten metal—from which it is discharged as required into trains of ladles and taken either to the Bessemer converters or to the open hearth furnaces.

Up to this point the product is simple molten cast iron which, if run into molds would form the common cast pig iron of commerce. From this point on the process is one of converting the cast iron into steel of the required composition and quality.

Hitherto, steel for rails has been known either as Bessemer or open hearth, these two being the main processes employed in the production of steel in such large quantities as are required for steel rails. During the past few years, however, thanks to the enterprising of the United States Steel Corporation it has become possible to produce rail steel in commercial quantities by the use of the electric furnace—a subject to which fuller reference will be made later in the present article.

The famous Bessemer converter is a barrel-shaped wrought iron or steel vessel lined with refractory materials and carried on trunnions through which an air blast is conveyed to the bottom of the converter which it enters through some two hundred separate half-inch air holes. The converter is swung over in the direction of the ladles of hot metal and charged with about fifty tons. The air blast is turned on and it is then swung into the vertical position. As the air rushes up through the molten mass, the oxygen combines with the carbon silicon manganese etc. in the iron raising the temperature to about 5,100 deg. Fahr. or 700 to 800 degrees higher than at the beginning of the blow. In eight or ten minutes time all the impurities and practically all of the carbon have been burned out leaving only nearly pure iron. As pure iron is a comparatively soft metal so soft in fact that it may be cut with a pocket knife it is necessary to combine with it elements that will produce the requisite degree of hardness to resist the crushing and abrading so fine to which the rail is subjected. The most available substances for the purpose are carbon and manganese about one half of one per cent of the former and one per cent of the latter, being the proportions generally employed.

The converter is then swung over on its trunnions and its charge is emptied into a fifteen-ton ladle and at the same time a certain amount of molten spiegeleisen is poured into the ladle with the iron the proportion being such as to introduce into the metal the proper amount of carbon and manganese for the quality of steel rail that is to be made. The hot metal is then drawn off from the bottom of the ladle into a series

of rectangular cast iron ingot molds measuring about 22 inches square in section and about six feet in average height.

In the open hearth method the metal from the mixer is poured into large closed furnaces, each furnace in the later and most modern plant containing as much as ninety tons. A certain amount of steel scrap iron ore and limestone is added. The charge is then sub-

Section through a fifteen-ton electric furnace

jected to the fierce heat of burning gases which enter at one end of the furnace pass over the charge and leave through flues at the other end. From time to time samples are taken from the furnace, and tested. The ultimate object of this treatment is the same as that of the air blast in the Bessemer converter and although the operation consumes much more time it possesses the advantage that by means of it certain grades of metal not suitable for making Bessemer steel can be utilized. The impurities are allowed out of the metal and the various alloy additions are made

until the proper percentage of carbon, manganese etc. for the particular grade of steel that is being made has been reached. The metal is then ready for pouring into the ingot molds.

The process of rail making as thus far described applies broadly to any large rail making mill. The description is that of a mill based upon a visit recently paid to the works of the Maryland Steel Company and applies particularly to the methods followed at that plant, the rails from whose mills have shown particularly good results during the past few years. The excellence of the product is due largely to the good quality of the Maryland ore which comes from the company's mines in Cuba. These ores contain nickel and chromium and are unusually low in the deleterious phosphorus. In addition to possessing excellent ore the company at this works pays particular attention to the input treatment.

At the Sparrows Point mill special effort is made to reduce segregation (that is the tendency of the constituents of the steel to separate out during the cooling of the metal) in the ingot mold and in fact certain ladles in which these separated constituents are concentrated. Nothing not even the pipe itself is considered steel more useful in its destroying the quality of a steel rail than segregation. To prevent or reduce segregation the metal is poured into the mold at as low a temperature as possible in order to facilitate early solidification and the ingots are placed in the soaking pits as soon as possible after they have been cast in order to conserve their heat as well as to produce a better surface on the rail. In the soaking pits the temperature of the ingot is equalized and it is then taken out and given thirteen passes through a thirty-six inch blooming mill in which it is reduced to eight by eight inches in section. Nine per cent of the original length is cropped off to remove the pipe and segregated material and the blooms then go to a 27 inch rail mill where it makes six passes in the first four in the intermediate and passes through the finishing rolls. In the finishing rolls the brand mark is rolled into the rail as is also the number indicating the position of that rail in the original ingot. The rails are then run to the hot bed and allowed to cool. From the hot bed they go to the straightening press after which all burrs and irregularities are chipped off and the sides bar holes are drilled in the ends. It should be explained here that the rails are cut to length in high speed circular saws and that they are cut sufficiently longer than they

(Continued on page 828)

**THE JOURNAL OF THE**

### A Safety Parachute for Airmen

**A**LEX STEVEN of New York city has invented a novel compact safety aeroplane parachute. F. R. Law and Arthur Lapham with its aid have made all sort of leaps into space from bridges, built huge spinning aeroplanes, exploding balloons and the like without mishap.

As shown in our illustration, the parachute is rolled up into a pack worn on the aviator's shoulders like a knapsack. It is wrapped in a square piece of cloth which when the parachute opens remains with the harness of leather straps by which the aviator is supported. Instead of the harness which was used by Law, a leather belt is all that is necessary.

When made of Japanese silk this new safety parachute weighs only  $4\frac{1}{2}$  pounds complete. It is 16 feet in diameter and is attached by 10 Italian hemp ropes to a spreader bar of steel tubing filled with hickory, which is located 15 feet below the parachute when open. A wire rope having a breaking strength of 24 tons is secured to the spreader and the supporting ropes are fastened to the strong cable. Two additional ropes two feet shorter than the main ones run to the 12-inch hole in the center. These ropes receive the initial strain when a drop is made, assure the proper opening of the parachute, and put an equal strain upon the top by drawing down upon it. The rush of air against the folds, however, is what really opens the parachute. So sensitive is it to this, that it is designed to open within 100 feet. The jumper also holds in his hand a small cord, by pulling which he opens the parachute in case he has only a short distance to fall.

On the assumption of the aviator when his machine is suddenly relieved of 100 pounds weight, Mr. Harry R. Brown has this to say:

"When I reached an elevation of 4,000 feet, I motioned to Law to prepare to give me a return notice of the hand indicating that he was ready to go. I nodded my head and away he went. I saw no more of him until I reached the starting point some eight minutes later when I was notified that he reached the earth 24 minutes after making the leap. As he released his weight from the moving machine, I felt myself go up rapidly and the machine acted very much as if it were suspended by a cable and was being pulled up rapidly by jacks. This lasted for perhaps ten seconds. The machine all this time was on an even keel."

That such parachutes are not an absolute provision against accidents which may prove fatal, is shown by the harrowing experience of Arthur Lapham on May 20th at the Aeronautical Society's flying carnival, held at Oakwood Heights, Staten Island. With the Stevens pack upon his back, Lapham was to drop a mile from a Wright biplane piloted by H. B. Brown. At a height of a few hundred feet—three hundred, according to some spectators—instead of the promised mile, Lapham slid from his seat and shot down. The parachute did not open, probably because the drop was too short. Fortunately for Lapham, he landed without injury on the marshy salt meadow that near Prince's Bay. He was hurried up to his airplane in time and had to be dug out.

### Over \$100,000 in Prize Money for a Safe Aeroplane

**A**CCORDING to *La Nature*, the Union for Safety in Aeroplanes of Paris is to hold a contest in order to recompense the inventors of apparatus which will bring an important contribution to the security of heavier-than-air machines. The funds for prizes have already been subscribed, the sum actually raised being \$52,000 francs (\$114,400). A main prize of 400,000 francs (\$80,000) will be given the inventor of a machine or device that, in the estimation of the judges, has an exceptional interest from the point of view of safety.

This grand prize will not be divided, in addition to it other prizes aggregating not less than \$100,000 more will be given to other inventors of important devices. The judges consist of fifteen members, ten of whom are named by the Union and by the Minister of Public Works, one by the Minister of Marine, and three by the Minister of War. It is to be hoped that the latter sum subscribed will

be the means of stimulating the solving of the problem of safety in aeroplanes.

### Red Light as a Preservative of Milk

**I**NTERESTING experiments have recently been made concerning the influence of red light on milk. That light as such is detrimental to the conservation of milk has long been known, but which of the rays really did the mischief has only now been determined, when it was found that the red rays are beneficial, while those toward the violet side of the spectrum caused the milk to "turn." Pure, fresh milk placed in an uncolored glass bottle in the full sunlight, and sterilized and pasteurized milk, placed also in uncolored bottles in the same place were found at the end of the day to be completely spoiled and unfit for consumption.

Absolutely no difference could be detected between the ordinary "fresh" milk and that which had been sterilized—both were equally bad. But if even unsterilized milk is placed in a red bottle or in a bottle wrapped in red paper in the full sunlight it keeps perfectly good for ten hours. In Holland much care is being expended on delivering pure milk to the public. The "fresh milk" is brought around by the milkmen in large, covered, brass vessels placed on small hand-carts. On these same hand-carts are open holders to contain the bottles of pasteurized or sterilized milk, which costs rather more, but to which many people give the preference, as it is considered more hygienic. Now, however, that experiments have proved how easily even this pure, sterilized product "turns" by the influence of the light, it may soon be expected that every dairy will adopt red bottles. Until a sufficient quantity of such shall have been manufactured, the bottles will be wrapped in red paper.

### The Electrical Stimulation of Plant Growth

**T**HE question of increasing the growth of plants by applying electricity in various ways is one which is being discussed at present. One of the principal workers in this direction in France is Liéht Bast, and he is now engaged in making some very interesting experiments upon the growth of crops. The excellent results which he obtained have attracted the attention of the Agriculture Department, and the minister is now having the matter taken up from a scientific standpoint. Liéht Bast is now proceeding in his experiments, upon the basis that the atmosphere is an inexhaustible source of electricity, and on the other hand physiologists assert that the electrical effect serves to hasten and also regularize the circulation of liquids in the capillary tubes, such as those of plants. If we cause electricity to act on the stalks or roots of a plant, the circulation of sap is stimulated and made more regular, so that the growth of the plant is more rapid and the assimilation better carried out, hence the production from the plant will be more abundant. This idea seems to be borne out by an actual increase in the amount of crops which the author finds. He collects atmospheric electricity by small lightning rods which consist of simple iron rods ending in a non-rusting point. For vegetable gardens, the rods should be about 3 feet high, but for field crops such as wheat and other cereals, hemp and the like, the rods should have 6 feet height. The diameters are from  $\frac{1}{4}$  to  $\frac{1}{2}$  inch, and the rods are driven in the ground for 8 or 10 inches, according to the length of the roots of the plants. It is found that the action is exerted on a radius on the surface of the ground equal to the height of the rod. In practice, the cost of such rods and the labor in mounting them is very small. The following table shows the increase for the increase in the growth of certain crops may be seen, according to the length of the rods of the plants, but they are given on good authority. For potatoes, instead of 100 pounds as before, he now obtains 125 pounds. Beets show 155 pounds. Beans, for the stalk, 265 pounds, against 100 pounds in all.

Lapham just after jumping. The parachute opens in a few seconds.

## Safety in Travel

More glowing tribute cannot be paid the accuracy of the modern watch than this—in all the complexity and immensity of railroad traffic hardly a single life is imperilled, or a dollar lost, because of imperfect timekeeping. Remembering then that the

## Hamilton Watch

"The Railroad Timekeeper of America"

Engineer Lewis C. Henry of the Penn. Ry. Co. is one of the many railroaders who carry Hamilton Watches and have carried them for years.

is carried by over one-half (56%) of the railroad men on American railroads where Official Time Inspection is maintained, it is only fair to assert that the Hamilton Watch has played no small nor uncertain part in ridding travel of one of its greatest dangers—danger arising from inaccuracy of time.

Trains are dispatched on "hair-line" schedules by Hamilton time—because Hamilton time is "travel safe."

Hamilton Watches are made in correct sizes for men and women and sold by jewelers everywhere.

Movements only are \$12.25 and upward. Complete watches, certain sizes, are \$38.50 to \$150.00. Ask your jeweler about them, also about fitting your present watch case with a Hamilton movement.

Write for "The Timekeeper"

It illustrates and describes the various Hamilton models and is a book well worth reading if you are thinking of buying a fine watch

LANCASTER, PENNSYLVANIA

# The Ten Greatest Inventions of Our Time

We hear much of the great inventions of the past—the telegraph, the sewing machine, the telephone, the reaping machine, photography, Bessemer and open hearth steel, the steam engine and the phonograph. Yet the inventions of our own time are as epoch-making and as dramatic as these.

Perhaps because we have become accustomed to the use of the old machines and discoveries, perhaps because the achievements of latter-day inventors succeed one another so rapidly that we are not given much time to marvel at any one of them, we have not fully realized how stirring and wonderful are the products of modern ingenuity.

Only five years ago the man-carrying aeroplane made its first public flights, only the other day hundreds of passengers on a sinking ship were saved with the aid of wireless telegraphy. At least a dozen inventions as great have been perfected in our own time, and all of them have made a man's work count for more than it ever did before, and have made the world more livable than it ever was.

Why should we not tell the story of our own deeds?

Why should we not pass in review the new industries created by men who are still living, men whose names will go down into history with those of Watt, Morse, McCormick and Howe?

That was the underlying idea of the November Magazine Number of the Scientific American. We knew that the "ten greatest inventions of our time" was a big subject when first we planned the number, but how big it was we never realized until we surveyed the field of modern invention.

Then we saw how astonishing was the progress made in our own day, how much mankind had benefited by the inventions of great modern intellects. We began to appraise inventions, to weigh one against the other, and to determine in our own minds which ten had contributed most to human progress and happiness, which were really great pioneer inventions, and which merely remarkable and valuable improvements on successful past conceptions. There were so many achievements to consider that it was hard to arrive at a definite conclusion.

The upshot of our own thinking has been to leave to our readers the decision.

## What Are the Ten Greatest Inventions of Our Time, and Why?

For the Three best articles on the subject, we offer in the order of merit, Three cash prizes:

First Prize: \$150.00 for the best article

Second Prize: \$100.00 for the second best article

Third Prize: \$50.00 for the third best article

On another page in this issue will be found the rules that will govern the contest.

## Why several grades?

Here are five 4-ounce bottles. Each is filled with a different grade of Gargoyle Mobiloil.

The grades all differ in thickness, or "body."

These oils meet the most severe tests that have ever been exacted from automobile lubricating oils. In sheer lubricating quality they stand alone.

But that, of itself, is not sufficient.

To properly reach the many friction points the oil's "body" must be suited to your feed system.

To make this condition plainer, a homely illustration may be taken from the sewing room:

A fine thread is often too light for the wear required. A heavy thread is often too thick to pass through the eye of the needle.

**Neither meets requirements**  
So it is with automobile lubricating oil.

Quality equal, the heaviest-bodied oil will prove the most durable. But to be of service it must be able to properly pass through your lubricating system.

The conditions to be met are complex. The problem is serious.

**Motors differ.**

### Feed systems differ

Before the oil which best combines durability with ability to meet the feed requirements of your car can be determined, the construction of your motor must be known and carefully considered.

We have undertaken this problem with the thoroughness that has established our

standing in the general lubricating field.

Every year we analyze the motor-construction of each of the season's models. Guided by this analysis and by practical experience we determine the correct grade of Gargoyle Mobiloil for each make of car.

Our findings we list in a lubricating chart, printed in part on this page.

The oil specified for your car in this chart is the scientifically-correct grade for your motor.

The superior efficiency of these oils has been thoroughly proven by practical tests.

If you use oil of lower lubricating quality, or of less-correct "body" than that specified for your car, loss of power, unnecessary friction, and ultimate serious damage must result.

## A word about ourselves

Lubrication with us is both  
a business and a profession.

Throughout the world the lubricating counsel of the Vacuum Oil Company is sought by engineers who must meet the most rigid efficiency standards.

Our clientele includes thousands of manufacturing plants—located in practically every civilized country.

We supply the floating armaments of the world's leading naval powers

We supply the aeroplane  
fleets of the leading military  
powers.

Outside of the home field we supply over seventy foreign automobile manufacturers.

The lubricating chart on this page represents our professional advice.

We suggest that you note down\* the grade specified for your car

In buying Gargoyle Mobil-oil from dealers it is safest to order either a full barrel, half-barrel or a sealed five-gallon or one-gallon can.

Make certain that you see the name and our red Gargoyle on the container.

A booklet, containing our complete lubricating chart, together with points on lubrication, will be mailed you on request.

The various grades, refined and filtered to remove free carbon, are

Gargoyle Mobiloil "A"  
Gargoyle Mobiloil "B"  
Gargoyle Mobiloil "D"  
Gargoyle Mobiloil "E"  
Gargoyle Mobiloil "Arctic"

They are put up in 1 and 5 gallon sealed cans, in half-barrels and barrels. All are branded with the Gargoyle, which is our mark of manufacture. They can be secured from all reliable garages, automobile supply stores, and others who supply lubricants.

## ***A guide to correct Automobile lubrication***

**Explanation:** In the schedule, the letter opposite the car indicates the grade of Gargoyle Mobiloil that should be used. For example, "A" means "Gargoyle Mobiloil A." "Ar" means "Gargoyle Mobiloil Arctic." For all electric vehicles use Gargoyle Mobiloil A. The recommendations cover both pleasure and commercial vehicles unless otherwise noted.

# Mobiloil

*A grade for each type of motor*

# Travel In Comfort

When you travel, be comfortable as well as safe.

The tracks and trains of the Pennsylvania Railroad are built for safety and comfort.

The roadbed is rock-ballasted and evenly graded; and the rails are solid steel. The cars, both Pullmans and coaches, are all-steel, heavy and easy riding. The through express trains have parlor, smoking or club cars with moveable easy chairs, and a la carte dining service that is unexcelled. All sleeping cars are the last word in appointments; the coaches are cheerful, commodious and restful.

Limited trains like the **Broadway Limited** between New York and Chicago, the **24-Hour St. Louis, The Pennsylvania Limited, Congressional Limited, and Manhattan Limited** have Pullman observation cars on the rear with moveable arm-chairs and large windows, as well as an open platform, for viewing the passing scenery. Up-to-date libraries, current periodicals, daily papers, and courteous attendants are features of the Limited train service.

Pennsylvania Railroad service enjoys the reputation of being distinctive-ly high grade, as safe as skill and precaution can make it, and comfortable.

**PENNSYLVANIA RAILROAD**

and this advantage must be accepted. But a few men might have two shoes and even both plows in the year with provision for a power lift, usually a chain and chain-operated shaft.

#### Minimizing the Weight.

Probably the greatest disadvantage of a combined tractor and plow is the fact that the distribution of weight to get the best results in plowing is not the proper distribution when the load is strung out on trailers in the rear. Plowing, however, is the job requiring the greatest power and these other advantages may easily be regarded as of less importance than the securing of the greatest efficiency in plow-  
ing alone.

The great problem of side draft brings out some peculiar combinations. There has been a persistent effort on the part of designers to build a tractor with one drive wheel, thus placing the power directly ahead of the plow. One of these which never reached the market had a drive wheel at the right and rear supporting the weight upon one front wheel at the right hand side and rear wheel at the left. Unfortunately the distribution of weight was not properly calculated and the rig earned the nickname "Tumblebug" before it ever had a chance to plow a row.

A somewhat more successful applicant of the one-wheel idea was made with the tractor wheel in front. A long triangular frame supported at the rear two drive wheels close together, carried three plows which were lifted by power and released by the foot. One advantage of this tractor was its ability to turn a quick corner in plowing. However, it was a plow, a machine pure and simple, making little or no pretense at doing general farm work. For this reason probably it was not a commercial success and was never even advertised to the public.

The next step from the tractors already discussed seems to be the home-made machine. In the *SCIENTIFIC AMERICAN* for February 1st, the picture of a home-made tractor was an eye opener. Many farmers are mounting their stationary engines on trucks made out of binder or mower wheels with gear or chain drive and various other mechanisms. Some motor men substitute an axle in this situation and are advertising motors to the man who wants to build his tractors at home. On the other hand several firms are offering trucks and sets of gears to farmers who wish to build their own machines using the stationary machines they have already installed. It is needless to say that these make-shift outfits have all the economic disadvantages of the small tractor and in addition do not enjoy the advantages of good design and workmanship. It is not difficult to make a tractor that will run but it is so to make one that will meet all the requirements satisfactorily.

#### The Self-propelled Cultivator.

Just now there is an outcropping of a type of machine which seems entirely logical and in fact an advance of the tractor into a separate field from that which we have been discussing. This is the self-propelled light tractor designed merely for cultivating. Several concerns have made such tractors, not claiming them to be sufficiently powerful nor reliable in construction to do heavy plowing. These light machines consist essentially of two high drive wheels with a small steering wheel or trailer to balance the machine. It is claimed that one of these will turn down one corn row into the next and cultivate two rows of corn at one time and is no harder to steer than a team of horses, and much faster.

At present the trend seems to be in the direction of even smaller cultivators, propelled by an engine of three to ten horsepower the driver walking and steering the outfit. Out of all the tractors discussed in a previous article as self-propelled and tillage machines, a motor of this type alone appeared to the writer as more desirable for the American farmer than what we already have. Along these, at least two reasons of the type of tractor being needed. The first is the necessity of a better and more efficient machine.

## A Check Against Waste

Indicator—actual speed

## This Indicator On Your Desk Shows ACTUAL Speed in Your Factory

The Hopkins Electric Tachometer is used by the manufacturer who would know exactly the efficiency of his plant.

It will permanently indicate or temporarily test the speed of machinery in every sort of plant, testing with equal accuracy the speed of a gas or steam engine in a small factory, the mammoth engine in the largest power plant, or the main shaft in the big factory full of small machines. Accuracy is guaranteed.

The precision, the clear output and the apparatus may be instrumental to have the revolutions per minute as to have the most from machines, bring the exact output, or if speed is essential to quality, it will be to be maintained.

### Principle of Operation

The Hopkins Electric Tachometer consists of a small direct-current electric generator and an indicator of the relative motion (instrument) of the indicator shaft and the indicator wheel. The two ends of the shaft are connected by a belt (two wheels) mounted on the shaft. It is well known that when a gear of 20 is connected to a 10, the speed of the gear of 20 is reduced to one-half the speed of the gear of 10. In the same way, the speed of the indicator wheel is reduced to one-half the speed of the generator shaft. It is the speed of the generator shaft that is indicated on the scale of the indicator wheel. The speed of the generator shaft is indicated on the scale of the indicator wheel. The speed of the generator shaft is indicated on the scale of the indicator wheel.

One of these manufacturers advocates his tractor for handling a small turning plow as well as a cultivator. A two-horse line horse power engine of the motor cycle type is used and means are provided to use its power for grinding feed pumping the wheel desired. The outfit is very narrow, only twelve inches wide, thus allowing rows of intertilled crops to be placed close together. It is claimed to do the work of one two-horse plow or two one-horse plows in the latter case cutting two furrows at once. The guiding is accomplished by means of a jointed portion of the left handle which is connected with the axle of the traction wheel. By moving the handle to right or left the axle is moved like that of a bicycle. The plow may be guided and the machine thrown in or out of gear or the speed regulated without letting go of the handles.

The section of the plowshare gives a reasonable amount of traction for the weight of the machine which is 350 pounds. On striking an obstruction the spiked drive wheels slip so that the machine may be thrown out of gear. Only fifty five pounds of weight is lifted by the handle and the obstruction may easily be passed. Two of the machines may be used together so as to convert the outfit into a riding plow. It also has a spring, attachment and a cutter bar for mowing grass to be developed.

Another motor of this type is made with larger wheels to straddle a row. The manufacturers catalogue is full of interest. It being one of the interesting facts that the farmer who owns an automobile could not afford to use his motor on long for either traction or belt work. The stationary engine in the other hand cannot be used easily from place to place and a portable engine frequently requires the use of a horse to pull it about. By making the small engine furnish its own motive power the farmer may have this outfit wherever he wants it in the field or the wood lot in the barn or even in the summer kitchen laundry.

It is an imperial machine working one day for the farmer and the next day for his wife. If the water to be pumped the tractor will go where the water is and pump it. Any make of small cultivator can be attached and the tractor will work in the corn field or in the nursery with equal convenience. The wheels are adjustable so that the space between them may vary from 26 to 42 inches so as to fit any width of corn rows. The left handle is the controlling factor, which turns on and off the clutch so that the tractor will move forward at any speed from 1 to 4 miles an hour.

Two belt pulleys are provided one running at from 700 to 1000 revolutions per minute and the other from ten to forty revolutions per minute. This of course simplifies the problem of supplying the pulleys for different machines. Further than this a special shaft with the universal joint at either end is furnished so that the motor can be direct connected with a generator corn sheller or feed mill. The outfit complete weighs 500 pounds and costs \$295, or about what a real good draft horse will bring. There seems to be no reason why the mechanical difficulties should not be very easily solved in such a machine nor why it should not prove extremely useful if care is taken to perfect it.

### Some Interesting French Machines.

The automobile lawn mower is a familiar sight on large estates and in our parks. Several years ago a leading American manufacturer put out a gasoline mower which was tried out on the farm of the late Senator Dillworth in Iowa. It is, however, did not prove a success. At one of the recent French shows an anti-mower was shown as illustrated in the accompanying photograph. It is not known what success has been achieved in the field. In the background of the same illustration is shown the small cultivator previously referred to as having appeared to be one of the few practical machines designed.

Another new and interesting French model is illustrated with cultivator

## The Problem of the Small Tractor

MODERN conditions demand the use of a big tractor, faster, and more economical unit for farm work. That is why the tractor has come to take the place of the horse. But how big shall we make the tractor—how many horses?

In the United States there are nearly six million farms of less than 150 acres as compared with a million and a half larger than that. Most farmers are men of small business. There is the greatest human interest, then, in a tractor of the size that will fit the smaller farms the farms that are operated with from four to eight horses. The small tractor as understood by the public is one that will fit into the conditions where not over six or eight horses at most are needed to do all the farm work.

The farmer enjoys a great measure of independence. He is regarded as the last defender of individualism. Neither is nor the average person looks kindly upon any evolution that will rob him of his present status. Public opinion is in favor of retaining the small farm and preventing the concentration of the big farm and of capitalist control. The question, then, is of vital human interest as to whether the tractor shall be reduced in size to take the exact place of the horse, or whether, in response to an economic demand, it shall grow as large as the natural limitations will allow. It is the old story—whether or not the instinct of self preservation shall yield to the modern corporate idea of preservation through organization, the division of labor, and the methods possible only when men work together in larger groups.

It is probable that the small tractor pulling two or three plows, will some day be widely adopted. A great many more men could run \$1,000 to \$1,200 to buy a small machine than \$1,000 to \$2,000 to buy a big one. The market for a small tractor once the mechanical and economic difficulties are brought down to an attractive minimum, is enormous. Sales will naturally be easier and the lack of a satisfactory system of agricultural credit may appear to curtail the sales of the larger plow units, even where the farmer and the larger plow judgment would prompt the buying of larger equipment.

The question of how large a tractor can grow in size is currently settled already by inflexible astronomical conditions. The weight that can be constructed in a compact, mobile power plant is limited by the fact that the soil of the fields must bear the burden and still rise over. The railway can increase the size of its engine safely by putting on the locomotive's rails. The soil, however, will support only so given weight without in jury to the physical condition. And again there is an engineering problem, that of moving a heavy mass economically when the soil has been softened by rains. Moreover, communities have had roads and permanent bridges to sustain only what have happened to be the heaviest of tractors that are now available, and in the years to come a fifteen ton tractor will probably be the largest that can prevail.

It is too early to state what will be the final outcome. In the opening of new countries it is not to say that tractors will be built as large as natural limitations will permit. We have seen how instances of the combination of several large tractors along of a single big plow, also built up of units in order to accomplish greater results with the aid of one or more plows. In view of the present great commercial success and the trend of agricultural economies, it is reasonable to assume that a tractor of medium size,

handling four to six plows, will be in greatest demand, and will do the bulk of the work for large farms and farming communities. It is equally evident that in countless cases there will be a field for the small tractor even though cost and operating expenses are proportionally higher than for the larger machine. Finally, many special adaptations of the small tractor will be made to accomplish certain functions where the margin of profit is large enough to overcome a natural increase in complexity and cost.

However, a revolution is taking place in the size and management of the farm. With every census the number of non resident farm owners is increased. Furthermore omitting the suburban truck patch, the farm is growing larger, even in prosperous agricultural States. The larger operation attracts a higher caliber of proprietor and manager, and as in all business, the type of organization prevails that allows the exercise of the highest intelligence and mechanical power as opposed to mere manual labor. It is hard for the average person to see that the individual small proprietor is losing ground. Yet the whole tendency is toward concentration.

There is a deep-rooted and commendable feeling that the solution of our soil fertility problems depends upon the working of the land in small units and the nations of Europe. Small farms, hand methods and intense personal interest in the soil, do tend to conserve this fertility. Yet the large enterprise in which brains and mechanical power play the controlling part, are more apt to phyche the soil. Here in America we are now far too valuable to be used in farming power to till the soil. Men are too costly to be used in holding back evolution. And it is to be hoped that the time is far distant when the struggle for existence in the soil will be decided by the power of the tractor. The conservation of the soil will count at least as much as the uplift of the individual.

After all the soil is not the only resource to be conserved. We need men now in all our industries to take the place of the soil, the mine and the forest, and make them more valuable by the expenditure of increasing skill and labor in factories. The mere production of raw material is not a matter so much for the exercise of skill as for the use of quantity methods, resulting in cheaper costs. The shading of materials for consumption is a matter of skill for which we now pay vast sums annually to foreign countries—bidding the bill with increasing darts upon our natural resources. The labors we release from the soil can be put to legitimate employment in another phase of our civilization.

## The Japanese and the American Navies

IT is a matter of particular importance at the present juncture, in view of the recent crisis, that the people of America should take serious stock of Japanese naval development. The navy of the United States is still incomparably superior to that of Japan, but its superiority is very largely dependent upon ships built during what is known as the "pre-dreadnought" era, and which are therefore in a state of ever increasing obsolescence. The future cannot be guaranteed by a preponderance of units which, whatever their merits when they were built are now wholly outclassed. The Panama Canal while it will add to the mobility of all American fleet increases its responsibilities. The canal has made the navy a shorter route to the Pacific, but it also adds to the dangers that the United States may run in the Pacific. Four years ago M. Saito Kato, one of the best informed of Japanese publicists, wrote in an English naval periodical: "Whether all loved or disapproved Japan's intended Japanese fleet, it will be a misfortune of the Pacific." It will be wise to bear the policy in mind when considering the facts which may be regarded either as the outcome of it or as contributing toward it.

In another page in this issue a comparison of the American and Japanese fleets will be found. The United States has thirteen dreadnoughts built and building to Japan's twelve. The difference in tonnage, such as it is, is slightly in favor of Japan. In gun power, however, the difference is 15 per cent in our favor, although they have one dreadnought less.

There is in these facts no cause for panic. Japan has still, at the outside, only five completed dreadnoughts to the eight of the United States, and, taking into account the more rapid rate of construction in this country, there is no good reason why the pre-portion should be altered. It is, however, perfectly clear that the naval superiority of America over Japan cannot be maintained by laying down one battleship a year. From 1911 onward Japan has laid down or ordered eight dreadnoughts to the four of the United States, and another four battle-cruisers, besides minor craft are provided for in the new Japanese programme. When Admiral Takamune was placing the new programme before the Lower House of the Japanese diet, he declared that it had been prepared by the United States 21 battleships which "a certain Power" might be

able to oppose to it. This was, of course, a direct reference to the United States, since no European power is in a position to risk the dispatch of so many ships to a distant station. It must have become perfectly obvious to statesmen that the United States was in a position of one battleship a year will not suffice to maintain the position of the United States among the naval powers of the world. Between 1901 and 1907, a period of seven years, 25 armored ships were launched for the United States fleet. In the five and a half succeeding years only ten have been launched. No nation can expect to maintain its position in face of such facts as these. With the advent of the dreadnought, coming now to build and to keep up them ships of earlier types, some degree of numbers was to be looked for, but there is no nation that has reduced its rate of construction to such an extent as the United States. At the end of the pre-dreadnought era the United States was easily second to Great Britain. Germany has now surpassed that position, and it is present rate of comparative progress is allowed to continue will not be long before the rise of Japan compels America to take a still lower position in the scale.

## Research on Leprosy

THE work of Prof. Raoul Pietsch of Geneva (Switzerland) on the use of liquid carbon dioxide as a specific for leprosy, has lately been discussed in the newspapers. Wholecure cures are claimed for it in Hawaii. Pietsch's "discovery" is a method of cauterization, not whether more effective than other long used methods along the same lines remains to be seen.

Until recently, leprosy had not been produced in animals for purposes of experimental study, and it is barely four years since the germ was first isolated at the Lindsay Leprosy House. The work of Duval and Courat, in the laboratory of Pathology and Bacteriology at Tulane University (New Orleans) has given a new and sure foundation for future investigation of this disease.

They have established that leprosy cannot be given to any animal by a single injection of the germs. Repeated injections are necessary in order to make the body sensitive. This is doubtless true of human beings, and explains the relative infrequency of leprosy even when persons have lived among lepers for some time.

This is in agreement with a long line of new theories regarding the *modus operandi* of infection. Typhoid germs take two weeks to make the body sensitive enough to give the disease a start. During this period of incubation millions of bacteria are being killed in the course of forty-eight hours, but the disease is not produced until the body reacts. In leprosy it would seem that the germs are repeatedly killed off by the body.

Duval says that "to produce the disease experimentally, it seems necessary to give the animal repeated injections of large numbers of leprosy bacilli at given intervals for a period of months." His research shows that the injection of four million and later of four billion bacilli were given before the disease "took." Even after the first injection of four million bacilli and for nearly two weeks after the injection of the culture containing four billion "there was no evidence of either localized or general infection." The animal first infected with leprosy was a monkey (*Macaca mulatta*), the initial injection being given October, 1910. It did not until the following March that he was recognized as afflicted with a disease having all the clinical characteristics of "human leprosy," and death did not ensue until December.

## Counting the Waves of the Sea

MANY oceanologists believe that certain types of microseisms, those of a period of say from four to seven seconds, are due to the pounding of sea waves on the seashore. In order to test this idea more fully the International Oceanological Association, in 1909, voted 1,000 marks to be used by its committee on microseisms in constructing an instrument for registering ocean waves. This "undergraph" is called, has now been built, and is described by the *Journal of the Royal Meteorological Society of America*. The original undergraph was set up in 1913 at Tynemouth, England, on the North Sea, but a location more exposed to the full force of ocean waves has now been found at Chelveston, outside the harbor of Hafford, N. E. of London. The pipe extends into the sea with its mouth below the lowest stage of the tide or wave trough. The other end of the pipe is on land, and is so arranged that, with each incoming wave, the water rises, compresses the air above it, and gives off Hafford, N. E. of London, an electrical recording apparatus. The waves of the sea are thus registered, but there is not, as yet, any arrangement for registering their amplitude. The recording apparatus will be installed in a lighthouse, and the recorded results will be compared with those of a Roach seismograph at Ostend.

Föttinger transformer of ten thousand horse-power for ship propulsion installed on the Vulcan-Werke's testing floor with steam turbine and Föttinger brake. The insert shows the rotor of a ten thousand horse-power hydraulic transformer for marine service.

## Tests on a 10,000 Horse-power Föttinger Transformer

### Hydraulic Gear for Marine Turbines

By Dr. Alfred Gradenwitz

It will be remembered that the Föttinger transformer is a hydraulic transmission gear intended to transmit loads up to the highest figures from a motor shaft to another shaft coaxial with the former. It can be designed for an equal number of turns of both shafts or for transformation into lower or higher speeds, for the same or an opposite direction of rotation, and it thus constitutes a reversing gear which allows the driven shaft to be reversed while the driving shaft continues working as before. The principle of transmission can be briefly described as follows: A rotor mounted on the primary shaft is designed as a high grade centrifugal pump, lifting water which in the water wheels mounted on the second shaft, works under similar conditions as in hydraulic turbines. By a skillful combination of these wheels, Dr. Föttinger has produced a compact gearing of remarkable safety in operation and satisfactory life, in connection with which any losses due to hydrodynamic transmission are reduced to a minimum.

In view of these special features of the Föttinger transformer and the advantages it shares with all hydraulic machines, it is especially adapted to serve as an intermediate gearing on board ship, between the steam turbine and the propeller. It is well known that the economical speed for marine steam turbines is much higher than that desirable for the propellers driven by the turbines. The interposition of the transformer between the tur-

bines and the propellers enables both to be driven at the speed which gives for each the highest economy.

Interesting tests were recently made on the testing floor of the Hamburg turbine factory of the Vulcan-Werke, which were intended to demonstrate the suitability of the Föttinger transformer for the very largest outputs. A reversible transformer of 7,500 horse-power normal output, intended for the propulsion of a large transatlantic steamer of one of the big German shipping companies, was submitted to a continuous test

of 14 days' duration, at high loads (5,000 to 10,000 horse-power). The arrangement of these tests was as follows:

A steam turbine of the Curtis-A. E. G. Vulcan system was installed on the testing floor, the primary of the transformer being coupled to the turbine. The secondary energy was braked by a large hydrodynamic Föttinger brake designed for a maximum output of 10,000 horse-power, the propeller thrust being replaced by an hydraulic axial thrust so that the trans-

former was actually operated under the same conditions as it will eventually be in the vessel. Between the driving turbine and the transformer on one hand and the transformer and the brake on the other were inserted torsion gauges for determining the primary output and checking the secondary output as indicated by the brake. The normal output of the transformer corresponds to 800 revolutions per minute of the primary shaft and 100 revolutions per minute of the secondary shaft.

These tests have shown the efficiency of the transformer to be up to 90 per cent. The transformer was found to work with absolute smoothness, without any vibration or noise, reversal being effected with astounding rapidity and safety. The speed of rotation of the turbine, even during reversals, was kept permanently within given limits by means of a centrifugal governor. It may be as well in this connection to state that the

General view of a ten thousand horse-power Föttinger transformer for ship propulsion.

(Continued on page 44.)

Graphic comparison of Japanese and American dreadnoughts and their armaments.

## The Japanese and American Navies Compared

### How Japan is Outstripping America

By Percival Hisslam

AT this moment the principal Japanese warships in service are the battleships "Ratsuma" and "Aki" and "Kawachi" and "Settsu." The first two, though not dreadnoughts in the strict sense of the word, are certainly entitled to rank as such. The "Settsu" displaces 10,550 tons and carries four 12-inch, twelve 10-inch, and twelve 4.7-inch guns, while the "Aki" displaces 10,900 tons and has eight 6-inch in place of the 4.7-inch weapons. The other two ships are typical dreadnoughts, displacing 20,800 tons and carrying twelve 12-inch guns apiece. In addition to these ships the battle-cruiser "Kongo" has just completed her trials after construction in England by the Vickers firm. She is a ship of 27,000 tons, with a designed speed of 27 knots, and is armed with eight 14-inch and sixteen 6-inch guns. The significance of the fact that Japan has a ship with 14-inch guns completed several months before the New York and "Texas" are due to be completed, ought not to be overlooked.

Besides these ships, Japan has actually under construction the battle-cruisers "Hama" and "Hiei" and "Kirishima," and the battleship "Fuso." The first three are sister ships to the "Kongo," and the "Fuso," although her details have not been officially published, is understood to have a displacement of 20,000 tons and to carry an armament of ten 12-inch guns. These four ships are all building in Japan—a fact which itself speaks volumes for the progress made by that nation in recent years. Not one of the battleships or armored cruisers that took part in the campaign against Russia less than ten years ago was native-built, but since then Japanese yards have completed four battleships averaging 20,000 tons, and four armored cruisers, of which two displace 13,700 tons and two 14,000. It is true that a good deal of the material used in the construction of these ships was imported, but the percentage of imported material has diminished considerably. For the battleship "Ratsuma," completed in 1910, 61 per cent of the material was imported, but for the "Kawachi," completed in 1913, only 50 per cent. This means that Japan is rapidly becoming a self-contained nation so far as naval construction is concerned.

During the past few weeks three more battleships have been ordered—all in Japan. One is to be built at Yokohama (dockyard), one by the Mitsubishi Company (Nagasaki), and one by the Kawasaki Dock Company (Kobe). In building the new programme before the Lower House, Admiral Mikasa, "Vice Minister of Marine," stated that she original scheme prepared by the Navy Department provided for the construction of 1 battleship, 3 battle-cruisers, 10 armored-cruisers and 20 destroyers. This, however, would have cost \$270-

000,000, and the finances of the country were not in a position to stand such an outlay, and it had therefore been decided to reduce the programme to 8 battleships, 4 battle-cruisers, 8 semi-cruisers and 40 destroyers. It was definitely stated that this did not include the ships at present under construction, and that the total cost was estimated at \$100,300,000. As a preliminary step toward the execution of this scheme it had been decided to lay down three battleships at once, and these are the sister ships to the "Fuso," referred to at the beginning of this paragraph.

Looking as dreadnoughts the battleships "Ratsuma" and "Aki," the present dreadnought strength of the Japanese may be five ships completed and seven under construction or on order. The corresponding totals for the United States are eight ships completed and five on order, giving a numerical superiority of 13 to 12 in favor of the United States. This is admittedly backed up by a great advantage in "pre-dreadnought" ships, but these are quickly dropping out of the scale of naval power, and no nation that looks a yard in front of its own nose will be deluded into placing more reliance upon them than they are really worth. The future, so far as the eye can see it with any certainty, is with dreadnoughts, and of dreadnoughts the United States has 13 ships built and building to Japan's 12.

Examining these totals more closely, the position is not so favorable as even this niggardly margin would indicate. The following table gives the tonnage of the vessels concerned:

UNITED STATES.		JAPAN	
Ships.	Tons.	Ships.	Tons.
2 Michigan	23,000	2 Ratsumas	20,150
3 Delawareans	40,000	3 Kawachis	41,000
2 Floridas	48,000	4 Kongos	110,000
2 Wyominges	22,000	4 Fusos	120,000
2 New Yorks	34,000		
2 Nevadas	35,000		
1 Pennsylvania	21,000		
13 Dreadnoughts	307,650	12 Dreadnoughts	310,700

So far as tonnage is concerned—and tonnage is usually reckoned as expressing fighting power in one form or another—the twelve Japanese dreadnoughts built and building are therefore superior to the thirteen of the United States. In comparing gun-power the figures are naturally more complicated, but if the statement, generally accepted, is right which credits the Japanese "Fuso" class with ten 15-inch guns, the

comparison as regards the dreadnoughts tabulated above is as follows:

Caliber	United States	Japan
15-inch	22	40
14-inch	172	120
12-inch	21	21
10-inch	184	184
8-inch	186	186
6-inch	208	208
4.7-inch	208	208

Among the Japanese guns, the projectile of the 15-inch weighs 1,000 pounds, of the 14-inch 1,400 pounds of the 12-inch, 800 pounds, of the 10-inch, 500 pounds of the 8-inch, 100 pounds, and of the 4.7-inch, 45 pounds. Measuring gun power on the basis of one round fired from each gun, it will be found that the Japanese dreadnoughts are superior to the American in 170,000 pounds of metal to 154,880 pounds. Measured by the usual scale of dreadnought comparisons, this indicates a Japanese superiority in gun power of 15 per cent, in spite of an inferiority, small though it be, of 12 ships to 11.

### What is a Dendrologist?

DENDROLOGIST is the name applied to one who is engaged in the study of tree botany or dendrology, which is derived from the Greek words *dendron*, tree and *logos*, discourse; a tree tree on trees. Dendrology may thus be defined as a branch of botany that treats of trees, which properly includes taxonomy, morphology, anatomy, physiology and ecology of tree species. While dendrology is a division of botany, it is far more specialized and includes a knowledge of plant life, which is seldom considered to be a part of systematic botany (the who knows botany in a general way is not necessarily a forester, but the dendrologist who has specialized in all phases of the scientific knowledge of trees, including a study of the factors which influence the life and growth of trees in their natural or adopted habitat, possesses the requisite training of a forester. A thorough knowledge of the life history of trees forms the basis for all silvicultural operations which are naturally included within the sphere of dendrological studies. The word dendrologist originated in England in the seventeenth century, and was probably used first by Evelyn in order to designate definitely the expert engaged in the study of tree botany and dendrology in order to designate the work itself.

## Mining the Air with Balloon Torpedoes

By Major E. Bauman-Phillips

**T**HE delivery of the "First Wilbur Wright Memorial Lecture" at the Royal United Service Institution by Mr. Horace Darwin, before the members and guests of the Aeronautical Society, rendered the lecture and the address that it was the great American investigator, indefatigable pioneer, and skilled constructor and aviator, who, in conjunction with his brother Orville, first took flying out of the dreams of fancy and made it a living fact. It was inevitable that their personal and the progress of the air should take its immediate stimulation for purposes of war. We must face the possibility of fresh methods of warfare superadded to those with which we are already acquainted. How will these affect the attack of fortified places, more especially sea ports and naval war harbors?

In considering the problem of injuring coast defenses, and arsenals or storehouses containing material for refitting war-vessels, the first question which occurs to the mind is the possibility of damage by bomb harassment, and the second, except to which the attacking ships can approach in order to use their guns with effect. The second is the chance that may exist of inflicting blows on such nerve-centers of the defense as, on account of their affecting the control of the defender's artillery or the supply of ammunition, may be important to partially, if possible, as a preliminary to a more general attack.

We may infer, from the experiences of the Russo-Japanese war and from the more recent sinking of merchant vessels in Japanese harbor—the aftermath of submarine during the Russo-Italian and Russo-Balkan wars—that until the sweepers and crows of an attacking fleet have thoroughly gone over the mine-field which will cover every coastal defense of any importance, the large ships will have to move with extreme caution, and at great risk if they want to get within range of the enemy's defenses. The development of the steerable automobile torpedo with its long range, is another question to be considered by the hostile fleet, for the local torpedo flotilla, and the submarines by day and destroyers by night, will be constantly on the lookout for the enemy's mine-layers. Even in the Russo-Japanese war the long range torpedo had not to be very seriously reckoned with, but now it has become a potent factor.

This being so, and since an attacking fleet will have, during the initial operation at any rate, to keep at a safe distance from properly equipped harbor defenses, there will be every reason for commanders to use the air as a means of first reconnoitering, and secondly endeavoring to cripple the defenses on shore by the destruction of nerve-centers, the destruction of arsenals, setting fire to store-houses and oil tanks, and creating a depressing moral effect on the garrison.

It has been suggested that fortified places might be protected by a system of aerial mines in captive balloons to prevent airplanes from getting vertically over the defended area, these being equipped with electricity from below, or in consequence of being fouled by the attacking dirigible in its endeavor to place itself in the required position for dropping explosives.

This is the old, and inefficient, method of passive defense. The range of modern aerial shipboard artillery is far greater than the height attainable by a dirigible, but supposing 6,000 to 8,000 feet to be a safe altitude from artillery, the object of the "mine" (captive balloon) would be to cause danger at a still higher altitude. During the last war balloons were used for every 1,000 feet, it will be seen that 6,000 feet of cable would weigh 420 pounds, so that the balloon would have to lift this plus the weight of envelope, car and explosives. The weight of a captive balloon of 10,000 cubic feet capacity capable of about 250 pounds, and its lift capacity, would be 10,000 minus 420 pounds, or with coal gas, 775 pounds, and coal gas would probably be used for "mine" balloons on account of the great expense of hydrogen. The weight to be lifted would therefore be 420 + 250 = 670 pounds. The altitude of the balloon, at a height of 6,000 feet above sea-level, the lifting power of the hydrogen would be reduced to 840 pounds, because the volume of air which it displaces, although the same at that altitude, is lighter and the lifting power of the gas is the difference between its own weight and that of the equal volume of the surrounding air. Therefore the captive balloon could not carry its own weight and its cable to the height of 6,000 feet, without taking into consideration the occasional increase in weight from moisture deposited by rain or dew in the envelope, which might amount to another 100 pounds.

In a fog or at night an enemy's airplane, moving without searchlights for concealment, might run foul of one of the captive "mine-balloons" in endeavoring to get vertically above the defended area, but by daylight and in clear weather, and if it were detected by the presence of mobile aircraft guarding the defenses, it

could fly round the area at a safe distance and destroy the "mine" by the use of its machine-gun, or by a succession of the flame type, worked by compressed air; the explosion carried by the mine would not be complicated by the fire of the airplane, fall upon and damage the buildings, etc., which they were intended to guard.

A high wind, or a sudden storm gust, might cause the same effect, and lightning might explode the balloon, and cause the descent of the explosives with similar results, although the balloon could be connected electrically with the earth by way of protection.

If the "mine-balloons" were stationed close enough to one another to form a defensive enclosure or network, the wind would cause the cables for one another and get entangled. It does not take much wind to cause the cable of a captive balloon to assume a considerable angle with the vertical, and the farther the balloon is carried down wind, the more the cable slopes from the balloon to the ground. In a strong wind, unless the surprise "lift" of the gas is very great, the balloon is brought close to the ground and cannot rise to any height. The greater the "lift," the higher it will rise, but to obtain this, the size of the balloon must be large in proportion to the weight it has to raise, and the surface it presents to the wind and consequent difficulty in riding are increased accordingly.

On the whole, it would be more profitable to trust to the airplane-destroying artillery armament of a fortress for local defense and expend the funds which would be required to equip balloons for one another, on strengthening the mobile aerial equipment, in other words, meet the menace of aircraft with still better aircraft, which could either deal with the enemy's dirigibles before they reached the guarded area, or, when met, pursue and attack them by machine-gun fire, if they were very nearby. The superiority of the possession of a superiority of aerial cruisers would do more to check reconnaissance and attack than the most elaborate preparations for passive defense.

## The Langley Aerodynamical Laboratory

By Carl Hays Bateman

**T**HE Langley Aerodynamical Laboratory is a fitting and lively tribute to him who contributed so much toward the solution of the problem of mechanical flight.

The laboratory is under the Smithsonian Institution, and its object is to study the problems in aerodynamics, which with such rapid extension, it has become necessary to increase the safety and effectiveness of aerial locomotion for the purpose of commerce, national defense, and the welfare of man.

The laboratory was authorized by the Board of Regents at a meeting on May 14, 1915, called especially for the report of a committee previously appointed for the consideration of this matter.

The laboratory is to be under regulations to be established, and fees to be fixed by the chairman of the General Committee, with the approval of the Executive Committee of the Board of Regents. It may exercise its functions for the military and civil departments of the Government, as well as for any individual, firm, association, or corporation in the United States, provided such department, individual, firm, association, or corporation shall defray all the expenses accruing from any such services rendered by the exercise of the functions of the laboratory. Bulletins and other publications for public distribution, containing such information as may be valuable to the Government or the public, shall be issued from time to time. These publications will include an annual report which will cover the work of the laboratory and the researches of the general and sub-committees.

It was deemed advisable to have the work divided up into several experiments, and members of the general committee were designated as chairmen of several sub-committees, the exact names, functions and personnel of which have not yet been determined.

The General Committee, it is understood, will take charge in an advisory manner of all aeronautical research, consultation and administration, in which the Government may become interested or foster; in this way, it will be a general advisory committee on aeronautics. Its functions will be numerous and its scope national.

In the Smithsonian Building has been made available by the secretary, Dr. Alfred Sahn has taken up the office work of recorder, and is planning the publication of a hand-book intended to show the scope and functions of the committee in general, and the laboratory in particular.

The project has been sanctioned by the Board of Regents through an appropriation of \$100,000 for the present year, and \$50,000 annually for five successive years. A valuable addition to the office of the committee is the library relating to aeronautics, already located in the Smithsonian Building. For several years Mr. Fred Brockett, assistant librarian of the Institution, has been collecting publications, especially periodicals, relating to

aeronautics, and these have been added to the volumes and pamphlets brought together by his secretary, making a very large collection. The library is open to all, and it is not too large a statement that the Government is now, although indirectly, to promote aviation and the study of aeronautics after, say, years of activity, and that the branch of it to carry on the work is that whose secretary previously undertook the now historical and somewhat arduous task of securing the unfortunate accident, and receiving much public ridicule, were terminated by the Government, which thereby lost an opportunity for international leadership in aeronautics. It is hoped that now the United States will pursue what investigations and experiments are undertaken by the committee, in the Langley laboratory or elsewhere, and in no event relax its interest or neglect opportunities for the national development of aeronautics.

## "The Mysterious Problem"

By Clarence T. Hubbard

**T**HE following combination of two old principles makes a pleasing conjuring experiment for parlor presentation. It is very simple in operation, requires no skill to speak of, yet with appropriate "patter" it makes an exceedingly clever effect. The method for most satisfactory is as follows: The performer displays a large sheet of white paper, calling attention to the fact that it contains no writing or marking of any kind. This is suspended from a frame or roded against an easel in full view of the position. Then the exhibitor addresses the audience and requests them to think of a number. This being done, they are asked to multiply the number thought of by 2. The next step in the process is to add 8 and to then divide the result thus obtained by 3. Next, direct them to subtract the number originally thought of and to add 4 to the final result. The conjurer then applies a match to the paper, which is seen to burn up with the exception of a strip that resembles the figure 7 very distinctly. Seven proves to be the answer to everybody's problem regardless of the fact that each person thought of a different number to begin with. To obtain the effect with the paper the reader must add a few drops of nitric acid to a sufficient quantity of asbestos paint and with a brush outline the figure on the paper and allow it to dry. The figure of one must be painted to giving the exhibition. Seven will always be the answer if the above formula is employed. A little talk relative to the peculiar properties of the figure seven would add to the amusement of the trick. Try it.

## The Current Supplement

**I**n this week's issue of our SUPPLEMENT Sidney Low addresses the question "Is Our Civilization Dying?"

It is difficult to go beyond the causes of the decline of great empires. "Are they physiological?" Or was moral corruption the principal cause? These and many other questions Mr. Low seeks to answer—A tragic balloon accident, presenting very unusual features, recently occurred near Paris. An illustrated description of the facts known is reproduced from French sources—Chester I. Lucas describes the manufacture of steel type, such as is used, for example, for stamping metal articles—Prof. Robert endeavors to page the length of geological epochs on the basis of radioactive phenomena—Prof. Charles L. Davis gives a comprehensive review of the present situation as regards occurrence and extraction of uranium and radium ores in this country and abroad—S. V. Hayward, in an article entitled "Glimpses of the Moon," discusses some of the most interesting problems which the moon presents to all heavenly bodies—He wants to us: Are the volcanoes on the moon still active? Is there vegetation on our satellite? These are questions which some astronomers are disposed to answer with yes—D. A. Lyon writes on the use of the electric furnace in the production of iron from the ore in an article entitled "Early Plans presented to the modern some remarkable vagaries of nature in the fish world—The article by A. J. Lotka on "Evolution From the Standpoint of Physics" is concluded in this issue.

## What Is the Minimum Lung Capacity?

**U**NDOING what is known as the "pneumothorax" experiment, Bernard and his group showed in France that the minimum lung capacity which is compatible with life may be estimated at the sixth of the normal capacity. J. Courmand, in his experiments which he has been carrying on for a number of years, studies similar conditions in the case of animals. He has shown that the portions of the lungs of animals such as rabbits, dogs, and cats that these animals are able to live for several months after the ablation of three quarters of their lungs. In addition to this, he states that the minimum lung capacity of the human subject is about one eighth of the normal capacity. He also states that the lungs of the human subject are able to live for several months after the ablation of three quarters of their lungs. In addition to this, he states that the minimum lung capacity of the human subject is about one eighth of the normal capacity. He also states that the lungs of the human subject are able to live for several months after the ablation of three quarters of their lungs.

# Bacteriology and Your Health

## Serums and Vaccines in the Diagnosis, Treatment and Prevention of Disease

By Dr Charles

F. Bolduan

It has long been known that certain infectious diseases occur naturally only among some of the lower animals and do not attack man, while, conversely others appear to attack only man. Moreover we are all familiar with the fact that persons who have once had, say measles, or scarlet fever, or small pox are thereafter safe from a second attack, or as it is usually expressed are "immune." Since little was known as to the real nature of the infectious diseases until about thirty years ago, it is easy to see how the discoveries of bacteriology in the eighties opened up a wonderful field for the medical investigator, and although most of the fundamental researches concerning the nature of immunity against infectious diseases date back hardly more than fifteen to twenty years, much light has already been shed on many obscure problems of medicine and the promise of further substantial benefits to mankind is held out. True the work of Jenner in the end of the eighteenth century taught us the value of vaccination against small pox, and Pasteur in 1881 demonstrated his method of successfully protecting animals against anthrax by injecting them with living weakened anthrax bacilli. Neither of these discoveries however important as they were, gave any real insight into the nature of immunity. The subject was really illuminated when Behring, in 1890, announced his discovery of diphtheria antitoxin.

But let us go back, for a moment to the time of Pasteur, say to the late forties of the last century. It was well known that individuals who had had one attack of a particular disease were thereafter practically safe from a second attack. In other words, they were immune. The fact of immunity is well illustrated in scarlet fever, measles, small pox, yellow fever. Often it lasts throughout the lifetime of the individual though there are exceptions. In studying this required immunity, Pasteur conceived the idea of artificially producing an attack of a given infection in order to protect the individual against another attack. He realized that it would be necessary so to control tests that the original attack should run a very mild course and not endanger the life of the individual. After considerable experimentation he found that this could be accomplished by artificially weakening the bacteria with which the original attack was produced. Subsequently, Salmon and Smith, two American scientists, showed that it was not necessary to produce even a mild attack of the disease by the injection of living bacteria, but that the injection of dead bacteria would produce an immunity against that particular bacterial infection. This form of immunity, whether caused by a previous natural attack of the disease or artificially by the inoculation of bacteria is always *active* in the sense that is, the protection extends only to the particular disease which has previously occurred or whose germs have previously been injected. An attack of scarlet fever protects only against scarlet fever but not against measles, for example, an individual with typhoid bacilli protects him only against typhoid fever but not against diphtheria or plague or cholera.

When Behring announced his discovery of diphtheria antitoxin, a host of investigators were at once taken up the study of the blood serum as affected by bacterial injections. At their head was Paul Ehrlich and it is largely to his extraordinary genius that we owe our present knowledge of this intricate subject. As a result of these investigations it was found that in response to the invasion by pathogenic bacteria the body manufactures certain specific substances designed to destroy the invaders or to neutralize

In order to obtain the antitoxin of the inoculated animal a sterile, hollow needle is inserted into the jugular vein. About six or seven quarts of blood are thus collected. The serum is drawn off and constitutes the antitoxin used by the physician.

Much interest has been aroused during the past few years in studies in serum treatment, and much has been written about the marvelous success achieved by our army surgeons in preventing typhoid fever during the maneuvers by the use of typhoid vaccines. More recently the newspapers have been filled with accounts of Friedmann's alleged cure for tuberculosis by means of living tubercle bacilli. In order to give our readers an intelligent idea of the principles underlying these modern therapeutic methods, we have asked Dr. Charles F. Bolduan, a well-known authority in this field, to prepare for us a clear account of this highly technical subject. For years on the scientific staff of the bacteriological research laboratory of the New York city health department, Dr. Bolduan has become widely known by numerous papers in scientific journals, and as the author of several text books dealing with the subject here discussed.—FARMER.

Chart showing the result of anti-toxin treatment in diphtheria.

The large circle represents the death rate from diphtheria per 100,000 of population in nineteen large cities of the world. Note the rapid fall in the year 1905, following the introduction of antitoxin treatment in that year.

their poisonous products. These antagonistic substances are spoken of as antibodies. The important antibodies thus far known are (1) antitoxins, (2) bactericidins, (3) agglutinins, (4) opsonins, (5) precipitins, and (6) antiferments.

When an animal is injected with gradually increas-

ing doses of diphtheria poison, it withstands doses of the poison after a time which would suffice to kill hundreds of animals not so treated. This was done by Behring, in 1890, who found that the blood serum of the treated animal contained something which neutralized the diphtheria poison and rendered it harmless.

What could be more natural than to see whether this blood serum could be used to treat other animals previously injected with diphtheria poison? Behring found that the serum thus used was able to save the animals from death. The action of the substance in the serum which counteracted the effect of the poison proved to be exactly like that of an alkali on an acid, i. e., it neutralized the poison. It was therefore called an antitoxin. The antitoxin serum does not differ in appearance from that of a normal, untreated animal, and even when tested chemically, but little difference can be discovered between the two. In order, therefore, to recognize the presence of this antitoxin in the serum, and equally in order to measure its amount, we must test it in animals, and see how small a quantity of antitoxin serum will save an animal after injection with a certain amount of diphtheria poison. It may interest the reader to know that sometimes as little as 1/5000 cubic centimeter suffices to save from death a guinea pig which has received ten fatal doses of diphtheria poison.

In the manufacture of diphtheria antitoxin sheep were first used as the source of the serum, but at the present time horses are almost entirely employed. They are easily managed, produce high grade antitoxin serum, and yield enormous quantities of serum if properly bled. The animals are injected subcutaneously, receiving from 10 to 20 cubic centimeters of diphtheria poison sufficient to kill about five hundred guinea pigs. Using gradually larger and still larger doses, the injections of poison are repeated weekly or oftener for about three months, at which time the horses will be found to have manufactured considerable antitoxin. In order to obtain the antitoxin, the animal is bled by inserting a sterile, hollow needle into the jugular vein, about six or seven quarts of blood being collected at one bleeding. The veins, the stoppers, as indeed all the utensils used for holding the serum, must be absolutely sterile, and every possible precaution must be taken to avoid contamination of the serum. The blood having been carefully collected in sterile flasks is allowed to clot, which causes the clear, straw-colored serum to separate. This serum is drawn off and constitutes the antitoxin as it is used by physicians.

The success attending the use of diphtheria antitoxin is now so well recognized that I need not go into that phase of the subject. Suffice it to say that prior to the introduction of antitoxin the mortality from diphtheria was about five times what it now is. This is well shown in the chart on this page.

Unfortunately it has been found impossible, except in a few instances, to produce antitoxins because very few animals secrete toxins like the diphtheria bacillus. Careful study of the blood serum has shown, however, that even though no antitoxin is produced, the injection of bacteria in other forms causes the formation, by the injected animal body, of substances which kill and dissolve the invading bacteria. Thus, if an animal is injected with typhoid bacilli, the serum will kill enormous numbers of typhoid bacilli after a time, even in very small doses, but against cholera bacilli or against any other bacteria so destructive effect is absent that of normal serum from an untreated animal. When the action of the

serum on the bacteria is studied under the microscope it is seen that the bacteria are actively dissolved. Hence such a serum is spoken of as a bacteriolytic, which means bacteria-dissolving. Since the bacteria are killed by this action, we also speak of the serum as being bacteriodes, which means bacteria-killing.

It has been found that this action of the serum may be developed against other cells than bacteria. When red blood cells are used, the serum acquires dissolving properties for these, and here again, the action is strictly specific, so that when blood cells from a chicken are injected into another animal, the serum of the injected animal acquires increased solvent powers only for chicken blood cells, but not for blood cells of other animals.

Investigation showed that the mode of action of these dissolving sera was somewhat complex and required the joint action of two different constituents. One of the constituents decomposes very easily, so that a serum which is a good several days may be found to have entirely lost its solvent power. This unstable constituent, however, is not peculiar to the serum of the treated animal, but is found in all fresh sera, even in those from normal, uninfected animals. Hence it is possible to restore the solvent power to old, specific dissolving sera by the addition of a little fresh serum from a normal animal. This unstable constituent is spoken of as "complement." When using specific bacteriolytic sera therapeutically, we do not attempt to secure freshly-drawn serum, but rely on the complement present in the blood of every individual to supply the unstable constituent. For reasons largely still unknown, the use of many of these specific bacteriolytic sera for the cure of infectious diseases has been quite unsuccessful, and many diseases still remain to be overcome. In some instances the fault seems to lie, not with the serum, but with the mode of its application. Thus, in the case of the serum for epidemic cerebro-spinal meningitis, the results first obtained were most discouraging, at that time the serum was given by means of subcutaneous injections. For some years past, however, the results have been uniformly good, the mortality being less than half that in cases treated without the serum. The serum is the same as before, but now it is always introduced directly into the spinal canal, where it can directly attack the invading bacteria.

The researches of Metchnikoff showed that the white blood cells, or leucocytes as they are called, lay hold of and digest invading bacteria, and thus constitute an important means of defense against bacterial invasion. Subsequently, Sir Kenneth Wright, a distinguished English physician, showed that certain substances present in the blood serum have the power of increasing the appetite, as it were, of the leucocytes, and, furthermore, that the amount of these substances can be increased by properly administered injections of the same bacteria it was desired to destroy. These substances in the blood serum he called *opsonins*. Wright devised an ingenious technique for measuring the opsonic power of the serum, using fresh human leucocytes, a suspension of the test bacteria, and serum from the patient. After allowing them to remain in contact for a given time he prepared microscope preparations and noted the result. He compared this with a similar preparation made from the same leucocytes, the same bacterial suspension, but with serum from a normal individual instead of from the patient. He showed that before commencing treatment the patient's opsonic power was low, as evidenced by the small proportion of bacteria taken up by the leucocytes in comparison to those in the specimens with serum from the normal individual. With successful treatment with bacterial vaccines (see below), he caused the opsonic power to rise, as shown by the increasing proportion of bacteria taken up by the leucocytes, and with the aid of the injection he aimed the opsonic

Collecting vaccine from a calf.

The calves which are used in the preparation of the virus are first washed the long hair is clipped, and the skin is cleaned with an antiseptic solution, after which the surface to be operated upon is shaved. The animals are then conveyed to the operating room, where they are vaccinated with tested virus under conditions similar to those existing in the operating rooms of modern hospitals, after which they are transferred to the propagating stable and kept as calves as possible. In about six days the virus is removed as shown in the picture, and ground up into the pulp used to vaccinate human beings against small-pox.

power of the patient's serum to be even greater than that of the normal individual. The measurements are always relative, the ratio between the average number of cells in the two sets of preparations constituting the opsonic index. This will be clear by studying the annexed diagrams.

But this does not yet exhaust the list of antibodies produced by the animal body in response to injections of bacteria. When the serum of an animal which has been repeatedly injected with bacteria is brought into contact with some of these bacteria, careful observation under the microscope reveals an interesting series of changes. Thus, if typhoid bacilli are mixed with the serum of a rabbit which has previously been treated with injections of typhoid bacilli, or if the bacilli are mixed with serum from a patient suffering from typhoid fever one notices first that the typhoid bacilli become sluggish in their movements. This is followed by the gradual collection of the bacilli into clumps, and, finally, after a short time, in place of countless bacilli moving quickly through the field, one sees merely several groups of absolutely immobile bacilli. This phenomenon is spoken of as agglutination, and the substance in the serum which brings it about as agglutinin. Like the bacteriolytic, the antitoxin, and the opsonin, the agglutinin are strictly specific, i. e., serum from an animal previously injected with typhoid bacilli will clump only typhoid bacilli, one from an animal injected with cholera bacilli will clump only cholera bacilli, etc. The simplicity of this reaction, as well as its specificity, has made it one of the adjuncts in the diagnosis of typhoid fever and other infections. The microscopic appearance of the bacilli before and after clumping is shown in the annexed drawings.

It must not be thought that the list of substances above enumerated is in all complete, or, what is more, that invasion of the body by bacteria produces changes only in the blood. Not only are still other antibodies produced in the skin, but investigation has shown that other tissues of the animal body likewise undergo subtle changes in response to bacterial invasion. This fact is made use of in the diagnosis of tuberculous infection by means of the skin test. A small quantity of tuberculin (extract of tubercle bacilli) rubbed into a tiny abrasion in the skin of a tuberculous individual causes a typical inflammatory reaction at the point of application, while in uninfected individuals no such reaction results. The test is sometimes performed by dropping a weak solution of tuberculin into the eyes, causing a marked conjunctival (pink) eye in tuberculous individuals.

Because of the success attending the use of the antibacterial sera previously discussed, attention has been turned to treatment of bacterial infections by means of active immunization. This consists simply in injecting the patient with small doses of dead bacteria, thus causing the production, on his part, of the various antibodies already described, and so bringing about a condition of immunity. The injected dead bacteria are spoken of as a "bacterial vaccine." This method may be dated to the researches of Pasteur concerning protective inoculation of animals against anthrax. It will be remembered that Salmon and Smith showed that even dead bacteria could be used for protective inoculation. The protective inoculations against typhoid fever, as practiced by the United States Army, consist of dead typhoid bacilli. Largely through the efforts of Wright such inoculations are also extensively used to cure an infection already in progress, and in a limited number of infections, strikingly successful results have been obtained. In a number of other infections, e. g., typhoid fever, the bacterial vaccines have been remarkably successful in preventing the disease, but practically without value in the treatment of cases already established. (Continued on page 562.)

## Shape and Sound in Whistles

By Gustav Michaelson, Costa Rica State College.

IF it is considered that whistles are among the oldest musical instruments the fact that very little is still known about the origin of the sound which they emit seems strange. One and the same explanation was found not long ago in nearly all elementary text books on acoustics. Condensations are produced, we were told, at regular intervals by the collision of air against the cutting edge placed on its path. These obligate the current to sweep at times through the opening placed above the edge. Dilatations follow the condensations and the tube reinforces such vibrations as its length permits. Like some streams of water the explanation is clear only because of its being shallow and the thoughtful reader tries in vain to find out the cause of the transformation of a continuous into an alternating motion. The discovery in organ pipes of the air whirlwinds called Loolet's cyclones, which probably play a very important part in ordinary phonation, has still further complicated the problem and neither Helmholtz's theory of the pendular motion of air nor the works of his opponents, Friedrich Kruss and Washburn, have so far thrown much light upon it.

It is none the less interesting to note the change undergone in recent years by the classical whistles G, O and M shown on the accompanying figure. Several minor improvements are more applications of some well-known law of acoustics. Others are evidently the result of empirical research. Thus it is probable that whistles C, E and N owe their power to their shape, which highly favors the formation of Loolet's cyclones, but how and why is not thoroughly understood. Whistle C is but a freaky imitation of E. It remains silent in the hands of the unwary person who does not use his fingers as lateral walls for the uncomplete cylindrical bur. Whistles K and P embody an attempt to increase the volume of sound through an extension of the cutting edge round the whole instrument. Both are noisy calls but require powerful lungs. In the scientific instrument called Galton's whistle (H) length of pipe may be made to vary through the motion of the end screw. Pitch varies accordingly and the whistle is used to ascertain the individual upper limit of audible sounds, as can produce those which cannot be heard, that is which result in over 40,000 vibrations per second. Pitch of whistles P and I can be made to vary, as in Galton's whistle, through changes in the length of pipe. In the American model, P, this is accomplished by merely pressing the rubber end of the whistle. The French whistle, I, is provided with a sliding end. In whistle B two different sounds are produced, through a change from open to closed pipe, on top of the whistle is an opening which can be closed with the finger. Two sounds are also produced by whistles A and L, but they are simultaneous and, according to the maker's whim, give either a harmonious duet or a rough sound with perceptible beats. In L the two tubes are side by side, in A they are superposed. D has been considerably flattened in the plane containing the cutting edge, not, probably, to take advantage of Savart's law but merely to allow the easy carrying of the whistle in a vest pocket. So far as the origin of sound is concerned P cannot be called a whistle, although it is used as such and gives a powerful whistling sound. It is probably the smallest reed ever made for practical purposes. It shows again that the characteristics of the whistling sound are in pitch only and not in quality, moderate and hard blowing gives a sound that cannot be distinguished from that of other whistles. With this little reed as with Galton's whistle, the upper limit of perceptible sounds can be reached. J is a hybrid instrument, whistle at one end and trumpet call at the other. The same can be said of P, which carries a compass on one side.

## Optical Phenomena Seen from Balloons

By C. Pittsburgh Talman

BENEDICT the optical phenomena of the atmosphere which ordinary mortals may enjoy from time to time—rainbows, coronas, halos, the colors of sunrise and sunset, mirages, etc.—there are two interesting spectacles of this kind which require, for their observation, an elevated point of view, and which are most favorably seen from balloons. These phenomena, especially when observed for the first time, usually make a profound impression upon the mind of the spectator, and have frequently been described in narratives of balloon voyages.

The commoner of these is the Brooken spoor. The reader is probably familiar with descriptions of this phenomenon as seen from the tops of mountains—namely, only the white-haired Brooken spoor, which other mountains the world over. The mountaineer sees his shadow cast upon a nearby bank of fog or cloud—an illusion of colossal dimensions, though this is an illusion, due to an overestimate of the distance of the shadow

from the observer. Surrounding the shadow there is often seen a circle of prismatic colors—technically called a *glory*—the center of which is that point in the shadow which corresponds with the position of the observer's eye. Hence, if the shadow is very near only the least suggestion of colored light, but if more distant the whole shadow is incased in the glory. This is one of several points in connection with the Brooken spoor that are not made clear in the ordinary descriptions of it; while the usual pictures (drawings) are even worse, for they give the impression that the shadow cast by a person

Classical, hybrid, scientific, practical and freak whistles.

whom we will call A, with its attendant glory, may be seen by another person, B, from almost any distance or angle of view. The truth is, that A's spoor and its rings can be seen only by himself, or by another standing very close to him. This is one illustration of the fact that drawings of nearly all the optical phenomena of the atmosphere are more often than not decidedly inaccurate and misleading, and point to the superiority, in certain respects, of the photograph—in which the artist's imagination and misconceptions can play no part. On the other hand, the photograph is usually an incomplete picture of the phenomenon, owing to the fact that the photographic plate is unequally sensitive to light of different colors, and may also fail to register phenomena of

Fig. 1.—Shadow of a balloon on the clouds, surrounded by rings of colored light.

feeble luminosity, as the time of exposure is often insufficient, on account of the evanescent character of the subjects in question.

We present herewith (Fig. 1) the only photograph of the Brooken spoor ever taken from a balloon. It was made by Dr. Alfred Wegner, of the University of Marburg, Germany, on May 8th, 1910. Here the "spoor" consists of the shadow, on the clouds, of the balloon and its basket; the latter surrounded by a brilliant aureole. The glory showed the usual series of colors, ranging from blue inside to red outside, and this series was twice repeated. In order to identify the colors on the photographic plate, Dr. Wegner photographed with a similar

plate the spectrum of light and observed the intensity of the lines produced by the different colors. It was thus found that violet made no impression on the plates; that red and blue were very weak; that yellow was very strong, etc. From the relative intensity of the different colors, the colors of the Brooken spoor could be able to reconstruct the colors with considerable accuracy, and to measure the angular width of the same revealed by each. The result was extremely interesting, as it showed some marked divergences from the theoretical dimensions of these rings as given in standard works on optics.

The moral of this experiment is that scientific ascertainment should heretofore make every effort to secure good photographs of the Brooken spoor, and in fact of all the optical phenomena of the atmosphere, in connection with which there are still many unsettled questions.

Fig. 2 is a photograph of the phenomenon of coronas, and is also the first of its kind. It was taken by Dr. Wegner on September 4th, 1910. There is very little literature concerning this phenomenon in English, and its name is unknown to the English dictionaries—although it was first described by the astronomer Bessel and Brink, in connection with their balloon ascent of July 27th, 1850, and is mentioned in the English translation of Flammarion's book "The Atmosphere," published as long ago as 1873. (See p. 144 of that work.) It is a bright image of the sun seen on a sheet of cloud lying below the observer—corresponding in position to the image as reflected in a sheet of water. (It is quite distinct from the two phenomena of the *cathelion*, *catenion*, or *catenion*, seen at the same altitude as the sun, but on the opposite side of the sky. This, again, is quite different from the catenion of the dictionary, for while the name *catenion* is now preferred by meteorologists, and which we have referred to above in connection with the Brooken spoor. The terminology of atmospheric optics has been so embroiled by unscientific lexicographers that in writing on this subject one is obliged to define nearly every term one uses.)

As to the explanation of the two phenomena described above, the colored rings of the Brooken spoor are produced by the diffraction of the sun's light around the dry drops of water or crystals of ice forming a cloud or fog. The phenomenon is the same as the coronas often seen about the moon when shining through feathery clouds, except that in the glory the light is not only dispersed by diffraction, but subsequently reflected to the eye of the observer. As the Brooken spoor is always diametrically opposite the sun, it can rarely be seen from a mountain top except when the sun is low, while from a balloon it may be seen at any altitude of the sun. If the sun is in the zenith the balloonist will see the spoor directly beneath him.

The *catenion* is a member of the numerous halo family. It is an image of the sun reflected from the upper horizontal surface of ice crystals, of which, at low temperatures, clouds are composed. It has occasionally been seen surrounded by a circular or elliptical halo, either the common halo of 22 degrees radius, or an extraordinary small halo having a radius of only from 14 to 2 degrees.

## Nomenclature of the Polar Regions

SIR CLEMENTS MARKHAM, writing in the *Geographical Journal*, takes exception to the custom of loading the maps of coast-lines in the polar regions with a multiplicity of "lands," belonging to a single geographical unit. Thus, the coast extending west from Ross Sea, in the Antarctic, has no less than thirteen "lands" strung along it, viz., Victoria, Adelaide, Sabrina, Wilkes (this name is also applied to the whole coast), North, Totten, Budd, Knox, Termination, Mackin, Whidbey, Kemp, Elderby, and Coast. The *Geographical Journal* does not mention a fourteenth, King George V, just added by the Maxon expedition, which has been exploring the coast in question. The writer also pays his respects to Amundsen (without naming him) in the emphatic statement that the great Antarctic Ice Cap was so named by Capt. Scott, his discoverer, and needs no other designation. It will be recalled that Amundsen named it the King Hanlon VII. Palace. To the first of the above-mentioned complaints the reply might be made that, as there are no towns in the polar regions, and as the natural topographic features are in many cases more or less obscure, the so-called "lands" serve as convenient points de repère. As it is, however, understood that the term "land" is never to be used, then "regions" or "districts" would do and imply a natural subdivision of the earth's surface.

The Mathematical Works of the late Isaac Newton are shortly to be published in Latin under the auspices of the Academy of Public Instruction and the University of Bologna.

**Work in Grade in the Coladera Cut**  
 Accompanying engraving pictures  
 An event that marks an epoch in the  
 history of the Panama Canal. On the  
 afternoon of May 20th, 1913, steam shovel  
 No. 828 from the north and shovel No.  
 220 from the south, each working on the  
 floor of the canal, met opposite the town  
 of Coladera, completing a channel at the  
 bottom level of the canal the entire length  
 of Coladera Cut. The canal will be com-  
 pleted when this channel has been wid-  
 ened to the required bottom width of 800  
 feet. To complicate matters several million  
 cubic yards of material is being contribu-  
 ted by the various slides located near the  
 Continental divide, where the cut is  
 deepest. Col. Goetzlows plans to continue  
 the excavation by steam shovels until Oc-  
 tober or November, 1913, when the cut  
 will be flooded and the remaining excava-  
 tion will be taken care of by dredges. Ves-  
 sels of moderate draft may be permitted  
 to use the canal soon after the flooding  
 of Coladera Cut.

Meeting of the north and south excavation on the bottom level of Coladera.

### Clearing a Bridge Wreck With the Oxy-acetylene Torch

**INDIANAPOLIS** has recently been en-  
 gaged in removing with fire the wreck  
 age caused by flood waters. Two bridges  
 which crossed White River and Fall  
 Creek, respectively, were badly damaged  
 during the recent flood. Both bridges  
 were of stone and concrete with a frame-  
 work of heavy steel girders, and when  
 they went down these supports were re-  
 duced to a mass of twisted junk, but with-  
 stood all efforts to remove them. Finally,  
 the city engineers solved the problem of  
 cutting away the steel wreckage by calling  
 upon a company of that city that makes  
 a well known automobile acetylene light  
 ing system. In response to the appeal,  
 two oxy-acetylene welding outfits were  
 carried to the bridge and put into opera-  
 tion with cutting torch attachments. The  
 steel girders were quickly severed. The  
 entire work of cutting away the twisted  
 mass of wreckage took only three days.  
 With the cutting torch the girders were  
 first heated and then a stream of pure  
 oxygen was directed against the hot metal.  
 This caused the steel to burn quickly and  
 safely. The average time consumed in  
 cutting a girder was a little over five  
 minutes. The entire apparatus was  
 mounted on a light two-wheeled truck.  
 This feature of portability has made the  
 oxy-acetylene system of welding and cut-  
 ting very desirable in cases where rapid  
 work is necessary.

Cutting bridge girders with the oxy-acetylene torch.

### The Siamese King's Fire Engine

**THE** King of Siam recently ordered an  
 up-to-date fire engine, but he did not  
 care to have it self propelled or even pro-  
 vided with tongue or shafts for horse  
 transportation, and so, although a gas-  
 line engine is used to drive the fire pump,  
 the machine has to be hauled to the fire  
 by hand. Such a fire engine may strike  
 us as ridiculous, but it is a sensible ap-  
 paratus where the machine does not have  
 to be hauled a great distance. In fact,  
 fire engines of this type have been de-  
 veloped in England. One of them is em-  
 ployed by the Great Eastern Railway for pro-  
 tecting its property. It is considered hardly  
 worth while to provide the machine with  
 motor propulsion, as no long trips would  
 ever be demanded of it. The fire engine  
 illustrated herewith which is to be used  
 for the protection of the Royal Palace at  
 Bangkok, is fitted with a 45 to 80 horse-  
 power, 4-cylinder engine, driving a 2-stage,  
 800-gallon turbine pump. The whole ap-  
 paratus weighs about one ton.

A hand-down gasoline fire engine for Siam.

### Night Golf Putting Course

By T. J. Linn, Jr.

LAST year an article was published in  
 the *Scientific American* concerning  
 the lighting of the tennis courts  
 at the Woodbury Country Club, Wood-  
 bury, N. J. This was probably the first  
 artificial illumination, of any kind, in  
 the country to be made in subject that is re-

Golf putting course lighted by gas arcs.

ferred to the writer that it would be a  
 good scheme to extend this field of arti-  
 ficial illumination to include the lighting  
 of a golf putting course.

The course is laid out on a plot of  
 ground 40 by 90 feet and contains nine  
 holes. It must be evident that night play-  
 ing on such a course is highly desirable.  
 In the first place, only a limited area has  
 to be lighted. In the second place it  
 makes it possible for business men and  
 others who have not sufficient time dur-  
 ing the day at their disposal to practice-  
 putting or to play a putting match at  
 night. A night tournament has already  
 been played.

The installation of the lamps is com-  
 paratively simple. Two wrought iron  
 posts are used and two lamps are  
 suspended from the ends of a long cross  
 arm on the top of the posts. Four 5  
 mantle multi-flex inverted gas arcs are  
 used to light the course. To reduce glare  
 opaline globes were used on the lamps.  
 A fairly uniform distribution of light over  
 the course is desirable, the principal  
 requisite, of course, being to have the  
 nine holes uniformly lighted. This was  
 accomplished by spacing the holes so that  
 they were not more than 10 feet hori-  
 zontally distant from the lamps. The  
 lamps are equipped with standard dis-  
 tributing reflectors, for it was found that  
 the players not only desired to play on  
 the course itself, but to approach the  
 course with a mallet, and it is possible  
 to do this at a distance of at least 100  
 feet. The intensity at various holes is ap-  
 proximately 2 1/2 foot-candles. The holes  
 are painted white inside to make them  
 easily visible from any part of the course.  
 To get a good idea of the ample illumina-  
 tion provided, it might be stated that it  
 is considerably higher than that on the  
 floor of an ordinary house at night as it  
 is usually lighted.

The remarkably uniform illumination  
 is shown by the accompanying photograph,  
 which was made by the light of the lamps  
 alone on a dark night with an exposure  
 of 1 1/2 minutes.

The cost of lighting this golf putting  
 course is 1 1/2 cents per hour for the gas  
 consumed for the entire four lamps, each  
 lamp consuming from 18 to 20 cubic feet  
 of gas per hour, and the cost of gas in  
 Woodbury being 90 cents per thousand  
 cubic feet.

### Automobile Traction in Italy

**THE** Italian government recently gave  
 as a striking proof of the favor which  
 automobile traction is meeting with in  
 that country, by deciding to allow sub-  
 sidies for the establishment of new power  
 wagon or autobus lines in addition to  
 what are now being operated in that  
 country so that in the near future there  
 will be twenty four new automobile lines  
 operated. Their object is to give a direct  
 connection between isolated villages and  
 the industrial centers or at least to con-  
 nect them with the nearest railroad sta-  
 tion, and thus advance progress by the  
 traffic facilities afforded. Several lines  
 which are to be used for places where  
 commerce is becoming developed, are laid  
 out for freight transport by medium  
 sized power wagons, and this is an inter-  
 esting example for generally such lines  
 were designed for passenger and baggage  
 service only. The new power wagon lines  
 will foot up a total distance of 520 miles,  
 and will cover rough country in many  
 cases. Such a reification of the rail-  
 road lines, as it may be termed will give  
 the greatest service in opening up the  
 country to trade in general to be a result  
 of the rapid progress made in power wa-  
 gon matters in Italy the government is  
 taking up the question of road made and  
 will go into extensive improvements which  
 will require about \$1,000,000 for the new  
 set stamp of the work. As in the case of  
 other European countries, the power  
 wagon lines will penetrate into parts of  
 the country where railroads could not be  
 run owing to the nature of the ground,  
 and thus each locality will be brought in  
 to a disadvantageous position.

## Inventions New and Interesting

Simple Patent Law; Patent Office News; Notes on Trademarks

### A Silencer for Gas Engines

**F**OLLOWING his well known invention of the silencer for rifles, Mr. Hiram Percy Maxim turned his attention to the noisy exhaust of the gas engine and has evolved a silencer which will muffle or soften that noise and smother out the sharp gas engine impulses. The silencer consists of a nested series of spiral shells between which are formed spiral whirl chambers, that the exhaust must traverse in order to increase the silencing effect these spiral whirl chambers are alternately reversed in direction, so that the gases in passing through them must travel alternately in a right handed and in a left handed direction. The spiral shells are progressively larger, permitting the gases to expand. The arrangement of the spiral shells is shown in the accompanying drawing. They are inclosed in a cylindrical casing. At the inlet end of the silencer, there is an end plate *A* formed with flanges *A'*. Near the outlet end of the silencer is a support *B*, also formed with annular flanges *B'*. The shells *C* are mounted between the plate *A* and support *B*, and are fitted between the flanges. The parts are held in place by means of long bolts *D*, which pass from the plate *A* through the support *B* and the end plate *A*. The bodies of these bolts are flattened where they pass between the spiral shells, so as to offer as little resistance as possible to the flow of gases. They may be seen in section in the enlarged view of the silencer. It will be observed that the spiral shells are formed withlapping ends to provide discharge throats to the succeeding whirl chambers. The shells are so arranged that each discharge throat is singularly advanced in the discharging direction beyond that of the succeeding whirl chamber. In some types of these silencers, certain of the spiral shells, particularly the outer ones, are casted, so as to retard the flow of the gases. The arrows indicate the course of the gases through the silencer. They enter at *E*, and pass successively through the whirl chambers, finally leaving into the chamber formed between the outer spiral shell and the wall of the casing. Thence they pass over the end of the support *B*, and out through the exhaust port *G*. In the end plate *A*, a passage *H* is formed, through which cooling water may be admitted to the first whirl chamber of the silencer. In the opposite end plate *F* there is a port *J* adapted to be fitted with a drip connection for the discharge of the cooling fluid from the silencer.

### Moving Pictures at Home

**T**HE public entertainment possesses this disadvantage that it must suit a heterogeneous assembly of people of varied interests and tastes. Consequently, its programme must be made up of a variety of subjects which may not altogether satisfy any one of the audience or spectators. If the entertainment is a concert a disappointed listener can at least go home and make up the deficiency with his own piano, player piano or phonograph or on the other hand if one has heard something that particularly strikes his fancy he may purchase the selection and reproduce it to his heart's content at home. In the case of the moving picture show, however, the spectator is obliged to accept a whole show's programme even though prepared for a public whose tastes are absolutely at variance with his own, on the chance of witnessing now and then a selection that he finds interesting and instructive. But he cannot reproduce those selections or make up his own programme at home, at least he has not been able to do so heretofore, for the reason

Nested spiral whirl chambers to silence gas engine exhaust.

A home cinematograph, which generates its own current.

Diagram showing the action of the soft palate in directing a part of the breath in gases through the nasal passage (arrow at left) or closing off the nasal passage and directing the entire stream out through the mouth (as shown on right). Two mirrors placed below the nose, the other below the mouth, catch the breath and thereby indicate the relative strength of the two streams.

Dr. Glover using his transmitter with non-piano attachments.

that up to the present time there have been no practical cinematographs for home use. Although a machine of this character was placed on the market a year or two ago, it was found deficient in a number of respects and was finally withdrawn by the manufacturer. Now, however, a hand-operated home cinematograph has just been put on the market which is very promising. It is manufactured by a well-known foreign cinematograph company and has already met with great success abroad. The machine is shown in the accompanying photograph.

One of the first questions that occurs to a man who is contemplating the introduction of a cinematograph into his home is the danger of fire. The new machine employs fireproof films made of acetate cellulose and to make sure that the owner may not attempt to use the highly inflammable films of the commercial machine, it is designed to take a special form of film which can be had from the manufacturers only.

The source of light is another important question. In the machine which was withdrawn from the market because it proved to be impracticable, a carbon arc lamp was employed. This called for much heavier current than could be obtained without a special circuit. In the new cinematograph no connection with the lighting circuit is necessary for the machine generates its own current in sufficient quantity to light a small osram lamp.

The generator, which is in the form of a magneto, may be seen in the foreground of the accompanying photograph. It is operated through suitable gearing by a crank handle and is fitted with a governor to prevent excessive velocity of the armature. The osram lamp is placed in small light-tight casing fitted with a reflector and condenser. So little heat is generated that there is no possible danger of injuring the film, particularly when we realize that the flow of current and feed of the film are effected by one and the same crank handle so that the film cannot be stalled without arresting the flow of current as well.

The film is given an intermittent motion in front of the lamp by mechanism similar to that employed in the commercial machine. Very little effort is required to operate the machine. It projects a picture measuring about three by four feet at a distance of ten or twelve feet, the exact dimensions depending, within limits, upon the distance of the screen from the camera. Hence the machine may conveniently be used in the ordinary parlor or sitting room. A large library of films has already been prepared for this machine, including in addition to those of the customary dramatic and vaudeville type of exhibition, a wide variety of educational subjects, which should make an instrument of this sort particularly valuable in the class room.

### An Intensifier for Telephone Transmission

By Jacques Berroyer

**H**AS it ever occurred to the reader that there is something very artificial about our present methods of speaking over the telephone? The microphone is so constructed that it catches only the sounds which proceed directly from the mouth, whereas in actual speech, a not inconsiderable portion of the sounds emitted are carried now or less completely through the nose. It has, therefore, been almost completely lost in an ordinary telephone conversation, and we are thus, therefore, not so surprised at the voice being

over the glass, although recognizable as such announced to the instrument, nevertheless differs materially from that of ordinary speech.

Scientific telephone engineers, in attacking the problem of increasing the distinctness of transmission of the voice over the telephone, have mainly concentrated their attention upon improvements in the construction of the microphone, or else upon improvements in the design of the telephone plate. No one, until recently, seems to have paid much attention to the study of the human voice and its production, with a view to applying the observations thus obtained for perfecting telephony. It is by starting from such a basis as this that Dr. Julius Glover has evolved an apparatus shown in our illustration, by the aid of which the sound carried over the wire is much intensified and the clearness of speech is greatly increased, a matter which is of no small importance, especially for long distance transmission.

Inasmuch as in the telephone the electric current reacts upon the magnet in the receiver, not so much by its intensity, but by the variations in its intensity, it is necessary, if the latter is to act as perfect as possible a reproducing of the sound impressed upon the transmitter, to reproduce as exactly as possible all the modulations of the voice. To realize just what this implies, we must bear in mind the construction of our throat. On passing from the pharynx the sound wave impinge upon the soft palate, which divides them into two unequal parts, of which the one escapes through the nose, while the other issues at the mouth (see our illustration). Evidently to obtain a perfect result, it is necessary that each of these two groups of sound waves be transmitted in proper proportion over the telephone, while as the matter of fact, according to photographic means the variations in the intensity of the microphone current, which can be done by the aid of an otolaryngist, a simpler means to effect the same end, perhaps less perfectly, is to force the constrictions of the throat from the mouth and nose by means of mirrors or other suitable device. It is found that the records so obtained for the mouth and nose differ for the same word, according to a difference of speech.

In the improved telephone invented by Dr. Glover, contrary to the usual custom, the entire voice assists in producing the electro-magnetic phenomena by the aid of which speech is transmitted. The new apparatus differs from the customary form in that it possesses two microphone transmitters one for the mouth and one for the nose, each of properly adjusted sensibility. The output of each transmitter is attached to a handle as in the ordinary telephone.

Microphones of this kind can be used directly in the primary without conversion battery and without the use of any other apparatus function perfectly by the use of a single central battery, giving 24 volts or less. The uniform resistance has a total of 150 ohms, which, however, can be adjusted to suit circumstances. The entire coil can be utilized as the variations in the intensity of the current due to the voice are found to be sufficiently accentuated without it. Nevertheless, transmission is somewhat assisted by the use of the coil.

As a matter of hygiene, a roll of tissue paper may be passed in front of the mouth and nose to prevent any possible infection, the tissue paper being renewed automatically at each call.

**A School Child Inventor.**—A school girl attending the Braden High School in Washington City realizing the need of a pocket, overhauling her school bag, discovered in a corner of her own invention in which she had formed pockets at other

sides. One pocket was adapted for carrying small change and the other for carrying a lead pencil or similar small articles.

### The Supreme Court of the United States on Price Maintenance

**THE** right of the patentee to fix the retail price of articles embodying his invention and to treat as an infringement of his patent any attempt to sell at other prices has now been squarely passed upon by the Supreme Court of the United States in *Bloomer v. The Bazaar Chemical Company & James O'Donnell*. In legal history this will be known as the *Bloomer Case*. The decision of the Supreme Court is of immense importance to the public, to retailers and to manufacturers. It denies absolutely the right of a patentee to control the selling price of his goods and to leave his hands. The following is an abstract of the decision.—[Editor.]

The right to make, use and sell an invented article is not derived from the patent law. The rights accrue before and without the passage of the law and was always the right of an inventor. The act secured to the inventor the exclusive right to make, use and vend the thing patented, and consequently the law, without considering like privileges without the consent of the patentee. *Bloomer v. McQueen*, 14 How. 539, 540, *Continental Paper Bag Company v. Eastern Paper Bag Company*, 210 U. S. 405. It was passed for the purpose of encouraging useful invention and promoting new and useful improvements by the protection and stimulation thereby given to inventive patent law. The rights accrue to the public, after the lapse of the exclusive privileges granted, the benefit of such inventions and improvements. With these beneficent purposes in view the act of Congress should be interpreted even liberally construed, yet, while this principle is generally recognized, care should be taken not to extend by judicial construction the rights and privileges which it was the purpose of the act to confer.

In framing the act and defining the extent of the rights and privileges secured to a patentee Congress did not use technical or occult phrases, but in simple terms gave an inventor the exclusive right to make, use and vend his invention of a definite term of years. The right to make can scarcely be made plainer by definition, and embraces the construction of the thing invented. The right to use is the comprehensive term and embraces within its meaning the right to put into service any given invention. And Congress did not stop with the express grant of the rights to make and to use. Recognizing that many inventions would be valuable to the inventor because of sales of the patented machine or device to others, it granted also the exclusive right to vend the invention secured by his patent. To vend is a term readily understood and of no doubtful import. Its use in the statute secured to the inventor the exclusive right to transfer the title for a consideration to whomever he pleased in order to make, use and vend, fully constructed, with a view to making the purpose of Congress effectual, reads the extent of the patent monopoly under the statute of the United States. *Bloomer v. McQueen*, 14 How. 540.

The case presented parties to goods purchased by jobbers within the District of Columbia and sold to the appellee at prices not stated, and would by him at retail at less than the price of one dollar fixed in the notice. The question therefore now before this court for judicial determination is, May a patentee by notice limit the price at which his patented article may be sold, and if such article may be made, such article being in the hands of a retailer by purchase from a jobber who has paid to the agent of the patentee the full price asked for the article sold? The object of the notice is said to be to effectually maintain prices and to prevent ruinous competition by the cutting of prices in sales of the patented article.

That such purpose could not be accomplished by agreements concerning articles not protected by the patent monopoly was settled by this court in the case of *Dr. Miles v. Park & Sons Company*, 220 U. S. 373, in which it was held that an attempt to thus fix the price of an article of general use would be against public policy and void. It was doubtless within the power of Congress to confer such right of restriction upon a patentee. Has it done so? The question has not been determined in any previous case in this court, so far as we are aware. It was dealt with under the copyright statute, however, in the case of *Merrill Company v. Stratus*, 210 U. S. 359. In that case it was undertaken to limit the price of copyrighted books for sale at retail by a notice on each book fixing the price at one dollar and stating that no dealer was licensed to sell it for less and that a sale at a low price would be treated as an infringement of the copyright. It was there held that such notice, in securing to the holder of the copyright the exclusive right to vend copies of the book, conferred a privilege which, when the book was sold, was exercised by the holder, and that the right secured by the statute was thereby exhausted. The court also held that it was not the purpose of the law to grant the further right to qualify the title of future purchasers by means of the notice, and that to give such right would extend the statute beyond its fair meaning and secure privileges not intended to be covered by the act of Congress.

It was there cited *Revived Statute*, a part of the copyright act, securing to an author, inventor, designer or proprietor of books, maps, charts or dramatic or musical compositions the sole liberty of printing, reprinting, publishing, selling, copying, circulating, finishing and vending the same. While that statute differs from the patent statute in terms and in the subject matter intended to be protected, it is apparent in the respect stated that the two inquiries are of a strong similarity between and identity of purpose in the two statutes. In the case of patents the exclusive right to vend the invention or discovery is added to the right to make and use the subject-matter of the grant, and in the case of copyrights the sole right of multiplying and reproducing books and other compositions is coupled with the exclusive right of sale. So far as the use of the terms "vend" and "selling" is concerned, the protection intended to be secured is substantially identical. The sale of a patented article is not essentially different from the sale of a book. In each case to vend is to part with the thing for a consideration.

It is apparent that the principal difference in the enactments lies in the presence of the word "invent" in the patent statute and its absence in the copyright law. An inventor has not only the exclusive right to make and vend his invention or discovery, but he has the like right to use it, and when a case comes fairly within the patent statute, the right to use, that should be protected by all means properly within the scope of the statute.

Chief Justice, however, of the plaintiff in this case is upon the record. He is of the opinion in that case shows that the restriction was sustained because of the patent statute, distinguishing in that respect the patent from the copyright act. In that case a patented micrograph had been sold which bore an inscription in the form of a notice that the machine was patented and that the user was restricted; it might only be used with stands, ink and other supplies made by the A. B. Dick Company, the owners of the patent. The alleged infringer sold to the purchaser a machine in the use of ink suitable for use with the machine with full knowledge of the restriction and with the expectation that the ink sold would be used in connection with the machine. It is expressly

stated in the opinion that the machine was sold at cost or less and that the patentee depended upon the profit realized from the sale of the non-patented articles to be used with the machine for the profit which he expected to realize from his invention (224 U. S. 26). After commenting upon the copyright statutes and the resemblance between the author's right to vend copies of his work and the patentee to vend copies of his invention, the chief justice's right to vend the patented thing, it was said (page 40)

"The inventor by section 488 *Revived Statute* has the right to vend copies of his work to make, use and vend the invention or discovery. This grant, as defined in *Bloomer v. McQueen*, 14 How. 540, confers no restriction in the right to exclude every one from making using or vending the thing patented. Thus, there are several restrictive rights, and each is the subject of subdivision so that one person may be permitted to make but neither to sell nor use the patented thing. To authorize may be conferred the right to sell but with a limited sale, or in a particular use, while to another the patentee may grant only the right to make and use, or to use only for specific purposes. Adams v. *Wall*, 444 U. S. 701. *Revived Statute* v. *Wall*, 444 U. S. 701. (Italics in the original opinion.)

That case was distinguished from *Bloomer*. It was there held that the copyright act, because of the difference in the terms of the copyright and patent statutes, the patent act conferring not only the right to make and sell but the right to vend the thing patented, the patent of the patent. It was under the right to use that the license notice in question was sustained and it is obvious that the notice in the case dealt with the use of the machine and the right to use the machine with the paper, ink and supplies of the manufacture of the patentee. While the title was transferred it was a qualified title, giving a right to use the machine only with certain restrictions. It was there held that the Dick case that "there is no collision whatever between the decision in the *Bloomer* case and the present opinion. Each rests upon a construction of the applicable statute and the result is different."

It is contended in argument that the notice in this case deals with the use of the invention, because the notice states that the package is licensed for sale and use at a price of not less than one dollar, that a purchase is an acceptance of the conditions, and that all rights revert to the patentee in event of violation of the restriction. But in view of the facts certified in this case, as to what took place concerning the article in question, it is a perversion of terms to call the transaction in any sense a license to use the invention. The jobber from whom the appellee purchased had previously bought, at a price which must be deemed to have been satisfactory, the packages of *Stanston* afterward sold to the appellee. The patentee had no interest in the proceeds of the sale of the subject-matter of the royalty thereon or to participation in the profits thereof. The packages were sold with as full and complete title as any article could have when sold in the open market, and the restriction was not to limit the sale or use when sold for not less than one dollar. In other words, the title transferred was full and complete with an attempt to reserve the right to the price at which subsequent sales could be made. There is no showing of a qualified sale for less than value for limited use under other articles only, as was shown in the *Bloomer* case. There is no showing of a limited right to use this invention, and to call the sale a license to use is a mere play upon words.

The real question is whether in the exercise of the right secured by statute to "vend" a patented article there is included the right, by notice, to dictate the price at which subsequent sales of the article may be made. The patentee relies solely upon the notice quoted to control future prices of the article. It is contended that the sale is to be of great utility and highly desirable for general use. The appellee and the jobbers from whom he purchased were neither the agents nor the licensees of the

(Continued on page 547)

## UNITED STATES TIRES ARE GOOD TIRES

There's not a closer tire built

## How many good points should a good tire have?

You know the qualities a good tire ought to have. Generous mileage is the prime essential.

You want a guarantee against rim cuts; you want flexibility, ease of manipulation and security of fastening.

Have you ever been able to secure all these desirable qualities in one tire? Probably not.

Single factory companies have generally been content to strengthen their tires at only one or two of these points.

But by our four-factory co-operative methods of tire building we have been able to combine into one tire all of the desirable features it is possible to put into a tire.

## We have raised tire mileage to an unprecedented point

We have perfected and control exclusively a process that has increased the fabric strength of our tires practically fifty per cent. The tread on United States Tires are made of the toughest, longest wearing rubber stock ever put into an automobile tire. Flexibility and resilience have been improved to a similar degree.

In fact we have taken all the features that you yourself would like to find in the tires you buy and have put them all into one tire.

Made in three treads, Plain, Chain and Nobby, and in three styles of fastening including the Dunlop (Straight Side)

Cost no more than you are able to pay for other kinds

United States Tire Co., New York

tempts have been made to apply it to the cure of tuberculosis, but this species have been most discouraging. The most recent of these attempts, that of Friedmann, is now on trial. His bacteriologic differs from those heretofore employed in that he uses living instead of dead tubercle bacilli. It will be recalled that Pasteur sought to produce a very mild attack of anthrax in his animals by using an anthrax bacillus which had been artificially weakened. Similarly, Friedmann's use of tubercle bacilli obtained from a turtle, have been so changed as to be no longer virulent for man. Whether this form of treatment will prove to be successful or not remains to be seen; the results thus far are not encouraging.

In this connection it may be well to remember what has already been said concerning the strict specificity of the action of all these substances. Injections of tubercle bacilli are of no avail in the treatment of diphtheria, or of cholera. Similarly in tuberculosis nothing can be hoped for from injections of bacilli merely resembling tubercle bacilli, and there is some question whether these bacilli from the turtle really belong to the same family as the true tubercle bacilli which cause consumption. But even if they are true tubercle bacilli, it by no means follows that this represents the "cure" scientists have so long been seeking. From what has gone before it is obvious that treatment with specific and virulent is premised on the assumption that the development of antibodies represents the cure of the disease. This assumption, however, is open to criticism, for expert men have taught us that with the development of the antibodies, only one of the curative factors has been brought into existence. To be sure, in many infectious diseases, the antibodies that the body produces, the other factors are practically negligible. In other cases, however, something more than the mere presence of the specific antibodies is apparently needed in order to cure disease. This is the result thus far obtained with various forms of serum and vaccine treatment in tuberculosis make it likely that important causative factors remain unaffected by this form of treatment.

In concluding this brief sketch it may be added that a delicate but rather complicated serum reaction is now made use of in the diagnosis of venereal infections, and has thrown a great deal of light on the cause of such diseases as locomotor ataxia and general paresis. Another serum test is extensively used to the examination of blood stains for medico-legal purposes, by its use human blood stains can positively be differentiated from those of the lower animals. The same test is used in the examination of sewage and the like in order to detect horse or dog feces. A number of observers have devised methods of diagnosing cancer by means of serum reactions, but up to now some of these have proven reliable. All in all, these immunity studies have proven one of the most fruitful fields of medical research.

Three Patents for Steel Improvements.—Benjamin Talbot of Woodburn, Washington, has secured patents No. 1,055,831, 1,055,832 and 1,055,833, relating to improvements in steel. The patent No. 1,055,831 is for a process of treating steel ingots for the purpose of eliminating or reducing "paper" or scale in carrying out the process, the ingot is stripped from the mold while its interior is still fluid and the ingot is heated to soften its outer strata and then quenched to reduce its outer strata and of the ingot. The patent No. 1,055,832 is along the line of No. 1,055,831, with improvements facilitating the rolling of the ingot into the shape of a rail. The patent No. 1,055,833 relates to a steel roll or other object with a polished, heated top layer in carbon than the outer strata, thus improving the surface to free it from scale and defects and give it a uniformly tough interior layer in carbon steel the outer part.

The purpose of this journal is to record accurately, promptly, and intelligently, the progress of science, scientific knowledge and industrial achievement.

## The Need of an Automatic Stop

**F**ATE seems to have singled out the New York New Haven and Hartford Railroad Company to teach the need of an automatic final stop. In the course of the last two years—four June 24, 1915 to June 12th, 1917—there have been no less than thirty accidents on that unfortunate road—thirteen accidents in which forty eight persons were killed and hundreds injured. The sheer carelessness of engineers was responsible for part of the trouble, and speeded up rails, short crossovers, inoperative signals and other defective equipment for the rest. The last accident, a rear-end collision in which six were killed was no primary due to defective equipment.

In his testimony at the coroner's inquest, the engineer who was held responsible told a story which was substantiated, absolved him of carelessness. Absolutely nothing would have been to drive a fast passenger locomotive—he was a promoted driver who had handled a powerful express engine only a few times—he had been placed in the end of a new and exceptionally heavy Pullman engine, the airbrakes of which had been reported defective. He testified that he obeyed both the distant and the home signals and that he was in the rear of the scene of the accident, in starting off his train and applying his airbrakes. Either because the airbrake equipment was not adapted to this grossly overloaded locomotive and the tight cars behind it or because it was out of order the train rushed on. The engineer saved the truck, his whole and finally tried to reverse the power, but was unable to do so because of his physical inability to move the stiff reversing lever sufficiently. The brakes of the rear cars apparently did better than those of the forward cars.

Something can be learned from this disaster. Engine drivers must always remember that the train is moving over a power. Pondering over the fact that the airbrakes seem to have unaccountably failed and that instead of a steel couch, a wooden parlor car had to bear the brunt of the shock, with the fatalities resulting in which we have recently counted, again the necessity of relying on an automatic airbrake, which will act independently of an engineer's driven home with truck force.

No doubt the New Haven reads interest in automatic stops evidenced by its offer of a substantial thousand dollar offer for a suitable appliance will be heightened by this latest catastrophe. The railroad was as inventors in general will surely profit by a close study of the circumstances that surrounded the collision. We must admit that we know of no automatic stop, otherwise unobjectionable which would have averted this particular collision for the reason that most stops do not shut off the power but simply act on the air brake system and sound or display a signal. Only a stop which would reverse the power would be of any service in an airbrake power inoperative at the crucial moment.

## Agriculture in the High Schools

**T**HE plan of teaching agriculture in the secondary schools is spreading over the country with remarkable rapidity—so much so, in fact that it is very difficult to find enough teachers qualified to

give such instruction, to say nothing of the lack of suitable equipment and other material difficulties. Agriculture, however, has now a foothold in the schools and agricultural instruction in the common schools is no novelty. On the other hand, agriculture in the high schools may still be regarded as experimental, though it will soon cease to be so. This subject has just been investigated and reported upon by the United States Department of Education. From the report it appears that as recently as the school year 1900-07 less than one hundred public secondary schools, either special or general, gave agricultural instruction, even by means of simple experiments. In 1910 about 3,600 schools reported that agriculture was taught as a separate study in the high school department. It is true that in some of these cases the term "high school" was made to include the upper grades of the grammar school, but even making allowance for this fact it remains evident that there has been an immense increase in the number of true high schools in which distinct courses in agriculture are offered.

The first tentative steps in this direction date from the period between 1820 and 1860, during which there were a few attempts to introduce agricultural instruction into the ordinary academies, as well as some purely vocational experiments. From 1865 down to a very recent date the land grant colleges, established under the famous Morrill act of 1862, in addition to their regular college courses, did much work of a purely agricultural character. The Lafayette College, which in 1898 set out this work into a high school department, an example very largely followed since. About 1897-98 a large number of special agricultural high schools were established, but this practice has now declined somewhat in favor of the plan of granting State aid for the support of departments of agriculture or of agriculture and home economics, sometimes including manual training, in high schools already in existence.

Another token of progress is the increasing length of these high school courses in agriculture, which at the outset were mainly limited to one year. In the academic year 1911 to 1912 agricultural courses of two or more years were maintained locally in about 135 public schools, and by State aid in 176 more. This is in addition to 50 or more accurate special schools of agriculture and 54 secondary schools attached to the land grant colleges.

Lack of teachers has been the great difficulty ever since the introduction of special agricultural courses into the high schools began. When the textbook was introduced to supply the single teacher with a short summer course was sufficient to place out the general training of the science teacher or the practical farmer experience of the principal or superintendent. Now however, with high school courses extending over several years, and including the more elaborate field and judging operations, such meager training is inadequate. Within the last two or three years the idea has spread rapidly of establishing professorships of education in agricultural colleges, and professorships of agriculture in the new colleges of education (the general normal schools). Moreover, there are now grants in proved facilities for preparing instructors for high school agriculture in at least 37 of the land grant colleges, thanks chiefly to the so-called "Lansford" amendment to the agricultural appropriation bill approved March 4th, 1907, which provided that the portion of the funds appropriated thereby amounting now to \$25,000 annually, may be used by the land grant colleges for the special preparation of instructors for teaching the elements of agriculture and mechanic arts.

THE new provision has been fully solved during the past three years, with the agencies of text courses, especially written for secondary schools, including some on particular branches of agriculture for use in the advanced courses.

## An Optical Test for Mechanical Strains

**T**HE modern engineer has a wide field from which he can select the most suitable method for testing strains. The physicist is ready to place in his hands the most refined means of experimental observation. Thus, for example, it may often be sufficient to know the net result, as measured at the points of application, of a system of stresses exerted on a given structure or machine part. That how the strains are distributed the knowledge gained if we can actually look into the very core of the material of construction, and see the lines of strain. A simple application of physical principles enables us to do this. For a transparent material, such as glass, under strain, we can follow the passage of light differently in all directions. It becomes "optically active," as the physicist says, and rotates the plane of polarized light in a measure depending upon the magnitude of the strain. The effect can be rendered observable to the eye by the use of a Nicol's prism. In this way a glass model of a structure or machine to be tested gives us a valuable insight into the distribution of strains, primarily in the model, and

by inferring the distribution in the actual structure. It is true that the properties of glass will afford more or less freedom from them, but the method is not without its construction. While this will affect the results in their quantitative relation, they furnish very qualitative.

A series of tests of this character has been performed by Prof. R. G. Coker of the City and Guilds of London Technical College, and has reported upon before the sixth Congress of the International Association for Testing Materials. An account of these experiments will be found in this week's issue of our SUPPLEMENT. Prof. Coker applied the method in particular to the examination of cement, in which case he was employed in the same manner as in the case of glass. He found that the ratio of maximum stress to mean stress varies from 1.70 for the American standard to 1.75 for the English and 1.85 for the continental standards, respectively. These measurements indicate the vast of agreement in the stress distribution in the several standard types, and show what an important factor the form of the briquette is. This is just one application of a method which seems destined to find a very general field of utility.

## Genetic Research in Great Britain

**W** RITING of "The Progress of Mendelian Studies in Great Britain," a recently published Bulletin of Agricultural Intelligence of the International Institute of Agriculture, Prof. R. C. Punnett of Cambridge University shows how intense the activity has become in this comparatively new field, and what valuable results have already been obtained by British investigators. It happened that the well known work of Ralston and his colleagues, at Cambridge, coincided with the rapid rise of the School of Agriculture of the University, so that the new knowledge was immediately applied to practical purposes, especially in Prof. Ralston's experiments in crossing corn. Already improved strains have been developed and placed at the service of British farmers. The British government now subsidizes the researches in plant breeding at Cambridge, which have been extended to plants other than cereals, especially fruit trees. One important undertaking in progress here is the development of a potato naturally immune from *Phytophthora infestans* (potato blight), and success appears to be near at hand. The Cambridge experiments extend to insects and sheep. The best equipped British institution for the study of genetics is now the John Innes Horticultural Institution at Merton, near London, started in 1900 by Prof. Bateson, formerly of Cambridge, as its first director. Mr. H. H. Bateson, who has been working at this station, has established an experimental station at Burleigh near Leicester, where one of the most interesting experiments aims at the production of a pure race of sheep, known as the "Bateson" race, with a special aptitude for handling. Genetic research is also carried on by Prof. Keesel, at University College London, working on primulas by Mr. Stajewski-Browne, of Hampton near Oxford, who is working with pigeons, and by Dr. Trov of Cardiff. In Ireland, Prof. Wilson of Dublin has lately brought together a number of records dealing with the heredity of color in cattle and horses, and with the milking capacity of cows. Scotland has made a start by creating a lectureship in genetics at the University of Edinburgh.

## Investigating Atmospheric Pollution

**A** COMMITTEE has been formed with headquarters at London for the purpose of standardizing and co-ordinating the diverse methods in use in various parts of Great Britain for determining the degree of pollution of the atmosphere by dust and soot.

Understandings of this character include the investigations conducted by the Leasner in 1911 upon the soil fall of London, Prof. Cohen's experiments at Leeds; and those of the Corporation of London, and attempts have been made to introduce uniform methods, so that the measurements made in different places are not comparable. The committee has now decided to recommend two methods.

One of these methods is that successfully used in the inquiry conducted by the Leasner, in which a form of enlarged rain-gauge having a catchment area of four square feet received all rain, soot, and other deposits, and in which a large bottle was provided to collect them, so that they could be analyzed each month and the amount of solids settled estimated.

In the second method, which is much more complicated than the first, a measured volume of air is drawn through filter paper in a special apparatus, and the degree of discoloration of the paper measured. This method is used by the Corporation of London, and about two years, is intended to give measurements of the solid contents of the air from day to day, and from hour to hour.

# Engineering

**Investigating Railroad Accidents.**—A careful study of all accidents, no matter what their nature, has been made by the Pennsylvania Railroad, during the past year, and it has been found that probably 70 per cent of them could have been prevented if the employees had exercised special caution. This has led to the publication of a booklet entitled "Safety Hints and Suggestions for the Prevention of Personal Injury Accidents," by which it is hoped to educate the employees to a disposition to be careful, and to develop in them a sense of personal responsibility, not only for his own safety, but for that of his fellow employees as well.

**Largest Diesel Engine Vessel.**—The ship "Hagen" which is the largest vessel in the world to be propelled by Diesel oil engines, recently made her trial trip in the lower New York Bay. The vessel which was built for the Standard Oil Company measures 400 feet over all and has a displacement of 6,800 tons. She is equipped with two 6-cylinder Diesel engines of 2-cycle type, adapted to develop 2,400 horse-power at 140 revolutions per minute. At sea the steering engine is driven by compressed air. When nearing port, steam from a donkey boiler is used in the steering engine. The lighting is supplied by electricity and the living quarters are heated by a hot-water system, the water being heated by the main exhaust of the engine. During the test the vessel ran at about eleven knots.

**Death of Charles Henry Cramp.**—The former head of the shipbuilding firm of William Cramp & Sons died at the home of his son in Philadelphia, on June 24, at the age of 85. He was the son of William Cramp, who founded the firm of William Cramp & Sons on the Delaware river in 1820. Upon the death of William Cramp in 1879, Charles Henry Cramp became the head of the firm. He died much toward the building of the American navy. As he built in 1873, he built for the United States navy. The battleship "Maine," successor to the "Maine" that was destroyed in Havana Harbor, was built by the Cramps in 1902. It was Mr. Charles H. Cramp who suggested the "penalty system" by which a certain sum is deducted for every unit of force that the cylinder used in the contract. William C. Whitney, then Secretary of the Navy, accepted this suggestion and also introduced a premium system by which certain sums are paid in addition to the contract price if the performance exceeds the guarantee in the contract.

**Air Testing in Submarines.**—In order to determine the amount of carbon dioxide in the air in submarines, the device has been developed in Germany known as the "aerometer." It consists of a cylinder of nitrocellulose 4 inches in diameter and 4 inches high. It carries a scale for the liquid in a U-shaped glass tube which indicates the carbonic-acid content of the air in the cylinder as tested by an air-tight lid. Through the lid passes a thin tube with locking wheel which transmits to the outside air the air tension produced on closing the cylinder. The nickel-plated inside wall and bottom of the cylinder are lined with moist-filter paper. The air within the cylinder which is to be tested communicates with one branch of the U-tube while the other is open to the outside air. In the lid of the cylinder is placed a cartridge for absorbing carbonic acid. This cartridge remains closed while the apparatus is opened to admit the atmosphere that it is to be tested. After covering the lid, the below the lid is referred to, the cartridge is made to fall into the lid to the bottom of the chamber, and as it absorbs the carbonic acid gas, the volume of air in the chamber is reduced by an amount which is indicated in the U-tube. A single cartridge may be used for ten ordinary air tests.

**Air Resistance in Simplex Tunnel.**—The question of air resistance in the Simplex tunnel has been investigated by Swiss engineer, R. Kichenmann. The energy required to run trains in the tunnel upon the electric line is 35 watt-hours per ton-kilometer, including the weight of the locomotive, and this high figure is due to air resistance within the tunnel. The tunnel is 14.7 feet wide at rail level and 18 feet high from line to roof, the area of section being 250 square feet. The two large electric motor-driven blast fans at the Brigues and meet in 3,850 cubic feet of air per second, and there are two corresponding exhaust fans at the other end. The resistance to the wind by gravity on the 1 per 1,000 maximum gradient between the tunnel ends cannot exceed a speed of 60 kilometers (37 miles) an hour, even when going in the same direction as the air current, for the action here resembles that of a sail-boat. He compares the results obtained within the tunnel with those of the train when run in the open air, and finds that at a speed of 25 kilometers (15.5 miles) an hour a train running in the tunnel with the air draught encounters less resistance than in the open air, being propelled by the air current. At speeds over this the resistance in the tunnel is greater than in the open air. Such resistance due to air will certainly be lessened when the second aded parallel tunnel comes to be built, for the pressure will then be balanced between the two ends of the train, as the tunnels will be 55 feet apart and the air will have more space over the train.

# Electricity

**Long Distance Wireless Telegraphy.**—According to a press report wireless telephone communications have successfully been established between Berlin and Vienna, a distance of 365 miles. The German station was at Nauen and the Austrian station on the roof of the Technological Institute Museum in Vienna.

**Wireless Station in the Arctic.**—The expedition which will leave New York on July 2nd or 3rd for the Arctic continent known as Crocker Land, is to carry with it a powerful wireless telegraph equipment. The generators will be operated by kerosene engines and a telefunken wireless system will be employed, having a range of 2,000 miles. The wireless apparatus will be installed on the north side of Flager Bay. This will enable the expedition to keep in touch with civilization and it will also permit of experiments with directed Hertzian waves under the ideal climatic conditions of the Arctic. At Flager Bay there will also be established a radio station.

The Output of Electrical Steel.—The Comité des Forges de France has compiled the following table of the world's output of electrical steel

	1909	1910.	1911
Germany and Luxembourg	17,773	30,188	50,854
Austria-Hungary	9,048	20,028	22,587
United States	18,702	23,141	29,105
France	9,515	15,445	20,100
Sweden	591	431	2,024

Total 47,689 122,233 128,610  
It will be observed that in all the countries there has been a steady increase in output except in the United States where the output for 1911 is 44 per cent less than that of 1910

**The New Electric Searchlight Projectors.**—Among the Allgemeine establishment of Berlin, are the most powerful yet to be produced, and their candle-power, which is too high for measurement, can only be estimated by hundreds of millions of candles. This is the new method of regulating the arc. The large carbons are now moved back and forth by small electric motors and suitable gears, current being applied to the motors by a set of relays which work according to a set of relays by the arc, thus securing an automatic adjustment of the arc length in the best way. The base of the projector contains other motors for all the searchlight movements, and a distant lever control is so designed that turning the lever in all directions will operate the projector, and the lever in all directions for pointing the beam. These searchlights will carry several miles and still give light enough to read by.

**The Vibrating Reed Method of showing the frequency of alternating currents is meeting with much favor at present on account of its simplicity and accurate working. As will be remembered, it consists of a set of reeds of different lengths of spring steel mounted in line before a long magnet carrying the current, each being tuned for a different pitch between 45 and 55 per second. Only one tongue can vibrate for any given pitch of the current, and the free and slightly upturned end of the reed expands out in an apparent broad line so as to be clearly seen when it vibrates. All the reed ends are on a dial in a line numbered in series so that when the current is at the standard rate of 50, for instance, this numbered reed is seen to vibrate. By using the reed in the same battery power can be given any over or under frequencies to a distant point. Another use is to mount the new Hiltbrand dial or recorder device over an office clock, connected by wire to the dynamo, so that the chief engineer can just how the machines are running.**

**Electric Heat-storage Stove.**—Perhaps the development of electrical cooking has not been greatly encouraged for the reason that most apparatus was employed at the very time when the load of the central station was highest. Recently an electrical stove has been invented which the central station manager should welcome for the very reason that it calls for a lot of electricity at the lowest rates of the day. The stove at the central station is not burdened with a peak load. The stove consists of a block of iron imbedded in heat insulating material. Within this block is an electrical heating unit. The surface of the iron block forms a smooth plate on which a cooking vessel may be placed. But normally when the stove is not in use it is covered by a lid, also filled with heat insulating material. As there is practically no outlet for the heat generated by the heating unit, the iron block is steadily heated, the temperature continuously rising until the stove is removed for a cooking vessel to be substituted. After one dish has been cooked, the cover is applied to the stove again and it is permitted to store heat until the next dish is to be cooked. As compared with the ordinary disk stove the heat-storage stove uses very little current.

# Science

**A Remarkable Natural Bridge in the Philippines.**—Recently discovered by Mr. Paul R. Fanning, is described in the *Philippine Journal of Science*. Although only about thirty miles south of Manila, it is believed never to have been visited before by white men, and it is the first large natural bridge reported in the Philippines. It is on the Lomibin stream, a couple of miles west of Siliang. The stream runs through a cañon and the space beneath the bridge forms a tunnel, about 35 feet broad and some 250 feet long. The floor of the bridge, now about 130 feet below the top of the bears evidence of having once been the bed of the latter.

**Minute X-ray Pictures.**—M. Pierra Goby appears to be the first to obtain photographs of very minute specimens by the use of X-rays, such as diatoms and the like which have about the size of a grain of sand. This he does by placing the specimens directly upon a photographic plate and allowing a perfectly vertical beam of the rays to fall from a bulb above, through a special tube so as to properly direct the rays on to the object. In this way he secures a very minute photograph of the interior structure of the specimens, and this can be enlarged many times so as to obtain a large view in which the structure is clearly visible.

**Carnation Feed.**—The more chemical analysis of a fertilizer does not always afford the proper measure of its benefit to the plant. Nitrogenous manures of various sorts may furnish the same amount of nitrogen and yet produce different results with flowers. This has been clearly shown in one of the largest greenhouses in this country where the carnation was sown as a carnation fertilizer with astounding results. In rapidity of growth, strength of stem and beauty of bloom the plants so treated outscored all others. The carnation manure was a fish waste is worked up into fertilizer in large quantities along the Middle Atlantic coast and to some extent along the Great Lakes. The cost is not unreasonable. In all probability there is some active plant stimulant in the fish that accounts for the results. Methyl amine is found in fish and this may be the active element.

**The Cooling Power of the Atmosphere** depends upon other things than its temperature and its temperature of the body cooled. Thus, the wind is an important factor, as is the radiating power of the body in question. Dr. J. R. Milne, of Edinburgh, has described to the Scottish Meteorological Society an instrument for measuring the rate of cooling of the human body. The instrument has a fixed temperature of 98.4 deg. Fahr. This is "blood heat," and appears to have been chosen in order that the readings of the instrument may be a measure of analogous effects upon the human body. The device consists of a cylinder of thin copper, insulated except for its hemispherical top with plaster of Paris. It is filled with paraffin oil, and the amount of electrical energy necessary to keep the oil at blood heat is continuously recorded. Hence may be deduced the loss of heat calories per square centimeter per second. Dr. Milne calls his device a "psychrometer." (Why not "psychrometer"? It is quite similar in principle to Frankenhauer's "homotherm" (*Zeitschrift für Biologie*, vol. 4, 1911, pp. 439-441), as well as to the order "dermoimeter" of A. Piche and several earlier instruments.

The International Meteorological Committee met in Rome, April 7th to 12th, and was attended by the directors of official meteorology in France, Prussia, Sweden, Switzerland, Italy, Denmark, Russia, Canada, Prussia, and Great Britain. The questions discussed included some that have aroused much controversy throughout the meteorological world during the last two or three years. At the request of the Russian Institute of Agriculture the subject of agricultural meteorology was fully canvassed, and a special commission was appointed to undertake further investigation in this line. Dr. Hesselund, president of the International Commission of Scientific Meteorology, gave an interesting account of the work recently done in aerology. It is proposed to arrange for a large number of upper-air soundings at far northern points in 1915 for comparison with those which are to be made by Amundsen during his drift across the north polar region. The Russian government will probably carry out upper-air observations at Yakutsk and Verkhoyansk, in Siberia, and will perhaps send aerological expeditions to Nova Zembla and the mouth of the Lena. The German scientific station in Spitzbergen will probably keep open long enough to co-operate in this undertaking, and it is likely that Stefansson's Arctic expedition will contribute its part. The much-mooted question of using dynamic units of pressure in meteorology was settled provisionally by the decision to use the millibar as the aerological observations in both millibars and millimeters. International agreement was finally reached on the question of uniform storm signals, those recommended at the two conferences held in London were adopted, with the exception of the night hurricane signal. The next international meteorological conference will be a "conference," to be held in 1915, probably in Holland.

# Thirty-six Hours Under Water

## A Submarine Propelled by Gasoline Engines While Submerged

By Charlton Lawrence Edholm

LAST week the newspapers contained telegraphic dispatches sent directly from a craft at the bottom of Long Beach harbor, California. The vessel was a submarine that was endeavoring to establish a world's record for submergence by staying down thirty-six hours as against the record then held by the *Oktopus*, which in 1907 remained under water twenty-four hours. The new submarine sank at 11 A. M. on Monday and promptly at 5 P. M. Tuesday rose to the surface with its new endurance record. It contained a crew of six men who were not in the least affected by their long imprisonment. Throughout the test they were able to communicate with the outside world by means of a cable.

The submarine is a 75-foot craft with 75-hp beam and weighs 43 tons. It differs materially from the more familiar types, the most striking innovation being the position of the propellers near the bow. It is claimed that by thus pulling instead of pushing the vessel through the water the tendency to dive too abruptly is eliminated.

The inventor is John M. Cope, who has been studying the building of submarines for many years and believes that his model will prove superior in many respects to those now in use. He claims a speed of from seventeen to eighteen knots for his vessel running submerged with a maximum speed on the surface of about 16 knots. There are various automatic controls for ventilating, regulating the depth, maintaining stability and steering, but the details of these devices are withheld pending the issue of patents. The nature of some of them may be observed in the photographs, as for instance the rudder, which resembles that of an aeroplane, the projection along the top of the craft resembling the dorsal fin of a fish etc.

A very important feature is the elimination of storage batteries, as the vessel is operated by gas engines, used during submergence as well as while on the surface. Two gasoline engines are used, each developing 110 horse-power. By a device of unique construction, the exhaust from the engines is expelled from the submarine while running under water, and an advantage of this system is that greater speed is obtainable while submerged than when running on the surface. Of course the use of gas engines under water necessitates the operation of a device to discharge the exhaust so completely that the air will not be vitiated, and the inventor's tests seem to indicate that he has solved this problem.

An air compressor and tanks for storing up 50,000 cubic feet of air with a pressure of 3,000 pounds form an essential part of the new submarine equipment.

On March 26th a test run was made at Long Beach with the following result: The boat was submerged to a depth of eighteen feet in a thirty-foot depth of water and was found to respond perfectly to her horizontal and vertical rudders, sinking, how fast or slow first at will of the inventor or rising and skimming on even keel. Three men made the initial trip: Mr. Cope, Chief Engineer Allen Hoar and Assistant Engineer Clifford Hansen. Later in the day, some newspaper men were taken on a trial trip, and they also reported the success of the engine operations and the purity of the air while they were submerged and the absence of gasoline fumes. Of course no tests for speed were made while in the harbor, but that records in that line will be made owing to the novel features in the general outline, position of the propellers and devices for securing maximum power from the engines.

Regarding the feature of elimination of gas fumes, Mr. Cope says: "By means of a special exhaust system, the engines, exhausting overhead against a back pressure of 2½ inches, all the while maintaining a

vacuum on the engine exhaust of 2½ inches. We have also run the engines under water with the valve on the outboard exhaust closed down, until the gauge showed a back pressure of 150 pounds, corresponding to

and his associates believe that there are great commercial possibilities in a vessel designed for the recovery of sunken treasure, and of course records are a constant of countless millions of dollars in goods that have been lost in wrecked ships, and in many cases the position of the wrecks is known with sufficient accuracy for a submarine to locate them. Regarding this, the inventor says: "We propose to build a boat capable of being submerged to a depth of 1,000 feet with perfect safety, and with a lifting capacity of 75 tons. With grappling hooks, or clam-shell dredges, and with large and powerful arc lights in cables in the bottom of the boat, it would be a feasible undertaking for men within the submarine to work effectively in recovering sunken treasure."

### Human Barometers

MUCH has been written on the relations between weather and disease, and in medical literature there is no lack of carefully drawn statistics showing the varying prevalence of particular diseases, the rise and fall of mortality, etc., side by side with others indicating the march of one or more of the meteorological elements. There is, however, one phase of this subject that has been strikingly neglected. Many human beings are not only sensitive not merely to the weather of to-day, but also to the weather of tomorrow. Arthritis, rheumatic and neuritic patients need no barometer or weather map to tell them when bad weather is approaching. Old wounds give trouble at such a time, and members long since amputated remark their power to sense pain. These phenomena are so well known that it would be sheer fatuity in any scientific man to deny them, merely because he cannot understand them, yet strangely enough they have been the subject of very little systematic investigation.

A special case under this general head is the extreme sensitiveness of some persons to the approach of thunderstorms. The pathological condition experienced by such persons before a thunderstorm must not be confused with ordinary dread of thunder and lightning. In fact, this condition often comes on before there are any ordinary indications of the storm's approach, and the symptoms commonly subside before the storm is over. Attention was called to this condition some years ago by Dr. G. M. Beard, in Beard and Rockwell's "Medical and Surgical Electricity," and it was given the name of "astrophobia." Cases of its occurrence are, however, familiar to almost every body. The symptoms of the complaint seem to include all kinds of nervous manifestations, going on quite often to extreme nausea, and physical prostration.

One turns naturally to German literature for the elucidation of almost any scientific question that lies off the beaten track, but in this particular case without much satisfaction. It is true that W. Heilwich's unique book "Die neuartigen Erbschizophrenien" (Leipzig, 1911) gives quite an elaborate account of astrophobia (without calling it by name), but this work raises many more questions than it answers. Other German writers have dealt with astrophobia problems. For example, H. von Pfeiler has attempted to explain the physiological effects which felt before the arrival of the *Arctis* storm, as due to the rapid small fluctuations of the barometer.

Finally, in the *Festschrift für Schötenberg* for January 18th and February 1st last, there is a most suggestive article by Dr. Martin Finkler, of Dillingen, on "Wetterphobie." The author has been interviewing the sailors and pilots of the *Arctis* for a long time and writes: "However, these questions remain open. There is no explanation, apparently, here yet, even though we

Constructing the hull of the "Cope" submarine.

The completed craft. Note the forward propellers.

Astern at Long Beach Harbor, California.

The engine room showing the two 110 horse-power gasoline engines.

a depth of water of over 500 feet, and at that pressure run the engine for thirty minutes, always showing a vacuum of six inches on the engines. This test showed no appreciable leak on the engine."

The novel craft was built at a cost of about \$70,000, and was constructed partly by the Craig Ship Building Company at Long Beach, and completed in the yard of the Los Angeles Submarine Boat Company. In addition to its value as a war craft, Mr. Cope

# A New Way of Studying Astronomy

The Ingenious Celestial

Sphere Invented

By Prof. Wallace

W. Atwood

ON the evening of June 5th, in the museum of the Academy of Sciences in Lincoln Park, Chicago, a large celestial sphere was opened for inspection.

This huge sphere is so constructed that an audience of about fifteen people may enter at one time. After the audience has entered, the door is closed and in a few moments as the eyes become accustomed to the darkness the representation of the stars becomes evident. Little by little, more and more of the familiar stars may be seen until the effect is of a beautiful starlight night.

The instructor on the evening of June 5th was Wallace W. Atwood, the inventor of this apparatus. He used a long black rod tipped with a tiny electric light in the end and pointed out for the convenience of the audience all of the brighter stars and commonly known constellations that were at that time above the horizon.

Then, without anyone realizing it, Prof. Atwood touched an electric switch and caused the sphere to rotate. Other constellations began to appear at the east, pass overhead and set in the west, following paths precisely similar to those followed by the real stars in the real sky.

Soon someone observed that the moon was shining and slowly passing to the westward, and that at the appropriate time and at the appropriate place in the eastern horizon the sun appeared. The sun is represented by a small electric light that so illuminates the interior of the sphere that the stars are no longer seen.

The Chicago Academy of Sciences has appreciated the increasing interest in astronomy, and the difficulty which every one meets in trying to become familiar with even the brighter stars and more commonly known constellations. Various plans for promoting this study were considered by the Academy. The fact that stars are confusing to the untrained observer, and the globe, on the outside of which stars are sometimes represented, are unsatisfactory.

Through the use of the Atwood celestial sphere, it is possible to become familiar with all the constellations that are visible in the latitude of Chicago. Few people have had the opportunity of seeing all of these constellations, for on a given evening it is possible to see but a few of them and the apparent motion is so slow that it would take hours and hours of careful watching to see all of these visible on a single perfectly clear night.

The stars of the first, second, third, fourth and a selected number of those of the fifth magnitude visible from the latitude of Chicago are represented in the sphere, and the total number is 822. In addition to the fixed stars, four planets, Venus, Mars, Jupiter and Saturn, are represented, as well as the sun and the moon. The celestial equator is clearly marked in the interior of the sphere, and the ecliptic, or apparent yearly path of the sun among the stars, is also shown.

Many of the mathematical conceptions necessary for the study of descriptive astronomy, which often discourage the beginner, are made, with this sphere, perfectly simple. There is no reason why any child, including the youngest school children, cannot be made acquainted with the celestial sphere, their apparent positions, the brighter stars, and the real and apparent movements of our sun, moon, and planets.

Side view of celestial sphere from the west, showing the entrance.

A flashlight of the instructor pointing out the constellations and stars to small children.

North-south cross section of sphere.

1. South Polar ring at entrance. 2. Upper wheel supporting sphere. 3. One of two lower wheels which support the sphere and are provided by motor. 4. The electric motor. 5. North Pole of the horizon. 6. The sun. 7. Observer's platform. 8. North board. 9. The ecliptic. 10. The ecliptic of the sun's apparent path.

Many of the fundamental ideas in mathematical geography necessary in elementary education are also easily demonstrated with the sphere.

The Atwood sphere was in the Academy building was constructed, installed and presented to the Academy by Mr. LaVerne W. Noyes, president of the Board of Trustees, in order to broaden and promote the educational and scientific work of the Academy.

## Construction of the Sphere.

The material used in constructing the sphere is very light galvanized sheet iron, 1/64 of an inch thick, which has been pressed to the proper curvature and soldered to the equatorial ring and to a much smaller ring about the entrance to the sphere. The separate sheets lap sufficiently to be soldered upon one another. The platform and horizon table are of wood and rest upon a very strong steel frame.

The diameter of the sphere is fifteen feet. The weight, exclusive of the platform is a little more than 500 pounds. This weight is carried by a 2 1/2 inch tube attached to the outside of the sphere along the line of the equator and ending upon three wheels as shown in the cross section view. The two lower wheels carry the greater portion of the weight, but the third and upper wheel above the door rests a certain thrust, due to the inclined position of the sphere. The stationary platform within the sphere is supported in part by steel trusses resting upon the framework of the museum balcony and in part by two upright pillars which rest upon the great I beam of the main floor of the museum. This platform carries a circular horizon table below which the sphere is observed from view, and above which there is a complete hemi sphere on which the stars are represented.

The observer in this sphere is located on the surface of the earth at north latitude 41 degrees 20 minutes. Celestial spheres constructed for facilities having other latitudes north or south would be placed at other angles and certain other constellations would be represented. Thus a celestial sphere constructed for Buenos Aires to represent the southern heavens, would be so placed that the observer would enter from the north polar region and see the southern constellations, not visible at Chicago; observe the courses of sun and moon north of him, but fail to see any of the constellations about the North Pole of the heavens as seen from the latitude of Chicago.

Attached to the steel structure supporting the sphere is a small electric motor which propels the two lower wheels supporting the sphere and their rotation causes the sphere to rotate.

The electric power for rotating the sphere and the light for illuminating the interior are controlled from within the sphere. The electric current necessary for representing the sun is received at the North Pole at a rotary contact, and carried by the insulated wire from the ecliptic, about which there is a wire on the inside of the sphere.

## How the Stars, Planets, Sun and Moon are Represented.

The stars are represented by tiny perforations in the sphere. Different sized perforations have been made to represent stars of different magnitudes. The size

and location of each star in the sphere have been determined with great care by means of an instrument especially designed for this purpose, so that the sphere is an accurate miniature representation of the heavens. The shifting positions of the planets Jupiter, Saturn, Mars and Venus among the constellations have been provided for by a number of openings made to represent the different positions of each of these planets at different times of the year. The openings not in use are very readily covered.

The sun is represented by a small electric light which may be moved from place to place along the ecliptic and thus be kept in its appropriate place among the stars. The moon will be represented by a series of small disks cut to represent its various phases and equipped with a luminous salt. These disks may be moved from point to point along the orbit of the moon and thus represent that body in its appropriate position in the heavens.

### Record Journeys by Aeroplane and Airship

**T**HE cable and wireless had week flashed to America the news of two record trips by lighter-than-air and heavier-than-air craft respectively, that illustrate how far behind the old world the new world is in the matter of aerial navigation.

The first noteworthy flight, which preceded the other by one day, was made on June 6th by the latest Zeppelin airship "Raechen" from Baden-Baden to Vienna—a distance of 435 miles—in 16 hours and at an average speed of 64.1 miles an hour. This huge air-craft, which is fitted with three motors each of 145 horsepower, carried 24 persons on a visit to Emperor Francis Joseph of Austria. Three years ago Count von Zeppelin attempted to visit the Emperor by airship on the occasion of his 80th birthday, but without success. This time, however, he made a perfect flight. Piloting the airship himself, he left Baden-Baden at 8 A. M. and arrived at Vienna at 11—about half the time required by express trains for the journey. Four hundred soldiers assisted at the landing of the huge rigid dirigible on the Aspern Fields. Two hours later a terrific storm swept the parade ground, but fortunately the giant craft was so securely moored that she lived through it without mishap. The next day, in stormy weather, she made her way back to Friedrichshafen safely. The "Raechen" is the seventeenth Zeppelin airship. She is now to be stationed at Leipzig, while twenty more are being constructed in addition to the two at present in service.

The greatest achievement and longest flight of a heavier-than-air machine was that of the brilliant French aviator, Bremon, who on May 29th, 1910, covered close to 1,000 miles in 14 1/2 hours against time under terrific weather conditions. He used the same monoplane with which he flew from Bremen to London recently. It is fitted with but an 80-horsepower Gnome motor and made remarkable speed for its power, doubtless on account of a favorable wind.

Starting from Villacoublay at 8:55 A. M. de Moutillais made a non-stop flight of some 4 1/2 hours' duration. He landed at Wanne, in Westphalia, in the tenth of a 50-mile gale, and after a stop of 35 minutes resumed his flight to Berlin. He arrived at the Johannisthal aerodrome at 12:04 P. M. (11:04 Paris time), having covered the 575 miles from Paris to Berlin in 6 hours and 34 minutes flying time, or at an average speed of 90 miles an hour. When this daring aviator arrived, there was such a storm that some of the local aviators had risk making flights.

After a 3 1/2-hour rest, although the gale did not decrease, M. Brindejonc for the second time resumed his flight, traveling with the wind toward Warsaw. He covered the 150 miles in 3 hours and 15 minutes, or at the rate of 112 miles an hour. He left Berlin at 3:37 P. M. and arrived at Warsaw—309 miles distant—at 7:15, requiring but 3 hours and 38 minutes for the non-stop flight and averaging 97 1/2 miles an hour. The total distance of 685 miles had been covered in 10 hours and 12 minutes flying time at an average speed of 61 1/2 miles an hour as against 27 hours required by the Nord express for the journey. Even the clapped time was practically one half that of the railroad schedule, while the time in flight from Paris to Berlin was little more than a third of the time required by rail, which is 18 hours.

### French Prize Competition in Aviation

**T**HE United States Consul at Sidney, New South Wales, referring to the competition to be held in France for \$100,000 in prizes for the greatest inventions shown in progress in time in aviation, avows an entry will be made from Cape Breton by a French aviator, M. Henry, New South Wales. This invention is a parachute folded in a horizontal position on the tail of a flying machine and harnessed to the aviator and kept folded until strap connection to electrically released release, when the pressure of a button opens it, lifting the aviator out of his seat, so the parachute will come, as ex-

pressed by the inventor, the life buoy of the aviator. It is stated that a preliminary test of the invention will shortly be made at the laboratory of Prof. Graham Bell at Haddo, New South Wales.

### The Tree Sandalwood of India

**I**N the most ancient times the demand for the well-known sandalwood was very great as an incense for the idols. Its use dates back for more than 2,000 years, and all the records bespeak its rarity and costliness, in fact it always was priced more highly than any other wood. But with the advance of civilization new uses and applications opened up by scientific research, at once increased its consumption many fold. This is chiefly for carving and for manufacture of perfumery and medicine. It is obvious that wood with such a wide range of uses is in danger of being exhausted. As in the old days, so now, it is rare and on account of its scarcity very costly. And, unfortunately, sandalwood is rapidly becoming scarcer and more expensive, and the question is asked, How is the production and supply to be maintained proportionately to the demand? The importance of the question is shown by the efforts that are being made in India to cultivate this tree. It is consumed to some extent in India for wood carving, and the demand for sandalwood of the production is imported into China, where it is highly esteemed as an incense. The Chinese readily paying from two to four times more for the Indian sandalwood than for the less valuable substitutes from the South Sea Islands. The Indian species fully developed the sandalwood tree is a small tree, the bulk of the sandal oil of commerce is produced from it.

The sandal tree (*Santalum album*) is an evergreen, a member of the sandal tree family. The best known related plant in the United States is the bastard cedar (*Santalum spaldingii*). The native name of "sandal" wood was the old English name of it, probably derived from an East Indian name *o-sanda* or *sandana*, which is used very generally to indicate various kinds of so-called sandalwoods, and it is quite probable that the name is applied also to other aromatic woods.

The sandal tree is one of the small objects in the forests of India. Even in locations of its best development it attains dimensions that rarely exceeds 40 feet in height and varies from 8 to 12 inches in diameter, or sometimes as much as 18 inches. It is said to have been known to reach 22 inches in diameter at the base, but this can be the case only with very old trees growing in very favored locations. As a rule they are 8 to 10 inches in height and 8 to 12 inches in diameter when they are cut down.

The tree is a native of the mountainous districts of Southern India and is confined mainly to the dry regions. Its finest growth and development is reached in Mysore and Coimbatore, where the most silty and heavily silted wood is found between 2,000 and 3,000 feet elevation. While it is restricted to comparatively narrow limits the sandal tree has become naturalized in several countries, notably in certain districts in South Africa, where attempts have been made to plant it on a commercial scale.

It will endure a wide range of climatic and soil conditions, especially in protected places, but it will not respond to treatment like the majority of trees that are best for planters for revenue. The tree grows best in red or black loam or in fine gravelly soil with free drainage, especially where the soil is rocky. For the production of a large proportion of heartwood which yields the oil, the sandalwood tree must be grown under the most favorable conditions. This does not necessarily mean that the tree must occur chiefly in light deciduous forests. Flat ground and gentle slopes are preferred and the greatest bulk and height are attained with a moderate heavy rainfall. Rich soil is required for rapid growth, but this does not necessarily add to the oil content of the wood. For most of the uses other than the commercial distillation of the oil, the tree may well be cultivated wherever it can be made to live.

The importance of its cultivation may be urged, inasmuch as the great part of its use is from the roots and young branches, that have any heartwood developed. The chief commercial uses of sandalwood is for the extraction of sandal oil. The older, larger roots yield the greatest proportion of sandal oil. In India and Ceylon it is customary to dig up the trees by their roots and distill the oil from stump and root wood as well. The best oil comes almost exclusively from the root wood. The proportion of the valuable scented heartwood is only about one half of the log, while the sapwood has little or no value. Even the fragrant sapwood does not invariably add to the distilling value, and sells at the wood depot for from \$120 to \$160 per ton. Not all the sandalwood is employed for oil, but with its yellowish-brown color and susceptibility to a fine anti-life poison the wood is particularly adapted for the manufacture of incense, wood for carving, engraving, and for mirrors, chests, and drawers prod-

igious insects. The chief application for sandalwood in Europe came since 1870 for dyes. It is also employed for making beads, and for the manufacture of writing desks, walking sticks, picture frames, the handles, pen holders, card cases, trays, and when powdered is used to scent clothes. Large quantities of the wood are shipped to China for making incense for the rich.

The exploitation of a number of other closely related or even entirely unrelated species in the South Sea Islands, and in parts of Africa was undertaken, but it has now practically ceased. It is said that several species of *Myrsine* in East Africa will gradually supply the demand, but the wood is not only inferior to true sandalwood, but the production in any considerable quantities is doubtful. The export of the substitute sandalwoods from Australia is generally decreasing, while the supply from the Hawaiian Islands is entirely exhausted. That the production has ceased at the established sources of supply is not to be wondered at. Sandalwood cutting has been carried on in the most recklessly extravagant manner possible. In Hawaii and Australia the substitute sandalwoods trees have all been cut out, and in many parts of Australia the stumps of the trees felled fifteen to twenty years ago are now being dug up and shipped to the large markets in China.

In India attempts have been made for a number of years to keep up the supply by artificial stocking the forest, but the rate of planting has thus far been totally inadequate. Laws have been enacted to prevent the wanton destruction of the trees. Other causes besides extravagant cutting contributed to the decrease of sandalwood in India. Frequent hurricanes and stricted grazing destroyed enormous quantities of young trees, and after careful investigation it was determined that a government monopoly in Mysore in Southern India was the only means of saving the most costly of all the Indian woods. This caused the quotations at home and abroad to rise. A good deal of the wood now brought to the market is cut in hedge-rows and scrub jungles outside the areas marked as reserved forests. Since the monopoly is in force the sandalwood trade is more or less uniform from year to year, and the price of the wood is not so fluctuating as in the forest reserves will tend to keep the regular supply of the wood in the world's market.

### Ammonia as a Disinfectant

**R**ECENT experiments by Dr. Riegler of the Institute of Hygiene of Bonn-Wehr have the highly important result of proving that ordinary ammonia is a powerful disinfectant, even in the case of the most virulent bacteria. The experiments were conducted by *Bacteriologie*, the method of use was most simple, consisting merely in placing the ammonia in shallow vessels in the room, which was then, of course, hermetically sealed.

For a room containing 100 cubic millimeters of space 1 kilogramme of ordinary ammonia was used, with these results:

After 1 hour there had evaporated 20 gr of liquid	
" 2 " " " " " " " " " " " "	200 "
" 3 " " " " " " " " " " " "	300 "
" 4 " " " " " " " " " " " "	400 "
" 5 " " " " " " " " " " " "	500 "
" 6 " " " " " " " " " " " "	600 "
" 7 " " " " " " " " " " " "	700 "
" 8 " " " " " " " " " " " "	800 "

Examination of tissues previously impregnated with microbes showed that the bacilli of cholera and typhoid were killed by the ammonia in 24 hours, and the spores of anthrax in less than 8 hours, and diphtheria in 8 hours. The method is not only effective, but cheap, simple, and non-harmful to walls, pictures, carpets, and furnishings.

### The Current Supplement

**T**HE new page illustration of our current supplement shows a roller gaging machine specially designed for the rapid and accurate measurement and sorting of bearing rollers—F. V. Colville writes on "The Formation of Leaf Mold"—Prof. H. G. Cohen, in an illustrated article, describes the application of optical methods to the determination of structure in mechanical structures.—The history of the development of moving picture photography presents several points of interest, which, together with other points, are brought out in an article on "Kinetography Carried to Extremes"—A note, "How to Sell Artificial Silk," would be of interest to many readers.—W. E. Wood writes on "Double and Binary Stars"—An article of particular value is entitled "Sea and Air Quinman" discussing the Anglo-German war policy; England is re-asserting its fleet; and Germany sustains by building up a powerful air force.—A. E. K. and J. E. K. discuss the base and tendency of numerous natural processes to display a twist in a direction "Against the Sun."—A. G. Cohen writes on a new law of vulcanization.—F. E. K. discusses the probability of the existence of an ultra-terrestrial life.—The methods of soil chemical for investigating the problems.

Scott (on left) and companions in their fur sleeping bags.

Taking sample of sea water and temperature readings.

Cooking in the tent is surrounded under numerous difficulties.

Throwing the gang plank from the "Terra Nova" on "land," in this case thick ice.

Unloading the "Terra Nova." Carrying provisions to winter quarters on sledges.

The tent in which the explorers died. It stood up well in terrible blizzards.

Preparing to unpack the tent after a hard and a long pull.

#### To the South Pole With the Cinematograph Film Records of Scott's Ill-fated Expedition

[*LITTLE need be said in introducing to our readers the photographs reproduced with this article on Mr. Ponting's remarkable work as a member of the ill-fated Antarctic Expedition in which Capt. Scott and four of his fellow explorers lost their lives. The excellent views here shown, which, aside from their artistic and popular interest, are of no inconsiderable scientific value, are part of the Cinematograph picture film record now being exhibited in several of our large cities.—LONDON.*]

In all the centuries of polar exploration north and south the records have fallen markedly short of perfection in one essential element, owing to difficulties that until recently seemed never to be overcome. It is in the matter of illustration that the failure has been most apparent. Scientific observations have been complete, graphic accounts of adventure and valuable reports of conditions have appeared in the writings of explorers from the very first. But artists with pencil and brush have failed to carry conviction and realism to the mind of the people who stayed at home, and photography even has fallen far short of perfection. The flat pictures of snow expanses and posed portraits of fur-clad explorers with dog sledges brought home by some of the most distinguished of explorers have been hardly more than commonplace, even though taken under the most trying of conditions. In real value, pictorial or scientific, they have served but little better than the quaint engravings of conventional toilers and survivors of a hundred years ago.

It is in breaking this unvarying record that the British Antarctic expedition, under the command of Capt. Scott, achieved not the least of its noteworthy successes. That expedition from the beginning kept scientific objects ever in mind, and Capt. Scott organized a staff of specialists in every branch of natural science that could properly be expected to find material in the Antarctic. Furthermore, it was recognized that photography might well play a more important part than ever before, and for this reason there was attached to Capt. Scott's staff one of the most distinguished photographers and cinematograph operators in the world, Herbert G. Ponting, Fellow of the Royal Geographical Society, himself an explorer in many lands. Mr. Ponting approached his unique commission with a serious mind. He assembled equipment of photographic apparatus of a variety and perfection to meet every trying condition that could fairly be expected to develop in the Antarctic. He anticipated and organized for the difficulties to be met, and sailed northward toward the unknown with what was practically a new commission from science.

The result has proved the wisdom of the original plan and the excellence of Mr. Ponting's preparations. Literally thousands of negatives were made from the fall of 1910, when the expedition sailed south from New Zealand until the time when it ultimately merged with

A seal preparing to slip from an ice block into the sea.

A Weddell seal mother and her young. The skin of this seal has no commercial value.

Penguin hatching egg on a nest of stones. Both male and female birds sit on the egg.

One of the Siberian ponies in active antarctic transport service.

Watching under a screen an experiment to see how much snow melts.

What the men brought up from the sea: sponges, starfishes, etc.

A square-shaped sail spread to assist in drawing a snow-sledge.

Dr. Wilson with one of the fourteen Siberian ponies.

Two of the team of Siberian dogs that were always reliable.

Seal in the act of scooping steps in the ice with his teeth.

Snow-gull with its chick, which it will furiously defend.

Penguins huddle their wings which are formed like the wings of insects.

the news of the disaster to the polar party last February. Besides the individual photographic negatives Mr. Ponting brought back with him over 25,000 feet of film, and important selections from these are now being shown by cinematograph in several American and European cities.

In spite of the difficulties that beset Mr. Ponting in this undertaking the results, photographically speaking are worthy of being ranked with the best that have ever been shown with the cinematograph.

The difficulties began almost from the moment of starting. In order to photograph the actual progress of the bow of the "Terra Nova" in forcing its way through the ice pack in the Antarctic Ocean, a staging built from two planks lashed to the deck and the rail was extended far out over the side of the ship, and partly resting on this and partly suspended by rope from above Mr. Ponting squatted on his face and turned the crank of the cinematograph, while some of his most successful exposures were made.

Preliminary to arranging for the display of these pictures, Mr. Ponting made a recent visit to the United States, and had many interesting things to tell of the conditions under which he had worked.

"Difficulties?" said he, in telling his adventures shortly after reaching this country. "Of course there were many of them. Compared with polar photography, everything is easy. It is not only the difficulty of the light. That is soon mastered. The temperature is where the real trouble comes from. If you take off your glove and put your naked hand near the lens, instantly the lens is covered with a film of ice that no mere rubbing will remove.

Sometimes moisture, condensing into the finest particles of ice, will get inside the lens—then you are through. A grave danger averted the camera is the brass knob. If by accident, you touch with your bare hand any part of the brass of the apparatus, it will burn you just like a red-hot iron. On one occasion I was focusing under my cloth when I happened to moisten my lips. The point of my tongue came in contact with the metal and instantly from there, the shock was so great that I went over backward, and when I recovered I found that I had lost the tip of my tongue, which remained frozen to the camera.

"I recall one instance when I thought every moment was my last on this earth (or rather on Antarctic sea-ice). None of us were familiar with the ferocious killer whales, and so when we sighted a large school of them after seals, I dismounted and hastened over the ice to film the thrilling scene. Imagine my amusement when they gave up their chase after the seals and attacked me. Over a dozen of them forced into line, and diving under the ice, heaved their backs against the ice, breaking it up for hundreds of yards, and it was all that I could do, with the assistance of my comrades, to retain the safety of firm ice again with a school of vicious whales exerting their every effort to get me into the fright waters.

(Continued on page 563.)

View of the end of a sledge with a cyclometer attached.

Mr. Ponting among the penguins, and at a very close range.

One of the motor sledges hauling a number of trailers with supplies.

Climbing an overhanging glacier of peculiar form. A perilous feat.

A flock of penguins. These birds are unable to fly with their clumsy wings.

**THE** Imperator which is the newest of the liners built to ply the waters between the United States and Europe is also the greatest. She is almost one fifth of a mile long—to be exact, 818 feet. Her beam is 98 feet which compares favorably with that of a pretentious city street and her tonnage is 80,000.

No less remarkable is her machinery. The Imperator is driven by quadruple turbine engines developing 62,000 horse-power which drive the ship at an average speed of 23½ knots. The reversing turbines develop about 35,000 horse-power. There are four propellers measuring more than 164 feet in diameter and revolving at a normal speed of 156 revolutions a minute.

Since mere figures tell but little perhaps the real size of the Imperator may be best judged by her accommodations. For example no less than five great anchors are carried of which the main anchor, the largest in the world, weighs 26,425 pounds. The combined weight of the five anchors and their chains is 485,082 pounds. The cargo of mail, a small steamer is not much larger.

Some idea of the size of the Imperator may also be gained from the fact that her side is built upon 327 steel ribs, on either side each weighing a ton and a third. The weight of the steel plates angles profiles and the like totals 360 tons. More than 2,000,000 steel rivets were used weighing eleven pounds. No wonder that the tonnage of the Imperator is fifty thousand.

Because of her great size her decks are particularly imposing. Two of her three broad decks are partially enclosed. The promenades vary in width from 16 to 24 feet, while the circuit of the deck is equal to a walk of about five ordinary city streets. None of the ventilating funnels common to many steamers are to be found on the Imperator. Hence her entire upper or sun deck can be used for games and for promenading.

That the Imperator is in truth huge is driven home by the quantity of provisions carried. For a seven day voyage between New York and Hamburg the Imperator takes on board 25 tons of fresh meat, 48,000 eggs and 80 tons of potatoes. The larder besides contains 14 tons of fresh vegetables and 6,000 tins of canned vegetables. Besides there are over five tons of fowl and game and 4½ tons of fish and shell fish. 800 pounds of mushrooms and 4,000 cans of preserved fruits. No less than 1,500 quarts of milk and cream, 400 pounds of cheese, 500 pounds of chocolate and cocoa and 7,000 pounds of coffee are also taken on board.

A more comfortable or more luxuriously equipped craft than the Imperator it would be difficult to imagine. The passengers have a great choice of dining rooms ballrooms winter gardens, palm rooms grill rooms smoking rooms gymnasiums, roof gardens, and lounges. There is a precision stage for theatrical performances a running track an elaborate Roman bath and swimming pool a florist's shop, a candy shop a

photographic dark room electric elevators and other features not found on most transatlantic steamers.

The furnishings of the Imperator too are remarkable. The leading decorators of Europe have been given carte blanche. Thus the main lounge, which may be converted into a ballroom is hung with Gobelin tapestries. The sumptuous Roman bath reproduces with great fidelity the famous Pompeian Hall in the Louvre. The pool which is surrounded by decorative Pompeian pillars measures twenty-one by thirty-nine feet.

The provisions for safeguarding passengers on this largest of ships will naturally arouse interest. As we have already pointed out in these columns, the Imperator is built with an inner skin and with both longitudinal and transverse bulkheads. All told there are no less than sixteen steel bulkheads forming in all thirty-six watertight compartments. Further subdivision is secured by steel decks. The bulkheads have been carried to the level of the second deck high above the water line. That they will perform the function for which they are designed has been proven by actual test for the compartments have been completely flooded to ascertain their efficiency under extreme conditions. The compartments are hydraulically closed from the commander's bridge. Auxiliary controls are to be found on the upper deck.

Eighty-three large lifeboats are provided—sufficient to accommodate 2,496 passengers and a crew of 1,190. Two of these are motorboats, high powered enough to tow the others and equipped with wireless telegraphy.

The main staircase of the "Imperator."

The smoking-room has a large tastefully decorated fireplace.

apparatus having a range of over two hundred miles. Besides the usual life-bells, illuminated life-bells are provided.

The wireless equipment of the "Imperator" has a range of 1,000 nautical miles. There are two reserve antennas and two receiving instruments for long and short waves, designed for news service and rescue work. The station is manned by three expert operators one of whom is constantly on duty. So powerful is the wireless equipment that the vessel will always be within an easterly halting distance of land.

# An International Commission on Agricultural Meteorology

THE International Meteorological Committee recently appointed a commission on agricultural meteorology comprising the following members: M. A. Angot, director of the meteorological service of

the agricultural conditions of these plots unchanged from year to year in order that the exact effect of the varying weather conditions may be ascertained. The most important practical object in view is to gain accurately the agricultural climate of every part of the empire in order to guide cultivators in the choice of crops and varieties and in timing their operations. The bureau has issued a large number of publications of general interest but nearly all unfortunately in the Russian language.

M. Dop is personally identified with the agitation now in progress in Europe in behalf of improving the organization of meteorological work as applied to agriculture. He recently prepared an elaborate report on the present status of such work throughout the world which was published by the International Institute of Agriculture.

The new commission held sessions last September and

There is a feeling among agriculturists throughout the world that they are not getting the full benefit of the elaborate organizations for weather observation and prediction that exist in all of the civilized countries. In this respect, however, the American farmer is much better provided for than is his brother of the Old World. We already have an adequate meteorological service and the development of agricultural meteorology rests rather with the agriculturist than with the meteorologist.

## Preservation of Wood

EPINOY utilizes the property of the alkaline chromates to render gums and gelatins insoluble when exposed to the light. For this purpose the wood is immersed until complete saturation in a solution containing 2 per cent dichromate of potash and 1 per cent fluo-ur of sodium. After drying the wood is proof

The "Imperator" carries eighty three large life-bells, two of which are motor bells equipped with wireless having a range of two hundred miles. Note the manner in which the life-bells are carried.

Staircase leading to the Pompeian hall, a sumptuous Roman bath reproduced from the Pompeian Hall in the Louvre.

The swimming pool is sixty five feet long and forty-one feet in width.

Concert stage in the grand salon of the "Imperator"

France Dr. Richard Börschtein, professor at the agricultural high school at Wilmsdorf near Berlin and organizer of the public weather service of Prussia; Prof. P. Brunnov, director of the meteorological bureau attached to the Russian Ministry of Agriculture; M. Louis Dop, vice-president of the International Institute of Agriculture; and Prof. L. Palasio, director of the meteorological service of Italy.

From an agricultural point of view the most interesting person in this group is Prof. Brunnov as the bureau which he has directed since its organization in 1897 is the most elaborate agricultural-meteorological institution in the world. It comprises about one hundred and fifty special stations scattered over the Russian Empire at which meteorological observations are made in connection with observations on the growth of plants, the yield of crops, the state of the soil, the growth of insects, etc. An effort is made to keep

draw up recommendations. Some of the things room secured are: Improved methods of measuring the duration of sunshine and the intensity of radiation from sun and sky; more detailed study of fog dew and hoar frost; better methods of measuring the temperature of the air at various levels among and above growing plants; the study of optical phenomena useful in making local weather predictions; changes in the methods of publishing meteorological observations in order to serve the practical needs of agriculture; publication of daily weather maps at several distributing centers throughout each country (it is the plan now followed in the United States and latterly in Germany but not elsewhere); an evening weather service where this does not already exist and the rapid dissemination of weather forecasts and warnings in the rural districts (after the example set by the United States Weather Bureau).

against rotting. The wood is then painted with a solution containing 3 per cent dichromate of potash, 0.4 per cent fluo-ur of sodium and 5 per cent of gelatin, and is exposed to the light after drying the wood will be covered with a very strong brilliant varnish, and assume a brown color like aged wood.

Government Armor Plant—A bill has recently been introduced in Congress by Senator Ashurst of Arizona, appropriating \$1,000,000 for the construction of a Government plant for the manufacture of armor plates. The author of the bill believes that if Government-built armor were used in the battleship Pennsylvania it would save \$1,000,000. Secretary Daniels estimates that an armor plant would cost approximately \$1,000,000 but Mr. Ashurst has called for a few appropriations based on estimates made by a Senate committee in 1899.

#### The Loud-speaking Telephone

In the development of loud speaking telephones for announcing, two problems are presented—one that of obtaining sufficient volume and the other that of obtaining clear articulation. From time to time during the past few years, a number of so-called loud-speaking telephones have been developed and placed upon the market. These have either been loud and lacking in clear articulation, or clear in their articulation and lacking in volume. Thus failing to strike the desirable medium of clear articulation and sufficient volume.

The question of volume itself necessitates two lines of study, one to obtain that design of apparatus which will permit the largest current being used without injuring the apparatus, and the other that of obtaining the greatest efficiency from the available energy.

In the transmitter, the amount of current which can be used is limited by the mechanical dimensions of the instrument and the means which may be available for keeping the instrument properly cooled. If, however, the mechanical dimensions are too great, particularly those of the moving parts, the articulation is seriously affected. Accordingly, the amount of current which can be used is also limited.

The quality and articulation are largely dependent upon the mechanical dimensions of the diaphragm and the manner in which it is mounted. In any diaphragm a certain tone will be found which is fundamental to it, and as the weight of the moving part which is attached to the diaphragm is increased, this tone becomes emphasized. If the moving mass is not kept exceedingly small, this tone interferes with the proper reproduction of the words transmitted.

The problem of designing an efficient transmitter for this service has, therefore, been that of making use of the largest possible mechanical proportions in order to permit of large currents, without making the moving parts too great in mass to destroy distinctness of articulation.

The one particular point followed in the design of the loud speaking apparatus has been the obtaining of a method of construction which will give greater emphasis to the harmonics of the voice and less to the fundamental note. In general, this method will give far better results as far as intelligibility is concerned. This principle has been followed out consistently in the construction of both the transmitter and receiver used in the loud-speaking combination.

As in the case of the transmitter, the articulation of the receiver is governed largely by the mechanical characteristics of the diaphragm and the method in which it is mounted. In the receiver, the diaphragm has been corrugated and mounted on rubber cushions along the lines of rhombic construction. It was, however, found advisable to depart from one of the usual features of receiver construction and use a metal other than iron in the construction of the diaphragm. This was made possible by the use of an iron armature which would be acted upon by the pole pieces. Phosphor bronze was found to produce the best result from the standpoint of both volume and articulation and has, therefore, been used for the diaphragm. A lever arm connects the diaphragm to the armature.

By employing the magnetic principle used in the construction of polarized rings, the efficiency of articulation was found to be still further increased. This fact may be accounted for by the resultant reduction in the inertia of the moving

parts. The use of a differential magnetic circuit in the receiver has also made it possible to obtain a two-way positive action of the diaphragm. In the normal condition of the receiver the diaphragm is practically free from all tension. This has the effect of greatly increasing the efficiency of construction, due to the fact that a much smaller air gap may be used. These new and entirely original constructive features have produced a loud-

originated in a sound-proof glass-enclosed booth in the basement of the Grand Hotel. In this booth the special transmitters were located, as well as an ordinary telephone set connected to the lines of the New England Telephone and Telegraph Company. The installation of the telephones was made to demonstrate their use as announcements—to announce interesting events about to take place, to page visitors to the show, and to furnish music

from or to meetings by means of these instruments.

#### Blasting With Liquid Air

By Our Berlin Correspondent

THE first attempts to use liquid air as an explosive were made at an early stage of the liquid air industry in fact, shortly after the invention of its process. Prof. von Linde (in 1897), by mixing liquid air with charcoal, succeeded in producing an explosive which he termed "oxyliquita." This "oxyliquita" explosive was introduced directly into the blast hole and ignited by means of cartridges and fuses. As, however, this primitive process failed to give any satisfactory results, the explosive mass was filled into carefully prepared paper cylinders (commonly immersed entirely into liquid air), which were then introduced into the blast hole. Though sufficient explosive effects were thus obtained in most cases, this process did not warrant anything like the real safety and depended in an extraordinary degree on the skill of the men and the rapidity of working.

These unsatisfactory results are due on one hand to the physical properties of liquid air itself and on the other to the imperfect process used in preparing the explosive. Liquid air at ordinary atmospheric pressure, i. e., in the open air, contains a maximum amount of 181 cent. Cent. (—111.5 deg. Fahr.) and liquid oxygen a temperature of —183 deg. Cent. (—308.6 deg. Fahr.), the temperature difference as compared with the surrounding rock thus being about 200 deg. Cent. (360 deg. Fahr.) It will thus be readily understood that a lively exchange of temperature by heat conduction and radiation should be set up between the explosive and its surroundings, the liquid air in the blast hole being vaporized most rapidly by the absorbed heat. In fact, the explosive cartridges used in connection with these early experiments were found to become a maximum mass of 10 minutes at the outside, their efficiency being considerably reduced even after a shorter life.

After being discontinued for many years, these experiments were recently taken up again by a German mining engineer, Mr. Kowatsch, who in conjunction with Mr. Reineke of Charlottenburg, was allowed to work at the Royal Quarries of Riddensdorf, near Berlin. In accordance with the above, Mr. Kowatsch tried to prevent the liquid air in the blast hole from evaporating by any possibility beyond a given limit. He therefore conceived the idea of introducing the cartridge with the dry carbon holder separately into the blast hole without the liquid air, and afterward making any mixing preparations (tamping the blast hole, etc.), waiting until the very last moment to add the liquid air and igniting the mixture immediately afterwards. This process obviously allows the time of vaporization to be reduced to a minimum, thus saving much of the liquid air otherwise required, cheapening the process and warranting an incomparably higher safety.

A substantial pasteboard cylinder containing a perforated distribution tube and fitted with an absolutely inert substance of kieselguhr and oil, asphalt, gut, or paraffin, is introduced into the blast hole; then, the central distribution tube is introduced in this empty tube (of paper) over which another paper tube for discharging any products of vaporization of the liquid air is slipped, after which a cartridge may be safely proceeded with. When the empty blast hole has been thus prepared, namely, the essential components are properly connected with one another and when the blasting mixture

Announcing the score at a baseball game by means of loud-speaking telephones.

speaking telephone which combines clear articulation with a maximum of sound volume.

The first public appearance of the loud speaking telephones was at the Boston Electrical Show, held in Mechanics Hall, during September and October, 1910. Ninety of these show-boards were installed in various parts of the hall and divided, for convenience, into groups of ten, making nine separate circuits, which were

from a photograph in the transmitting booth. Another use to which they were put was to announce the losing-by lining scores of the World's Series baseball games then taking place. That the telephone produced practical results was evidenced by the fact that a child which had been separated from its parents in the throng was found through its agency; and it was no unusual thing for exhibition officials to be summoned to their of-

# Price Maintenance and Modern Merchandising—I

## Price Fixing by a Monopoly and Price Fixing by a Single Manufacturer

### By Waldemar Kaempfert

THIS is the first of a series of short articles intended to set forth in a simple way the economic necessity of fixing and maintaining the retail price on certain kinds of manufactured products. Merchandising articles, the last twenty years—changed chiefly because nation-wide and world-wide selling has been made possible by advertising in this remarkable development of business economic discoveries have been made which are not yet widely known. It is the purpose of these articles to set forth those discoveries so far as they affect price maintenance.—[Burros.]

A single term is often used to designate two different acts or things, the one good and the other bad, with the result that it is sometimes difficult to distinguish them. Politician has acquired a very sinister meaning in the United States yet in England a politician is a very respectable member of the community. So the words price maintenance—fixed prices, and their equivalents have come to mean, popularly trust control, whereas business men employ them also to designate a form of control that is far removed from monopoly domination and that in its reality a healthy stimulus to competition.

Between an agreement of twenty refineries to sell sugar only at 10 cents a pound and the policy of a hundred refineries to sell his trademarked or patented article at a uniform retail price there is a world of difference. The people must buy sugar at the price fixed by the combination of refineries, but they can control the raw material for there is no other source of supply. But the people need a thing of the trademarked or patented breakfast food of the single manufacturer or for there are a hundred other breakfast foods to be had if the price is too high. It is curious that the term price maintenance should connote both a reprehensible and a commendable business practice.

When a trust fixed prices before the Sherman law was effectively applied its chief consideration was public sentiment. The newspapers, the magazines, the editorialists and satirical cartoonists calculated to inflame the public mind. What legislators be stirred into activity? These considerations were more important than a study of market conditions. On the other hand the manufacturer who makes a particular brand of soap which he personally guarantees or a particular kind of watch to which he gives a name and reputation must study his market. First of all he must gauge the demand for his trademarked or patented product. Next he must ascertain what competition he is likely to encounter. The extent of his market and the number and character of his competitors very largely determine the price at which he can sell his product if he fixes his price too high he automatically cripples himself. He either limits his sales and thus his income or permits a rival to underbid him. While the trust that controls a necessity of life may fix its prices to suit their unscrupulous, a single manufacturer by the very force of competition will market his price so low that the public will be inclined to buy and that rivals will be unable to underbid at a substantial profit to themselves.

A single manufacturer must know the laws of supply and demand for a time a single manufacturer must obey them or fail. Pick up any popular magazine and glance through its advertising pages. You will find a half dozen more or less similar breakfast foods competing with one another several watchmakers setting forth the merits of their timepieces, at least some large manufacturers of men's clothes who proclaim the attraction of their tailored fabrics and several sportsmen manufacturers who lay stress on the mechanical excellence of their lawn mowers. You will find that there is not a very wide variation in the prices of competing wares of the same quality. Each manufacturer knows exactly that a retailer must make at least twenty to twenty five per cent profit on the advertised goods to do business at all and that the jobber who supplies the retailer must make at least fifteen to twenty per cent for the same reason. He knows that he himself is entitled to about ten or fifteen per cent. Very carefully he studies his manufacturing processes, his methods of buying material, his system of distribution—all for the purpose of assuring to the jobber and the retailer the profit to which they are justly entitled and of allowing himself a profit large enough to place his business on a firm basis yet small enough to elude coverage competition.

It is one thing to fix a price on a well known article of manufacture and another to maintain it. Before the Supreme Court handed down its decision in the *Fanstrom* case it was comparatively easy to maintain a price on a patented article. The law manufacturers have held that the exclusive right to vend his product given by law to the patentee meant the right to sell it at the price he wished. The right to a price cut as a patent infringer. Since the Sherman law did not apply to patents I warn the inventor stood in a very favorable position. But the *Fanstrom* decision destroyed him of his price fixing privilege and he is placed him on exactly the same footing as the vendor of unpatented staple products.

It matters little to a farmer whether the dealer to whom he sells his potatoes retails them at 10 cents or \$1.00 a bushel, but it matters a great deal to the patentee of a widely advertised watch whether his selling price is maintained or not. No one knows who played the potatoes that the corner grocery store, but everyone knows who made the patented watch that sells for \$50. The farmer spends a money in advertising, his potatoes or distinguishing them from those of his neighbor. He deals in a staple product. He who watches watchmaker spends perhaps a million dollars a year in coupling his name and his with his watch in guarantee, its workmanship in driving home its price. His good name and reputation eventually become his principal asset in business. They become a species of property of such value however intangible they be that they can actually be sold. If he loses his name and reputation either through his own carelessness or the trickery of others, he is in a poor way indeed.

Good will and reputation mean far more than their value in the past. In the days of a primitive world wide advertising a craftsman and his handiwork were known chiefly in his own community. A modern advertiser blazes his name and his wares in a thousand magazines and newspapers. Millions know him by reputation and if his reputation is good he must inevitably prosper. One way of robbing a manufacturer of his good name is to sell his goods at less than the price that he has established by much expensive advertising. If a fountain pen that is ordinarily sold at 85 with the minimum profit to the manufacturer and his distributor is advertised at 50 cents less than the cost of production by some department store the public naturally leaps to the conclusion that the manufacturer has been too grasping in a word that he is not to be trusted. Very few realize that widely advertised articles are thus sold at ridiculously low prices by department stores and mail order houses solely for the purpose of strutting custom, and that the loss thereby in price cutting is more than compensated for by an enormous profit on less well known goods.

This policy of trading on the reputation of a well advertised article not only injures the manufacturer but also the public. How that effect is produced will be explained in the next article of this series.

## PATENT ATTORNEYS

# PATENTS

If you have an invention which you wish to protect you can write fully and freely to me. I can tell you the best way of obtaining protection. Please and describe a model of your invention and a description of the same is required in my office.

All communications are strictly confidential. Our vast practice, extending over a period of more than thirty years enables us in every case to advise in regard to the expediency of any response to the client. Our Head Office on Patents is in New York City. We have branches in all the principal cities of the United States. TRADE MARKS FOREIGN PATENTS, etc. All patents secured through us are described without cost to the patentee in the SCIENTIFIC AMERICAN.

## Cutlery of Known Worth

Keen Kutter Safety Razors are made with a "hang" that insures comfort and satisfaction in shaving.

Keen Kutter blades are made of the finest cutlery steel, ground extremely thin, but thick enough to shave the thickest beard with ease. Don't experiment with razors of inferior quality, but safeguard yourself by asking for the kind marked

# KEEN KUTTER

Feel the edge of the Keen Kutter Pocket Knife. Its keen edge rings true. It holds its keen edge indefinitely. Like all articles bearing the name Keen Kutter, these knives are positively guaranteed to give entire satisfaction or money back.

\* The Recollection of Quality Remains Long After the Price Is Forgotten.  
Trade Mark Registered — U. S. PATENT OFFICE.

If not at your dealer's, write us.

## SIMMONS HARDWARE CO., Inc.

St. Louis, New York, Philadelphia, Toledo, Minneapolis, Sioux City, Wichita.

## An automobile, to give entire satisfaction, must be equipped with an entirely satisfactory electric starter and lighting outfit.

The engineers who design automobiles know this. They realized the demand for some kind of a starting device last season, as a result 1913 is a "self-starter year."

But because they could not foresee the public clamor for starters years ago and be-

cause the manufacturers of electrical devices could not foresee it, some engineers thought they were obliged to accept as "standard equipment" on the cars which they designed for 1913, starting and lighting systems which they themselves knew to be still undeveloped.

The Aplco system is not the hastily constructed kind

Vincent G. Apple designed an electric starting and lighting system in 1900, and it has been carefully developed in the intervening years. He might have put it on the market years ago, had he not determined never to allow any device to leave the plant with the name Aplco upon it until it was perfect in every detail.

The motor car builder's present preference for the Aplco system is not based upon expensive advertising. The selling price of Aplco devices is not made up of items of this nature. It is the materials—the very best to be had anywhere—the workmanship, the "know how," which accounts for Aplco quality and Aplco price.

Mr. Apple's long training in electrical work for motor cars and motor boats has enabled him to make economies in manufacture which his competitors have entirely overlooked, because they lacked that training.

His personal supervision of his corps of engineers has enabled them to work out his ideas and get for the automobile manufacturer and his patrons—the public, the benefit of these economies.

## The Aplco Starter

will be the preferred starter on 1914 cars. Here are some of the technical features that commend it to automobile engineers.

### The one-unit system

The one unit system used for the Aplco is the compact ever reliable system of the electric manufacturer who knows how to combine these perfectly natural units into one mechanism. The two-unit system can only be regarded by experienced engineers as a make-shift justified to its manufacturer because of cheaper construction because he has to rush on the market to meet the big demand.

### A 24-volt machine

The repeated tests and study on the starter question that have been going on in the Apple factories for ten years have convinced their corps of engineers that anything less than 24 volts will not give the best service. This added voltage gives additional power for starting purposes and through the controller returns the 6 volts for lighting, ignition and signaling. It gives its charging rate at low car speeds and eliminates too strong a pull on a small battery.

### The two wire cable plan

The Aplco systems are built on the two wire cable plan. The return copper cable system eliminates numerous ground lights. The one cable system makes almost impossible the dimming of lights which is one feature of the Aplco two wire plan, and the connecting of dash and tail lights in series so that the driver can determine from the seat whether or not the tail light is burning.

### "It never stops starting"

If you are getting ready to buy a 1914 car with the most reliable equipment you should not be satisfied with a so called 6 volt starter nor a one wire system. They have a lot to do with real service from a starting system.

We can help you to bring your present car up to date by installing the Aplco electric lighting system and Aplco lamps which penetrate dust and fog. If you don't know the Apple service station in your locality you should and we will tell you if you ask.

**The Apple Electric Co., 62 Canal St., Dayton, Ohio**

# Something New and Vastly Better

## MARK COLD DRAWN SHERARDIZED STEEL UNIONS

Drawn from Rolled Steel.  
Not a cast iron product.  
Then Sherardized to prevent corrosion.  
Leak-proof under ANY pressure.

Pat. App. for

A union that will not crack as cast unions do  
A union that has a perfect, leakless seat—denafied steel against soft brass

A union that is tapered to fit standard pipe taper so that all threads are in perfect mesh

Here at last is a pipe union that expands and contracts under alternate heat and cold the same as the pipe and will not stretch and assume a permanent "set" as malleable unions do

The Sherardizing process not only coats it with zinc but actually makes a zinc alloy of the steel. This Sherardizing is done, after threading, thus protecting the threads from rust and corrosion

See full parts lists and prices in this new booklet: rustless high pressure pipe union

**MARK MANUFACTURING CO.**

1903 Dempster Street

EVANSTON, ILLINOIS

## GRAFLEX CAMERAS

No camera is so good as the Graflex for making pictures of children. Indeed for the whole household may be made full size pictures of every perfect picture.

For one photograph no dark slide when you use a Graflex. This picture was made on a rainy, heavily clouded day in December.

The Graflex is built for those who want to be certain.

On clear days, when the sun is shining the Graflex will give pictures in 1/1000th of a second.

The GRAFLEX makes better photography possible by eliminating the uncertainties. Focusing scale and "finder" are done away with. With a GRAFLEX you see the image full size of finished picture, up to the instant of exposure right side up. You know to a certainty that the picture is in focus, without having to guess the distance between the camera and subject

The GRAFLEX Focal Plane Shutter works at any speed from "time" to 1-1000th of a second.

## To the South Pole With the Cinematograph

(Continued from page 361)

Of all the scenes cinematographed in the Antarctic that Mount Erebus was the most difficult to secure. It would have been folly to drag the heavy apparatus up the volcano's side but by a stroke of good luck and through a special table-escape lens taken especially to record the volcano a beautiful clear film was obtained

Once when I was securing a film of a pair of young skua gulls in their nest at very close range I was attacked by the parents so furiously that I was almost laid out. One of the pair swooping down it me struck me such a blow in the eye with its wing that for an hour or two I suffered most acute pain and at last feared for the sight of my eye

On another occasion, when endeavoring to induce a seal weighing perhaps a half a ton to pose for a picture it was duly priced the most determined objection to the proceedings and hanging out at me it seized hold of my leg throwing me to the ground. Its back went through all of my clothes and the blood then was it hurt owing to the fact that I fell. Had I not done so, I think my leg would have been broken. This, I believe is the only instance on record of a Weddell seal ever having bitten a man alive. I certainly invited the trouble and I probably deserved what I got

The queer little penguin reminds one of a comical little gentleman dressed in immaculate white waistcoat with white turtleneck collar. These birds are unable to fly their wings being merely flappers. Their habits greatly resemble primitive man. In fact the little male selects his mate at certain periods of the year from among countless females who assemble on the hillside to be inspected by their future lords and masters. The little chicks wander on and around the adults fairly like a mob of overbearing fairies. No mean degree of intelligence and when they decide upon propounding the male salutes and picks up a stone which he brings and deposits at the feet of her ladyship, emblematic of his ability to provide a nest for their young. He ignores him for some time until finally he has jilted up quite a mound of stones and then quacks her approval and acceptance. If they go to establish a nest upon the hillside

It is unnecessary to point out the tremendous interest which is fastened by the cinematograph in such an expedition as that of Capt. Scott. Time was when the results of these perilous voyages of discovery were scarcely thought worthy the cost. Nowadays however when the pioneer way train the eyes of the world upon the windows which it is laying here for the first time by his efforts the risk is justified. He is not storing p experience for himself alone but for the whole of mankind. His success becomes a matter of paramount interest and importance to everybody because it is a success in whose benefits we can all now share

Mr. Poston when taxed with the question "Did you learn the art of photography in your native land?" replied "No I learned most of my photography in one of the finest countries on earth—California. I lived there ranching and sailing for about ten years, and there is practically no branch of photography that I have not studied in that land of perpetual sunshine and flowers. My work in South California attracted the attention of a big New York publishing house which made me an offer to travel around the world in their interests. This offer was felt well by others and since then (1900) I have been traveling and illustrating everywhere—in thirty different lands. These travels involved every possible kind of photographic work and in every conceivable climate. I have had to take photographs of mountains 70 miles distant, and to go to the edge of the earth, micro-photographs of almost invisible objects. I have watched in the twinkling of an eye the growth and growth of things and the phases of life, the growth of the plants

### The Modern Gasoline Automobile

ITS CONSTRUCTION, OPERATION, MAINTENANCE AND REPAIR.  
By VICTOR L. LEE, Vice, etc.  
The most complete and up-to-date book published on the subject of the modern gasoline automobile. It covers every detail of the car from the engine to the wheels, and is a must for every owner and mechanic. Price, \$1.50.

### Scientific American Reference Book

EDITED BY ALBERT A. HOPKINS  
Compiled by EDWARD ALBERT A. HOPKINS and others.  
A handy compact, reliable and up-to-date volume for every one who is interested in the latest scientific news. It contains the most important facts and figures of the year, and is a must for every library and office. Price, \$1.50.

### Wireless Telegraphy and Telephony Simply Explained

By ALBERT A. HOPKINS. 32 pp., 154 pages, 154 illustrations.  
A complete and up-to-date book on the subject of wireless telegraphy and telephony. It covers every detail of the system from the transmitter to the receiver, and is a must for every owner and operator. Price, \$1.50.

### The Scientific American Handbook of Travel

By ALBERT A. HOPKINS. 32 pp., 154 pages, 154 illustrations.  
A complete and up-to-date book on the subject of travel. It covers every detail of the system from the traveler to the destination, and is a must for every traveler. Price, \$1.50.

### The Scientific American Cyclopaedia of Formulas

Edited by ALBERT A. HOPKINS. 32 pp., 154 pages, 154 illustrations.  
A complete and up-to-date book on the subject of formulas. It covers every detail of the system from the formula to the application, and is a must for every scientist and engineer. Price, \$1.50.

### Concrete Pottery and Garden Furniture

By RALPH C. GARDEN. 32 pp., 154 pages, 154 illustrations.  
A complete and up-to-date book on the subject of concrete pottery and garden furniture. It covers every detail of the system from the material to the finished product, and is a must for every artist and craftsman. Price, \$1.50.

Any of these books can be had by mail from the publisher, Scientific American, 215 N. York St., New York, N. Y.

## The Voice of Reconstruction

When a flood sweeps over a vast area, desolating the cities and towns which lie in its course, the appeal for assistance gets a unanimous response from the whole country.

With all commercial and social order wiped out, an afflicted community is unable to do for itself. It must draw upon the resources of the nation of which it is a part.

In such an emergency, the telephone gives its greatest service when it

carries the voice of distress to the outside world, and the voice of the outside world back to those suffering.

At the most critical time, the nearest telephone connected and working in the Bell System affords instant communication with distant places.

And always the Bell System, with its extensive resources and reserve means, is able to restore its service promptly, and in facilitating the work of rebuilding, performs one of its highest civic functions.

PORTLAND CEMENT MAKING is described in excellent articles contained in Scientific American Supplement nos. 1432, 1465, 1466, 1510, 1511. Price 10 cents each. For sale by Munn & Co., Inc., and all newsdealers.

**Rent This Transit or Level for Nine Months —then it's yours**  
Engineers and Surveyors

**THE TRANSIT**  
This is the best instrument for the transit and level work. It is the only instrument of its kind that is so simple and so accurate. It is the only instrument that is so portable and so durable. It is the only instrument that is so cheap and so reliable. It is the only instrument that is so easy to use and so accurate. It is the only instrument that is so simple and so accurate. It is the only instrument that is so portable and so durable. It is the only instrument that is so cheap and so reliable. It is the only instrument that is so easy to use and so accurate.

### NEW BOOKS, ETC.

**THE PRINCIPLES OF EFFICIENCY** By Frank Kester. New York: The Sturgis & Walton Company, 1913. Price, 85 net.

Mr. Kester's book assumes rather a common attitude. "Thus, statements such as that which occurs on page 12, to the effect that 'no Catholic can become President of the United States, no Jew 90 athletic, no Southerner and no philosopher, however great, finds its counterpart in similar assertions. We have a Southerner now in the presidential chair. But apart from a tendency to overstate his case there can be no doubt that Mr. Kester has performed a really valuable service in pointing out wherein we are nationally inefficient, and wherein we may improve ourselves. A thorough knowledge of German conditions on which to present many an instructive contrast with corresponding American conditions naturally much to our own disadvantage. Mr. Kester is a distinctive rather than a constructive critic. He is better at picking out flaws in our social or political rather than at indicating how they may be corrected. A very large part of the book is quoted matter, but it comes from excellent sources and helps along his cause."

**THE PANAMA GUIDE** By John O. Collins, Mount Hope, Conn. 200 pp. Price, 1012

This is an excellent guide book written primarily for the tourist, but also of interest to the general reader who is making information a compact form on the Panama Canal and its construction.

**THE NEW HOUSEKEEPING EFFICIENCY** Studies in Home Management By Christine E. Frederick. Garden City and New York: Doubleday, Page & Co., 1913

Mrs. Frederick's book is a republishing of a series of articles that originally appeared in *Ladies Home Journal*. In it we find a very interesting study in applying to housekeeping the efficiency principles of Mr. Harrington Emerson and Mr. Frederick W. Taylor. The thoroughly practical character of Mrs. Frederick's book, the intelligence which she displays in presenting values of it in saving time and money, make her advice extremely helpful even to the most experienced housekeeper. Now that the requirements of the housekeeper are so high, it is not surprising that the architect to profit by Mr. Frederick's investigations for the work of all efficiency, whether it relates to a household or a manufactory, is a well-defined plan. Thus far the architect has provided a household plan which meets only the most obvious requirements—the stairs running water, drainage and electricity. What is now needed is a house designed according to efficiency principles as far as the internal economy is concerned. In that work Mrs. Frederick's book will prove of great help.

**LA MER** Paragraphs 21 to 25 Paris: La Librairie Larousse, 1913

In these ten installments of the excellent *La Mer* of Larousse we find popularly written yet accurate articles on everything handling a sailing ship, navigation, harbors and ports, the planning and administration of a port maritime, etc. As a view of port and illustrates the work of Larousse may be regarded as a model.

**WIRELESS TELEGRAPHY, WIRELESS TELEVISION, AND WIRELESS TELEPHONE IN POPULAR PRESENTATION** By A. Monier With a Preface by Prof. E. Branly. D. Dunod and P. Pichard. Paris: 1913. 242 pp. Price, 2 francs 50 centimes.

Wireless telegraphy owes a great deal to French scientific genius. We may fairly credit the author his patriotic pride which induces him to claim for France the chief story of the development of wireless telegraphy. Perhaps an impartial judge might be inclined to give chief credit to the man who Maxwell and Hertz. The fact remains that the first practical demonstration of wireless telegraphy was made in France, and that the French have made important contributions which they have made toward developing wireless telegraphy. The book is written in a simple and popular presentation of the main facts relating to the theory and practice of wireless telegraphy. Of particular interest are the chapters on telemechanics, that is to say the operation of various mechanical devices from a distance by the aid of electric waves. Very valuable too is the account of the wireless station installed upon the Kiffu shore. But the book is full of other interesting material. It is a table of contents, but no index, a slight defect which may be excused in the case of a new work, particularly as the table of contents is very complete.

**DE BLUMENHUTTEN** By Von Dr. Adolph Koenig. Stuttgart: Koenig, 1913

This is a well written popular account of fresh water flora. It is another desirable addition to the excellent literature and popularly written monographs issued by the Koenig books.

**WOMEN AS WORLD BUILDERS** Studies in Modern Feminism. By Floyd Dell. Chicago: Furber & Co., 1913. 120 pp. Price, 75 cents

In spite of the author's professions of discontent the motive and message he ascribes to the feminine movement are optimistic and constructive. The literature does not present the movement from such optimistic and human.

All pens may look alike, but expect inspection and wear show the real qualities. Esterbrook pens stand the test of constant use. 1000 repeating copies over half a century. A single pen costs nothing. Write for Esterbrook Pens. New York City. 85 John St. Esterbrook Pens

The Editor is always glad to receive for examination illustrated articles, and to return them with suggestions. The contributions will receive special attention. Accepted articles will be paid for at regular rates.

The purpose of this journal is to record accurately, simply, and interestingly, the world's progress in scientific knowledge and industrial achievement

## Horse Living Versus Horse Power

**T**HE SCIENTIFIC AMERICAN of January 19th has published an illustration of a horse-drawn truck. In the Electrical Engineering Department of the Massachusetts Institute of Technology showing how far horse, gasoline and electric trucks of different capacities could travel per dollar. The expenses of the trucks were represented in the form of loads dragged along the ground behind them. In each case the load was made up of four different items, one representing the charge for feed, fuel or electricity, another for maintenance, the third for the garage or stable including driver and helper, and the fourth for overhead charges.

Where the horse showed to the greatest disadvantage as compared with the motor, was in the cost of feed. Herein is the principal difference between animal and mechanical powers. The reason is that the horse is using his energy in the form of heat, while the vehicle is using its supply of energy only when performing work. To put it differently, the horse is paid (in feed) by the day, while the motor is paid by the job (in gasoline or electricity). Work with a horse is a product. Most of the energy fed it is expended in building up and maintaining its own bodily health. If a horse required no food during the day hours there would be little chance for the motor truck (except in special conditions). To be sure a working horse is fed more than an idle horse, but it does not necessarily follow that the extra feed will all be converted into useful work.

It is very important to know just what return the horse is giving for the feed it receives, because it costs fuel or fuel equivalent much more rapidly than the motor. On another page will be found an illustration based on figures furnished by the Massachusetts Institute of Technology showing how much work a horse does in an average working day, when engaged in the service of hauling freight from a railroad freight house to a delivery warehouse. This is not necessarily typical of all lines of transportation but it does show that the actual work done by a horse may be far less than one would suppose without study. As depicted in our illustration, the horse truck was working only 40 per cent of the working day, it was traveling between warehouse and freight house only 10 per cent of the day and during only 15 per cent of the day was there at least a partial load on the wagon. A working horse may be given as much as 30 per cent more work than an idle horse. In return for which it may be working only about an hour and a half out of a working day of ten hours, or only about 0 per cent of the entire twenty-four hours, during all of which time it is consuming fuel for its own maintenance.

As it is principally in fuel consumption that the motor truck shows its superiority over the horse truck, it is obvious that under conditions where actual work is done during only 15 per cent of the working day, the motor truck may show but little more efficiency than the horse truck. Obviously under such conditions the coach is to adjust the work so that the truck will keep moving practically all the time with full load. This can be accomplished only by using special loading and unloading devices. A common practice is to provide special bodies which may be loaded and unloaded at leisure without delaying the truck. Still another suggestion is to have the truck haul a half load on the truck with a minimum of delay. The motor truck will then be the equivalent of a locomotive. In fact, Mr. Morgan Olney, writing in a recent number of the *Engineering Record*, proved that in many situations a motor truck can be better than a horse truck, even when carrying the same load on its own wheels. The motor

vehicle is too valuable a machine to stand idle at any time during the working day. If the truck were used as a locomotive many problems of its construction would be eliminated. One of the principal difficulties met with in the ordinary truck lies in the provision of springs suitable for all conditions of use. If the truck were used for the month for the fully time, they will be stiff enough to break the mechanism when the vehicle is running empty.

It may be thought that various time-saving expedients can also be applied to the horse. While there is no doubt that a better return for the investment can be made by reducing the life time of the horse, it must be remembered also that it is when moving that the motor truck shows its chief superiority, and also that the horse cannot be kept working constantly all day long but requires many rest periods for recuperation.

## A Simple Parcel Post Wanted

**S**INCE the enactment of the Parcel Post law of August 24th, 1912, and its introduction on January 1st, this year much criticism has been made in the public press about the complications, restrictions and the expense of the Parcel Post law as specified in the law and a demand for a reduction of the number of zones, or instead, the establishment of a low flat rate with an increased weight limit, over the eleven-pound limit now in use.

As a result of a recent article in the *New York Sun* on "Parcel Post Defects" wherein it refers to the evidence given before the Post Office Department investigating committee as being of considerable interest, it goes on to say:

"When however responsible merchants declare in their evidence that their use of the parcel post has been reduced by nearly two thirds since its inception and that they have been compelled, however unwillingly, to give their business to the express companies it is obvious that something is seriously wrong."

The *Sun* refers to the complications in the handling of packages. In its instance half of the packages sent were recorded at their destination in a damaged (crushed) condition. It is also stated that in other countries where the system is in effect, damage to packages in transit is comparatively rare, and there appears no reason why a similar security should not be obtained here. The *Sun* concludes by saying that the investigating committee should advocate a return to the ordinary letter stamp.

Referring to the same system, the *Sun* continues:

"A more serious difficulty is the slow system which is required to collect and to record the rates. The difficulty would seem to justify the system as it appears on the face of it anomalous to carry a parcel a thousand miles for a rate which is charged for a shorter distance. The shippers who gave evidence on Tuesday were amazed in asking for a flat rate and in saying that the ideal system would be a bulk rate where shippers could drive a tray load of packages on the scales and pay at so much a pound or ton. If such a system were adopted it would probably be found to be practical that the shippers balanced the load. Certainly it would make for simplicity, and if the public is to become habituated to using parcel post to the extent it is said to be used to justify itself, simplicity in its regulations is a first consideration."

The act of 1912 provides for the change of rates and weight limits and the consideration of zones by the Postmaster General subject to the consent of the Interstate Commerce Commission when the cost of the service will not exceed the revenue therefrom.

If the plan mentioned above—"that the short freights balanced the long"—is true, and according to the law of revenue and cost should be, it follows that a uniform parcel rate applicable for individual localities as well as great distances should produce sufficient revenue to be self-sustaining.

With the introduction of perfected high-powered express vehicles capable of carrying large volumes of postal matter direct from one post office to another, over night, between cities a hundred miles apart, such economy of transportation cost would be effected, and the expense of doubling handling be saved.

A similar use of the automobile rural delivery post wagon, as proposed by the Postmaster General League, where a vehicle should start at each end of the route, on a given hour, in opposite directions and carry merchandise and passengers by the parcel post system. This would facilitate the exchange of farm produce along the route and provide facilities at low rates to the residents on the route for personal transportation.

Personal transportation has been in successful use in a few foreign countries for some time. A simplified parcel post based on flat rate, yet paying rates, will have a stimulating effect in the transportation of light commodities throughout the country, and encourage trading by mail to a greater degree than ever before.

## The Aeroplane in Way

**A**LTHOUGH aeroplanes were used on many occasions during the recent Turco-Italian campaign, they were not considered as a serious factor in the war and there was no organized air service which could

give an idea of the value of aeroplanes in war. The value of aeroplanes in war is not a matter of opinion or of conflict between the various types of aeroplanes, or the attack and defense of aeroplanes by way of the air. We have seen in the recent war the Turco-Italian campaign in the Balkans for aerial supremacy, and although the Italians had a one-sided, in that the Italians had three kinds of aeroplanes, dirigibles, aeroplanes and captive kite-balloons, whereas the Turks had none, the air service of the former was organized and worked systematically and achieved certain definite results on which we can begin to formulate opinions. On the whole, we gather that both aeroplanes and dirigibles were of great use to the Italians in the matter of reconnaissance. On rare occasions they assisted the artillery to find targets and regulate their fire, and they even tried the staff to correct existing maps by means of photographs, but with regard to dropping bombs the effects of the latter were decidedly more rather than material.

In certain limited cases as regards inanimate objects of attack, aeroplanes might be effective, as for instance for the destruction of railway lines, since "moving" number of bombs, while the machine kept above a length of permanent way, would not be very difficult. As regards the destruction of fixed points, the aeroplanes is practically useless, unless large numbers are used, and even then the results are not very certain, being comparatively close to the ground. Even so, the difficulties in obtaining accuracy of aim from the swiftly moving machine are very great. Besides this, the Italians found that even in face of the indifferent marksmanship of the Turkish aeroplanes, they were able at an altitude of 4,000 feet in order to remain out of range of fire. There is no cover in mid-air, and if the bomb-droppers should descend low enough to take any kind of aim, the attacking aeroplanes would have to run the gauntlet of a fusillade so heavy and sustained as to make serious losses. The chances of escape from destruction very slight. Ranging on aeroplanes has been shown to be extremely uncertain on account of their speed, and for other reasons, but the sustained fire of many rifles within say 1,600 feet and increasing distances of adjustment would eliminate the process of range-finding. On the whole, the damage likely to be done by aeroplanes dropping bombs is negligible, the moral effect on good troops most uncertain, and not worth the expenditure of gallant lives and machines which are of much more value for purposes of reconnaissance.

## Rail Inefficiency

**I**T has been said that there is no more efficient product of human industry than the steel rail, and this is probably true, but it is also true that there is hardly any element in industrial activity which is so inefficiently applied.

This fact will become apparent when it is considered that a rail is stressed almost to the limit of its endurance, under violent shock and heavy pressure, for a few minutes at a time, and then allowed to remain practically idle for several hours. With the exception of the rails used in and about terminals and yards, it appears that, for a very considerable percentage of the time the entire roadbed of a railway system is idle, while for the balance of the time it is violently over-worked, and the men who are employed to operate the work his men in such an irregular and erratic manner.

During the past decade the burden upon the rail has been greatly increased, both as regards engine work and freight, while attempts have been made to improve the rails in form, weight, and construction, the fact still remains that it is subjected to conditions far more severe and unusual than almost any other form of structural material.

Just where the remedy lies remains to be determined, but it seems that before attempting to produce a stronger, or more costly rail, the desirable method of procedure would be to attempt to use the present rail in a more efficient manner. The real usefulness of the rail lies in the carrying capacity, in its effectiveness as a means of transport, in its ability to carry the maximum loads and increase in frequency of trains as would give maximum capacity with nearest approach to uniformity in burden, would apparently lead to maximum efficiency, and to such reduction in stresses as would render obsolete the present rail.

It is possible that such a method of operation would, at first, fail to meet with the approval of traffic managers, as tending to increase the loss of operating; but when the limit of capacity is attained, it seems to be nearly the case, not only with the rail, but possibly with every other form of transport. The result of the plan, we may be pardoned to inquire whether the present use of the steel rail is not simply one among a number of indications that present methods of operation have almost reached their limit of maximum capacity and that a new method of operation is almost essential to the entire business of the country.

# Electricity

**Stripping Shrouded Wire.**—Now that enamelled wire is coming extensively into use for winding electric magnets and for similar work, it is of interest to be able to strip the ends of such wire in a ready manner so as to connect it to the other parts of the circuit, to leave the ends bare. Where the wire is very fine, it is a very difficult matter to strip the enamel without breaking the wire, so that the present German method is a timely one. The ends of the wire are dipped for a few times in boiling potassium cyanide or in concentrated sulphuric acid, or again in a concentrated and cold lye bath, then washed for an instant with hot water and dried by dipping in alcohol. This leaves a clean surface of metal for soldering.

**An Electric Ice-cream Press** has been devised by a London inventor. In the usual freezer tank, generally of large size for wholesale manufacture, hotels or the like, is mounted a tubular coil supplied from a carbonic-acid machine which takes the place of ice and salt. The small machine is mounted on a wall frame together with a small electric motor which drives it by belt from above, so that the outfit takes up very little floor space. Cleanliness is secured by the entire absence of crushed ice and salt, and there are no wet floors. It is claimed that the electric device also gives considerable economy in working. Another point is that where there are electric motors in use for other purposes, the ice-cream machine can be driven from them without entailing the extra expense of a motor.

**Packing for Lamp Bulbs.**—What is known as the "orange" packing for electric lamp bulbs is proving quite a success in France. It consists of an individual wrapping for each lamp which was at first devised for transportation of eggs, whence the name, and was afterward made in a suitable form for lamp bulbs. It consists of a cone-shaped shell made of corrugated paper with the corrugations running parallel to the length of the lamp. The envelope fits tight upon the lamp and is opened entirely down one side so that the wrapping can be opened out for inserting the lamp, still just as tight as when closed, hatching folds. At the top is a small narrowed part which surrounds and protects the pointed end of the bulb. In this way the lamps can be simply packed in boxes like any kind of loose material without needing any further precautions.

**An Electric Gas-analyzer** has recently been produced which enables us to give a series of rapid analyses of furnace gas so that the composition may be ascertained. Usually the amount of carbonic acid (or oxygen) is determined in this way. An electric motor operates all the parts and the rapidly succeeding analyses are recorded on a paper drum in succession. By raising a small water gaugeometer bell to a given height by the motor, a standard amount of the furnace gas is drawn in, then it goes into a potash absorption chamber where all the carbonic acid gas is absorbed. The remainder passes from here into a second gaugeometer which reads the end of a lever and the height according to the amount of gas sent into it. Should no gas be absorbed, the second gaugeometer receives the full 100 per cent of the standard amount, and the pen attached to it by a light arm now rises to the top or to the zero line and makes a dot by an electromagnet device, showing no carbonic acid. Were 30 per cent absorbed, it would rise less and indicate this latter amount. Then the gas is evacuated and a fresh analysis made, so on quite automatically, once in about every five minutes.

**An Ocean Telephone.**—Og May 1st what is probably the first ocean telephone call station was opened for public use. This is in the Pointe-aux-Loups lighthouse on a rocky islet about 1½ miles to the northwest of Guernsey, Channel Islands. The lighthouse, which has no keeper, is fitted with a powerful fog signal, worked from shore by means of a submarine cable. In a fog ships creep up guided by the fog horn and fog siren and anchor near the lighthouse until the fog lifts sufficiently to enable them to take the narrow channel to the harbors of Guernsey. In such case any pilot or ship's officer by climbing the lighthouse can ring up Guernsey and get the necessary support. The telephone is reached by climbing a 45-metre ladder to the platform outside the lighthouse doors. Before he can leave the ladder the pilot pushes open a trap door which covers the manhole in the platform. The arrangement is such that the pilot cannot open the lighthouse door to reach the telephone until he has shut down the trap door over the manhole. The act of opening the outer lighthouse door connects the telephone fitted outside the inner door of the lighthouse, which is kept locked. Only one wire in the cable is available for the telephone, and even this wire is required for other purposes, and closing the door after closing the telephone connects up several telegraph lines. The lighthouse door cannot be left open by the lighthouse keeper; the pilot must close it again by the same door. The pilot must be able to reach the door in order to get the trap door in order to reach the telephone.

# Science

**Photographing the Aurora.**—Prof. Stormer and Dr. Birkeland spent the months of February and March at Roskilde, in northern Norway, making photographs of the aurora, continuing the remarkable work of two years ago. As in the previous case, photographs have been taken simultaneously from two stations about 2½ miles apart, connected by telephone, in order to furnish means of computing the distance and altitude of the aurora.

**Signal Lighting.**—Photography long ago proved that there are no taken for signal lighting is really useless, i. e., without sharp angles. Otto Melsener, in *Die Welt*, reports on the results of the analysis of the angles of lightning. He believes that the sudden glare of the flash causes an involuntary movement of the head or eye, the original image of the flash persists for a moment on the retina, along with the image produced on the eye in its position. Thus we get the impression of a broken line.

**Canadian Weather Forecasting** is the subject of a useful brochure just published by the assistant director of the Dominion meteorological service, Mr. H. C. Webster. The writer is perfectly frank as to the unsatisfactory scientific state of weather prediction, and attempts to give only a glimpse of empirical knowledge, but lets us know what work is carried on in Canada. It would be an excellent plan if the forecasters in all other countries would put the results of their practical experience on paper in the same way.

**A Superstition Concerning Mountain Sickness** is reported by Mr. W. Bryan Douglas to prevail in Bolivia, was a superstition that there is some cause for the affliction and the presence of large mineral deposits in the mountains. This belief is reflected in a Bolivian name for the disease—"veta"—meaning literally a lode or vein. The natives thus attempt to explain the fact that the disease is more or less local in occurrence, and does not appear to depend solely upon altitude. The pass of Liviachuo, on the trail from Challapala to Sucre is known to contain large deposits of antimony, and is considered a bad place for "soroche" (mountain sickness), some travelers dying when crossing it.

**A New Variety of Bean** adapted for dry climates was discovered by former residents of Peru. W. C. Schell, of the University of Arizona, as reported by him in a recent magazine article. During a 1,300-mile wagon journey over the deserts and mountains of Arizona in the summer of 1908 he visited the Papago Indians, and obtained from them several hundred leucous-yellow beans of an unknown variety. These were sown on experimental plots at the Arizona Experiment Station for four years before the discovery was announced. It appears that the new bean, which has been named "leary," is more prolific under dry conditions than any other known variety, yielding as high as 720 pounds to the acre with no water other than the scanty rainfall of Arizona. Under the same conditions ordinary beans yield only from 60 to 164 pounds to the acre.

**Uses for Calcium Cyanamid.**—It is only a few years since it was discovered that nitrogen passed over hot calcium carbide formed a compound valuable as a fertilizer. It is converted into ammonia in the soil and so can be used as a substitute for nitrates. More recent practice passes steam over the cyanamid and converts it into ammonia in the factory. The catalytic action of osmium and thorium oxides on ammonia and air makes it possible to convert it into nitric acid, then nitric acid into a new material.

**Purification of cyanamid with sodium silicate** converts it into cyanide, valuable in gold mining. By treating cyanide with water just below the boiling point dihydrocyanide is made, a compound useful in the dye industry and in the making of explosives. In Germany they are selling under the name of "Perodur," "Isodur," "Hosodur," etc., materials for case-hardening steels. These powders are merely compounds of cyanamid with some alkaline salt and carbonaceous material.

**Taking Criminals' Finger Prints on the Spot.**—Dr. Heintz recommends a very good method for taking the finger prints of criminals, this not relating to finger-prints as such, but to the anthropometric branch, but where the record is to be taken on the spot where a crime occurred such as on a wall or any object which cannot be moved and where the print is impossible to photograph on account of lighting or other reason. He makes use of a very fine color powder so as to fix it over the points which are of a more or less greasy nature, and in this way the powder adheres to the finger print and takes all its gradations. Then a specially prepared paper is pressed upon the print and the powder adheres to it so as to give a good copy of the original skin. The paper is prepared with a mixture of beeswax and paraffine adding a few drops of glycerine, coating the paper with a thin layer of the same. The paper is of a very flexible kind so that it fits upon the surface of irregular objects. It is said that a gelatine or adhesive paper is a good means for taking of prints of this kind, and can be employed with success.

# Automobile

**A Pneumatic Anti-slip for Automobiles.**—Patent No. 1,058,044 to Benjamin Douglas, Jr., of Orange, New Jersey, presents an automobile with an explosion engine, an ordinary muffler and a secondary muffler, which last is partly filled with sand and into which the exploded gases are discharged and subsequently elements and both mufflers are connected with the explosion engine and connections are provided from the secondary muffler to convey the silenced gases and some of the sand in front of and on either side of one or both of the driving wheels of the motor vehicle. The sand is so arranged that it can be used to spread sand to prevent slipping of the wheels.

**The "Dog-Sled" Body Is the Latest.**—We have had submarine bodies and aeroplane bodies, one designer has gone so far as to bring out a terra-marine body, and now comes the "dog-sled" body which is said to represent the very utmost of perfection for touring service. The "dog-sled" body is simply an ordinary touring body, or rather a torpedo body, in which the sides are extended to include the running boards, thus providing ample space for the storing of tool boxes, parts, etc. The spare tires are accommodated in a bulbous back and the side door, giving entrance to the compartment over the step, is wide enough to pass a rather large truck. The horns and the lamps are quite invisible and when folded the top disappears into a compartment at the back of the body. When in touring trim, the car is said to be waterproof.

**Automobile Omnibuses in France.**—The great extension of automobile traffic in France has led to the use of services in the country districts will be seen when it is observed that there are already 203 different omnibus lines running at present, a total distance of 5,540 miles. The types of autobus or alpin car are supplied by 25 different works, many of which are in the neighborhood of Paris. The different lines which we mention are organized by 179 transportation companies. When it is noted that these of four years ago there were scarcely thirty of these autobus lines in operation, the progress made in a very recent period is striking. Even now the motor is at the outset, and just lately the simplest problems of operating services of this kind were but little known, leading thus to a limitation on the part of the communes and the State to furnish subsidies. Lack of co-operation among the companies was another drawback, but the State has intervened, and the forthcoming operating data are encouraging the authorities in the matter of subsidies, while the methods of the lines are becoming better established. A general transport syndicate is lately organized, a starting point for the future, which will be a great help to the State. From this time on, a brilliant future is predicted for automobile passenger service. A few examples will show the kind of service in use, for instance the Nios Company operates 10 Buick autos in the Maritime Alps region from Nice to Brignone, a total of 170 miles. Another enterprise operates a line from Avignon to Arles, 65 miles. A line from Grasse to La Londe, operated by the Touring Car enterprise, covers 50 miles with Peugeot and other cars. The Auto Transport firm has 8 autobus running between Aix and Marseille, 100 miles. Another enterprise has four lines radiating from Montpellier and using 9 Du Pont cars, with a distance of 102 miles.

**Improvement in Motorcycle Magneto.**—If the solution of ignition problems has done much to advance the automobile built as severely can have done less to advance the motorcycle. While the latter is a simpler machine to modify almost any kind of ignition apparatus on an automobile, regardless of its complexity or bulk, the equipment of the motorcycle presents problems which are entirely foreign to any that can crop up in automobile work. In the first place, the magneto is so small that the ignition apparatus on a motor cycle occupy the smallest possible amount of space, for space is at a premium and the rider can ill afford to have his machine fettered down with wiring and cluttered up with batteries and vented and cooled air. In the second place, it is even more important that the apparatus which produces the life-giving sparks be waterproof. In these respects, it is interesting to note the really tiny size of the modern motorcycle magneto and the degree of waterproofing it has attained. In the following some of the cases the magneto is a miniature instrument practically built integral with the motor from which it is driven either by inclined gearing or by a chain of the "aleut" variety. It forms a neat contrast to the bulky and weighty batteries and coils which only a year ago were standard equipment on all but a very few machines and marks very plainly one very big step forward that motorcycle and magneto manufacturers have made within the past twelve months. Also, these newer types of instruments are waterproof. In the following some of the word—a statement which would not have been applied with any degree of truth to their predecessors. Without exaggeration, they will operate efficiently with a continuous stream of water playing on their "vitals" without the slightest apparent injury to their spark-producing parts. In fact, "Beating up" the instrument with the instrument has not been an easy task, though it nevertheless has been thoroughly done.

## Lightning-Prints

## A Curious Chapter in the Pathology of Lightning Stroke

By Charles Fitzhugh Talman

Fig 1—This example and that of Fig 3 are photographs obtained by interposing a sensitized plate between poles of an electrical machine

Fig 2.—This combined plate-print and that of Fig. 1 strongly resemble the typical lightning-print shown in Fig. 2.

IN the light of your mind there is probably the vague  
impression of having heard that sometimes after a  
person has been struck by lightning the photographic  
image of a nearby tree or other object is found im-  
pressed upon the body. This is one of the ten thou-  
sand weird and neglected subjects that will be fully  
discussed in this yet unwritten and unplanned Para-  
lymnia. I expect you will be as anxiously awaited  
as the other members of the group. I think I have  
collected a few things left out of the conventional  
reference books. The aggregate of the existing liter-  
ature of the subject scattered through several languages  
is fairly extensive and the marks in question have oc-  
casionally been drawn and even photographed from na-  
ture. They are called lightning prints or keraunog-  
raphs.

For our present purpose it will be convenient to distinguish two classes of lightning prints viz (1) arborescent forms popularly supposed to be photographs of trees or other vegetation and (-) a variety of other

There is no doubt of the frequent occurrence on the bodies of persons who have been struck by lightning of ramifying marks strongly suggesting the appearance of tree branches, and the accompanying Fig. 4 is drawn from a photograph of such marks on the arm of a boy struck by lightning near Inns Fugland June 30th 1944. The photograph was taken four and a half hours after the accident. Some beautiful colored plates of similar marks (unfortunately too delicate for reproduction here) are given in 84 *Illustr. Atlas der Fichtkropfologie*. (1936).

harmfully by many scientists, even as today by the laity such marks were believed or at least suspected to be the result of an actual photographic process on the part of the lightning. The following quotation from an interesting print anecdote published in *Chesbrough's Journal* for November 1861 emphasizes the old belief:

"During the storm at Lappon, France, six workmen and a child received severe shocks and a woman of fifty-four years of age had the image of a tree struck on her forehead, and a man near by was struck upon her person. There appears no doubt that in all these cases of lightning prints the image produced upon the body indicates the object from which the electric discharge was emitted. In other terms, that the object which is struck is produced formed part of the electric circuit. The same idea is more wrapped up in technical terms, and is the subject of more scientific discussion of the subject of lightning in recent days. Camille Flammarion in the 1st number of his two anecdotal works on lightning, devoted a chapter to lightning prints in which he suggests the existence of ceramite rays, or rays of a kind resembling that of photographic light on the skin of human beings, lower animals and

plants more or less distinct pictures of objects far and near

Détails of the recorded case of lightning prints will be found in A. Poy's *Relation historique et théorique des images photo-électriques de la foudre*, Paris, 1864 (on which the above-mentioned article in *Chambers's Journal* is based) in three memoirs by J. C. M. F. de la Rive, *Ann. Chem. Phys.* 36, 1865, 1866, and 1867 (in this connection) in O. Tomlinson's article On lightning Figures published in *Nature* May 28, 1878 in Pannerman's book just referred to and in many other works. In by far the greater number of these arborescent forms are said to have been produced by lightning strikes on glass plates. They are generally disappeared in a day or two. In the original narrative it is nearly always assumed that the marks represent some particular tree or part of a tree, in the neighborhood and it is frequently stated that this image was reproduced with absolute fidelity. It is hardly necessary to say that it is doubtful whether the eye is really in the ability of lightning to produce such

there are several cases on record in which lightning-prints have been identified as photographs of leaves.

In opposition to the popular belief there has always been a certain amount of skepticism on the part of the less scientific man who has interested themselves in this subject as to the photographic character of the phenomena. In 1891, the German physician, Dr. H. H. E. attributed to Gehler's "Psychisches Wörterbuch" (new ed. 1893) cases to identify those marks with Lichtenberg figures. A more plausible explanation, which must have occurred to many people before it was definitely suggested by W. Stricker in 1901\* was that these marks were produced by the discharge of electricity from the vessels, made visible by injection or extravasation under the effects of the electrical spark. However this hypothesis was disproved by Rindfleisch\* who dissected the body of a man killed by lightning, and who found the above-mentioned prints did not coincide in the least with the position of the vessels. Rindfleisch's experiments have shown that Rindfleisch we are indebted for what is, in all probability the correct explanation, and it is a very simple

one. According to this writer the ramified marks represent merely the junction due to the passage through the air of a branching electric discharge. The heat generated by such a discharge against resistance accounts for the alteration of the flames in this as in other cases of electrical injuries and the branching of the spark is due to the different resistances so countered as is true of ramified sparks in general (e.g. those seen in ordinary photographs of lightning and lightning rods). Further particulars on this subject will be found in the article on lightning injuries (by S. Jellinek) in the recent fourth edition of Rosenburg's *Reiz- und Elektrifizierungslehre* (Hirschwald) vol. 2 p. 581 ff.

6.—Three pieces of part of a tree struck by lightning, showing lightning prints on their surface. (After Lawson.)

Fig 2.—Aberescent lightning-prints. Drawn from a photograph of such marks on the arm of a boy struck by lightning near Dunn, England, in 1883. Photographed four and a half hours after accident. (From "The Lancet.")

Fig 4.—An alleged lightning photograph of a neighboring poplar tree (After Flammarion.)

Fig. 5.—Three pieces of the bark of a tree struck by lightning, showing lightning prints on their inner surface. (After Tomlinson.)

photographs there is an excellent opportunity for self-deception as to the accuracy of the supposed delineations. This fact is well illustrated in one of the cases recorded by Flammarion. A man named Billeon was struck by lightning at Pertuis, France, June 17th, 1866, and was killed. He was buried in the cemetery of Pertuis, and had been found upon his back. M. Flammarion corresponded with the surgeon who attended the case, and Dr. Tournairet. The latter confirmed the newspaper report stating that the Billeon undoubtedly represented a poplar tree, standing a hundred meters from the place of the accident. Unfortunately for a good story, the photograph of the Billeon, which was made from a print (Fig. 4) The outline is, to be sure, somewhat suggestive of a poplar tree, but only a mind strongly predisposed with the belief that such marks are always photographs of nearby objects could have so readily identified it with the tree in question. In passing, it may be remarked that the very slight addition in the lower part of the trunk to the trunk of the poplar, is a "tail." This is described in view of the fact that

## Manufacturing Problems

A New Field for the Industrial Scientist

By F D Bell

Fixing the chemical purity of water for use in bottled goods.

THE nature and uses of a factory product determine whether the manufactured article should be the result of combination of several raw materials to form chemical compounds possessing properties distinct from those of the raw materials as, for instance, in glass manufacture, or, whether the manufactured article is the result of partial chemical combination—as in rubber goods—or, finally, whether the particular manufactured product is the result of simple mixture, as in the case of many pharmaceutical and household articles.

In the case of chemical combination, various conditions materially affect the resultant product. The physical conditions, such as temperature and time of interaction, are frequently most important, but strength and purity are very essential. The manufacture of glass, while in all cases the result of combination of similar basic constituents, such as silica and the alkalies, may, by the addition of special ingredients, yield products having the most infinite variety of properties. In this manner window glass, plate glass, lamp globes, bottle glass, thermometer tubing, chemical glassware designed to resist the action of chemical solutions, pyrex glass designed to resist the action of hot water and sudden changes of temperature, various colored glasses, and a host of others, are the result of proper combination of ingredients which give the desired properties to the finished product.

The manufacturer of hydrogen peroxide has spared no effort in searching for a suitable preservative which will enhance the stability of his solutions. Of the greatest importance is the quality of the glass in which the product is bottled, since glass which is readily acted upon by aqueous solutions greatly accelerates the decomposition of hydrogen peroxide.

Alcoholic and aqueous liquids and bottled table waters frequently contain sediments which are the direct result of the action of these fluids on the glass container. In some instances, the alkali of the dissolved glass neutralizes the acidity of liquids to the extent of causing secondary reactions to take place, and in this manner induces certain chemical changes to follow. These changes result in seriously altered flavors and precipitates, which render the product unsalable.

Bottled, non-alcoholic, drinks are subject to many other troubles than those due to the nature of the glass. In some known instances, which it is probably safe to assume are typical of conditions throughout the trade, these prepared drinks are made without any regard to the chemical principles involved, the chemical purity of the raw materials, or the methods employed in setting the ingredients together. Water containing large amounts of lime and magnesia may, with certain fruit acids, cause the direct formation of an insoluble compound which appears as a sediment after the goods are marketed.

Certain grades of caramel coloring, commonly known as burnt sugar coloring, may under certain conditions contain by-products formed in its manufacture, which, when brought into contact with certain flavoring extracts, will cause very dense sediments to form within a brief time after being put up. In such cases the bottled beverage may be only slightly opalescent when freshly put up, but after a number of days—sometimes weeks—may develop the dense precipitates. The manufacturer must always call to the appearance of the product, whether or not it is salable, and his first step should be to remove from some complete set of samples the chemical bodies of these materials would cause. The chemical bodies of these materials would cause the dense precipitates. The manufacturer must always call to the appearance of the product, whether or not it is salable, and his first step should be to remove from some complete set of samples the chemical bodies of these materials would cause the dense precipitates. The manufacturer must always call to the appearance of the product, whether or not it is salable, and his first step should be to remove from some complete set of samples the chemical bodies of these materials would cause the dense precipitates.

beverages which are sweetened with cane sugar, and not otherwise preserved, require the most careful attention on the part of the manufacturer owing to the readiness with which weak solutions of cane sugar undergo fermentation. A product which is crystal clear when bottled will often in the course of several days, depending upon temperature, develop a cloudiness and

Centrifuge used for whirling out sediment found in bottled goods.

deposit a sediment of yeast cells. It is only with scrupulous care and cleanliness in the washing of bottles and in the compounding that difficulties of this nature can be overcome. A syrup which shows but slight evidence of undergoing fermentation will in variously impair the appearance of the finished beverage.

Fixing microbe-free organisms which cause spoilage in bottled goods.

Even ice manufactured from distilled water frequently contains sediments which appear in discolored patches throughout the cake. When such ice is melted in a clean vessel, a deposit is seen on the bottom. In most cases sediments of this character are produced by impurities of the tanks in which the ice is formed. Many other articles of commerce are subject to

Determining the specific gravity of syrup for bottling.

changes which result in the formation of sediments. In one instance a month was contained, among other ingredients, boric acid and water extract of a bark rich in lime. After being on the market for some time, a heavy sediment deposited in the bottles, which upon analysis was found to consist of calcium borate. In this case a natural constituent of one of the ingredients was incompatible with one of the other substances contained in the preparation. It was only necessary to eliminate the lime from the bark extract in order to correct the difficulty.

It is therefore apparent that a great many commercial products are seriously affected in appearance by the formation of sediments from varying causes. Sometimes a sufficient quantity of the sediment may be obtained for chemical identification, but in many instances it is necessary to resort to micro-chemical methods. The microscope is a most valuable adjunct to the study of problems of this nature.

While certain rubber manufacturers compound their rubber goods under strict scientific supervision, there are many instances where such goods are still manufactured without regard to sound chemical principles. In the first instance, raw materials are purchased according to the quality desired and at prices commensurate with quality secured, whereas, in the second instance, the purchasing agent takes a haphazard fling at the representations of the salesman and is particularly apt to choose the article which is lowest in price and seems to possess the necessary qualifications when in a batch of rubber happens to be ruined, the factory foreman is held responsible.

The importance of compounding rubber with a view to securing a satisfactory article for a definite purpose is too rarely considered. Naturally a composition intended for tires cannot be expected to resist stress and in the manifold applications of rubber goods it is necessary that the composition should be so controlled as to yield an article of a quality satisfactory for a given purpose.

Many a rubber manufacturer has had goods returned as being worthless because the user found that they did not "stand up" under the conditions to which they were subjected. He naturally assumes that the manufacturer has supplied him with an inferior article, whereas the real reason is that some chemical or physical change has resulted, owing to the manner in which the rubber was used. A concrete example that aptly illustrates this point is that of a rubber manufacturer who employed whitening in some hose that was to be used for conveying a slightly acid liquid. The acid attacked the whitening in a short time and left the hose pitted and unfit for further use.

Compounds containing lead and zinc are frequently used in rubber goods, which, in some cases or other, come in contact with food products, and in the event of such foods being slightly acid, contamination with lead and zinc would most likely take place. Germany is considerably in advance of our own country in this respect, since a law which went into effect on October 1st, 1898, prohibits the use of rubber containing lead and zinc in nipples for babies' feeding bottles, teething rings and similar articles. Rubber containing lead is prohibited in rubber tubing used for conveying beer wine and vinegar. Toys, with the exception of large balls, must not contain rubber compounded with lead.

Perilous problems continually come up for solution in the manufacturing industry. As an example we might consider the case of hydrogen peroxide. Everyone is familiar with the fact that the solution of hydrogen peroxide deteriorates on standing. In order to enhance the keeping qualities, it is customary for the manufacturer to add a certain proportion of acetic acid. While it is known that hydrogen peroxide solutions containing acetic acid develop unpleasant

odors on long standing, yet there are certain conditions which, if not properly considered, will result in an unusually rapid development of such odors.

One manufacturer had his entire business threatened on account of a peculiar odor resembling iodoform, which developed in his hydrogen peroxide in less than a week after it was first produced. He had discarded the conditions responsible for the peculiar phenomenon and no further difficulty was encountered after proper changes in the process were instituted.

Even to-day certain manufacturers fail to realize the economies which result from a proper utilization of their waste materials. In the manufacture of hydrogen peroxide barium sulphate (technically known as *blanc fixe*) is obtained as a by-product. One manufacturer allowed this product to run down the sewer, whereas he could have obtained a ready sale for a ton if he had taken the trouble to press out the water and put it in barrels.

The manufacture of hydrogen peroxide is of a type which requires chemical supervision in order to produce a satisfactory product at a reasonable cost. It is necessary to know the strength and the purity of the raw materials used and the yield of hydrogen peroxide obtained as well as the strength, purity and permanent use of the finished product.

Manufacturers of disinfectants, such as coal tar and cresol, and acid dips, have been long improved with the need of a scientific supervision of their products. While many of the larger factories engaged in this work are scientifically controlled, there are still many factories where "rule of thumb" methods prevail. The finished product in these cases is liable to be of a certain antiseptic strength, and to accomplish this, the composition of the coal tar oils must be ascertained in order to obtain a uniform product. The manufacturer itself must be so controlled as to yield a homogeneous mixture, which will give a proper emulsion on dilution with water. Recently many of these manufacturers have been interested in increasing the germicidal power of their products, and this simply emphasizes the effect which bacteriological science has had in establishing the fact that the germicidal power of these products was greatly increased by the addition of the germicide. This is true not only of the coal tar disinfectants, but of many other types as well, for instance, of such products as tooth pastes, mouth washes and similar articles used in the household.

The subject of chemical control is not to conduct chemical analysis simply in order that only the very purest materials may be used in technical manufacture. There is a limit to the purity required of certain materials used in the industries and it is the chemist's duty to select these materials in accordance with a required standard and to sell them at the lowest possible price. Thus, for instance, the case of abrasives used for polishing glass lenses. A certain abrasive is required which possesses the requisite degree of fineness, so that it will not scratch, and furthermore it must have a certain degree of hardness in order to secure the proper cutting qualities. (Of course, the idea is to have an undiluted material which shows the desired mechanical efficiency. One of the abrasives used for this purpose is rouge or red oxide of iron. This occurs in varying degrees of purity, but the prices of rouge depend upon the mechanical treatment to which the product must subject the material in order to secure the desired qualities. It then becomes the function of the chemist to advise the user in regard to the grade of material which would be satisfactory for his purpose and to sell it at the lowest price at which the proper price at which it is offered to him is reasonable.

Many instances exist where the manufacturer never consults the chemist until he experiences difficulties. This is by no means unusual, and the manufacturer who consults the physician until illness forces him to seek medical advice. However, we must not lose sight of the fact that human beings are somewhat capable of knowing when their physical condition is such as to require medical attention, while it is impossible for the untrained manufacturer to know when his difficulties until perhaps the consumer rejects the goods which have been delivered. The consumer's first impression is that an inferior or adulterated article has been supplied and it is sometimes exceedingly difficult for the manufacturer to restore the confidence of his customer. The case of a lubricating grease manufacturer who regularly had complaints from his customers owing to the peculiar spots and discolorations which developed in the grease, is an example of how some manufacturers neglect to remedy imperfections in their processes until the product has become so seriously defective that it is practically every industry where a chemist's services are vitally necessary, and where there is a fallacy to employ a chemist, one finds a lack of definite knowledge of the products manufactured, as well as a lack of criminal law knowledge of the consumer's complaints, posing as manufacturing chemists, reap a harvest from such firms through the sale of "special-

ties" claimed to possess certain properties. There are many instances where factory managers purchase products, which, while apparently giving the desired satisfaction, are nothing more than ordinary well known compounds sold under fanciful names. In one instance, a compound was offered to a grease manufacturer which was said to be worthy the talisman. The manufacturer demonstrated that the action of the chemical was simply that of neutralizing the fatty acids of the talism.

This same effect was accomplished in the process of the manufacture of the new "grease" was entirely unnecessary. There is absolutely no objection to the company which markets an article having distinct and desirable properties in any given line of manufacture and secrecy is rarely necessary when the product has real merit. In the purchase of "specialties" the factory manager would do well to seek the services of a chemist in establishing the true value of the product in question.

As in the case of "household" articles such as polishes for metal and furniture, washing powders, cosmetics, etc., there is likewise a tendency to develop "novelties" for the benefit of investors. Many an inventor has been rationally interested in some new and remarkable "development of chemical science." There are many instances where investment in chemical products has been made, and the inventor's process is based upon thorough scientific principles and a knowledge of commercial conditions, but the wise investor will rely upon the chemist's help and advice regarding new developments of chemistry, and not plunge into the unknown with his capital.

### Maiden Voyage of the "Imperator"

Some Features of the First 900-foot Ship

By J. Bernard Walker

THE "Imperator," the world's first 900-foot ship, was launched by the German Emperor on May 28th, 1912, from the yard of the Vulcan Works, Hamburg. By the time she floated on an even keel, the great ship displaced some 27,000 tons of water. This was the largest displacement yet recorded, and its significance will be realized when it is stated that the mere shell of the ship, as thus launched, weighed more, by 4,000 tons, than did the famous "Deutschland" of the same company, built in 1900, when she was completely covered with full coal bunkers, provisions, and carried a full passenger list. When the "Imperator" steamed to the westward on her maiden voyage she weighed, or displaced, much more than double her launching weight, for her displacement at maximum possible draught is not far from 50,000 tons.

At the front end of the ship is the massive American liner, from the back of the huge bronze eagle that projects from the stem, to the stern, is 910 feet, and if we neglect the eagle it is 900 feet. The beam is over 88 feet, and the plated depth is 75 feet. At the front end of the "Imperator" is the lower bottom of the ship, and the deck that runs in the topmost tier of rooms, such as the ballroom, winter garden, etc., the "Imperator" has no less than twelve decks—that is to say, she is a 12-story building afloat. Nor is the comparison misleading as a measure of the towering height of the ship, for the first thing that strikes the visitor on going aboard is the unusual height between decks, which in the case of several decks is from 11 to 12 feet. Now 12 to 12½ feet is the average height between centers of floors in a modern New York skyscraper. The length of the ship is not so great as these towering ocean liners, which tends to dwarf their height, they would realize that an "Imperator" is a veritable skyscraper of the sea.

If the ship were to be placed in Broadway it would be necessary to cut it in two beyond the building line on each side of the thoroughfare for a length of four city blocks, and the top of the topmost tier of store-rooms and assembly halls would extend far above the roof line of the six and seven-story buildings erected in the pre-war period.

At the first sight of such a ship as the "Imperator" one fails to grasp its magnitude. This is due to the fact that every dimension of the huge structure is increased in its proper proportion. Thus, the 900 feet of length is offset by the great height of the superimposed decks, overtopped by the huge masts, each 30 feet in its largest diameter. It is only when one of the so-called monster ships of an earlier date is ranged alongside that the overpowering size of the ship of 1912 is realized.

Another class of measurement that tells the story of size is to consider the dimensions of superstructure of the ship. Thus, a single watertight bulkhead, amidships, weighs 60 tons. The shaft jacks or stays weigh 30 tons apiece. Each of the four propeller shafts is 1½ feet in diameter, and each of the four bronze propellers is 12 feet in diameter. The two main shafts are 37 feet in diameter, and 32 feet long, and the rotors within them are fitted with 50,000 blades

(the largest 5 feet long, and those weigh 140 tons. The smaller weigh 90 tons, and the smallest and its leaf-shafts weigh 110 tons).

The motive power of the "Imperator" consists of four main turbines driven by four shafts, each for the turbines being supplied by steam-turbine boilers. These steam-turbine boilers are an innovation in the case of the shipbuilders for the merchant marine have hitherto clung tenaciously to the Scotch boiler—a fine type, it is true, and thoroughly reliable. They have failed, largely through conservatism, to follow the lead of the naval engineers, who many years ago discarded the Scotch for the later type. The Hamburg-American Company are to be commended for breaking away from a too long entrenched practice by adopting the more modern and effective type.

The safety of the "Imperator" is assured by a complete inner armor from the bow to the stern and of the engine rooms. Forward of the boiler spaces this skin is worked from 4½ to 5 feet in from the outer shell. Throughout the length of the boiler spaces it consists of the inner wall of the longitudinal bulkheads. The bulkheads extend a height of not less than 20 feet above the waterline, throughout the central two thirds of the ship, toward the ends they are carried higher, the collision bulkhead extending to the upper deck. In their construction close attention was paid to the question of distortion, and the hull was strengthened by heavy I-beams and other shapes to withstand, without distortion or leakage, the pressures which would arise from maximum submergence of the ship due to under-water damage. Furthermore, to insure that the bulkheads were thoroughly watertight, each compartment was fitted with a valve to maintain possible leakage, and all leaks that developed were closed by coaling.

It is of interest to note that when the bunkers of the "Imperator" are filled she will carry some 9,000 tons of coal.

The maximum speed of the ship, on trial, was 23 knots. She carries a reserve of boilers, and it is probable that with all of these going under full pressure the "Imperator" could do 23½ knots.

The Maiden Voyage. The "Imperator" left Cuxhaven drawing thirty-five feet and displacing about 50,000 tons. The test of the seagoing qualities of the ship commenced at once with a head sea and a wind of a strength of eight out of a possible maximum of twelve. The writer, who was on board, was at once impressed with the fact that the ship was the newest of the world's latest and largest liner. The wing propellers, which in quadruple-propeller turbine lines have been hitherto a source of troublesome vibration, are in this ship placed well away from the hull, with the result that the rotation is comparatively quiet, and well away from the belt of water which is drawn along by the skin friction of the hull, and is now known to be a prolific cause of propeller vibration.

No effort was made to push the ship to its full speed. The speed varied from 20½ to slightly over 22 knots, the lower average speed being due to the period of delays due to fog and heavy head seas. Perhaps the most notable feature was the practically complete absence of rolling, or at least of such rolling as was perceptible to the senses. On two days there was a heavy head sea with wind on the second day blowing for several hours with about the strength of a whole gale.

The ship, under the pressure of the strong wind on her lofty superstructure, assumed a slight angle of heel, moving parallel with the waves with a steadiness that was remarkable, even in so huge a vessel. The absence of rolling of the ship is due to the marked advantage of the latest vessels of the "Imperator" type. Rolling can become severe only when the period of roll of the ship coincides with the period of undulation of the waves.

In the case of the "Imperator" the period of rolling was about two seconds, whereas the period of the waves on the days in question was about thirteen to fifteen seconds. It is evident that the larger the ship, the greater will be the differences of periods and the less the tendency to roll. Rolling on a ship of this size is negligible. The deck is in a certain position on the quarter, in which the ship is able to roll it runs with the sea may bring the period of roll and the period of the passage of the waves into coincidence.

The great depth of the ship—her stiffness as a glider—was soon to good effect when she was striking into a heavy head sea. The movement of the sea was in the upper part of the sea was only between a quarter and three eighths of an inch.

### The Articles on Prior Manufacture

IT has been found impossible to publish in this issue of SCIENTIFIC AMERICAN the article on the patent of the patent, to prior manufacture of small machines, which was provided at the end of the 19th century. The article is too long to be published in this issue, but it is of great interest, and it is hoped that it will be published in a future issue.

### Father Knickerbocker's Daily Fare

**WHAT** does the average New Yorker eat per day? This question is answered graphically in the illustration on our front page, which is based on estimates made by the New York State Food Investigating Commission last year. The annual bill for food is given at \$100,000,000. Assuming that this bill is paid by five million inhabitants, the daily cost of living in New York for the average individual is about 35 cents. The annual consumption of beef and other meat products is 890,000,000 pounds per year, costing about \$170,000,000, which amounts to about half a pound of meat per individual per day. If the meat were all beef, it would take about 8,000 horses to supply the daily demand. It would be impossible for us to show this number in our illustration. Accordingly, we have represented the figure by a single beef three thousand times as heavy as the ordinary beef. More money is spent for meat than for any other item in the food list. In this estimate of meat, poultry and fish are excluded. One hundred million pounds of poultry are consumed per year. Or, if the poultry were all chicken, it would amount to between 50,000 and 60,000 chickens per day, while 100,000,000 pounds of fish are consumed per year, amounting per day to about 2,000 five-pound fish. Next in importance is the canned goods, for which \$150,000,000 is paid yearly. The average New Yorker drinks a little less than a pint of milk per day, the daily consumption being about four quarts a day and over. It would take a milk bottle nearly one hundred feet high to hold this quantity of milk. New York eats also hundred million loaves of bread per year and as it is possible to make three hundred loaves of bread out of a single barrel of flour, the daily consumption of flour used in making the bread is a little over eight thousand barrels.

The following is the table prepared by the New York State Food Investigating Commission. Those who love to juggle with figures will find the table full of interesting possibilities.

### Quantity and Value of Food Consumed Annually in New York City

1. Beef and other meat products—890,000,000 pounds at 20 cents	\$170,000,000
2. Milk—800,000,000 quarts at 8 cents	64,000,000
3. Butter—100,000,000 pounds at 30 cents	30,000,000
4. Eggs—100,000,000 dozens at 30 cents	30,000,000
5. Bread—900,000,000 loaves at 6 cents	54,000,000
6. Canned goods—150,000,000 pounds at 7 cents	10,500,000
7. Poultry	
8. Potatoes—750,000,000 pounds at 8 cents	15,000,000
9. Fruit—150,000,000 pounds at 10 cents	15,000,000
10. Coffee—45,000,000 pounds at 25 cents	11,250,000
11. Other vegetables and fruit	8,000,000
12. Cheese—35,000,000 pounds at 18 cents	6,300,000
13. Tea—5,000,000 pounds at 40 cents	2,000,000
14. Cereals	8,000,000
15. Canned goods	150,000,000

\$254,850,000

### The Death of Ernst Ruhmer

**ERNEST RUHMER**, whose name is well known to readers of the *SCIENTIFIC AMERICAN* as one of the most fertile and ingenious of German inventors, died on April 25th last at the early age of thirty-five. He was a son of an engineer and was educated principally in the technical high school of Charlottenburg, and the universities of Berlin and Göttingen. After a brief association with a prominent German instrument maker, he established an electro-physical laboratory. Among his inventions are an apparatus for determining the number of interruptions of fluid interrupters, an instrument for photographically recording and acoustically reproducing sound waves with the aid of a selenium cell, a multiple microphone, a selenium photometer, a device for determining and registering the intensity of daylight, an arc-light interrupter, a television apparatus, and a system of light telephony in which selenium cells and searchlights were experimentally used with great success.

**London Chamber of Motor Experts.**—To take up what has long been regarded as a subject of careful consideration, there has been formed in London an organization styled the London Chamber of Motor Experts. The expressed purpose of the Chamber is to take under advancement such patents as inventors deem valuable and to pass on their value to the public, work which should be easy and which should be productive of authoritative results considering the eminent men who form the association. Carrying the idea still further, the Chamber will undertake to find capital to produce and market devices which in its opinion are meritorious. Weekly meetings will be held when inventors will be permitted to offer their ideas for opinion, a small fee being charged for the service. If, in the opinion of the Chamber the invention seems promising and the inventor is desirous of placing it on the market, the Chamber will undertake the work, and will also act as estimate of cost to the inventor.

## Correspondence

### Lighting Buoys with Selenium Cells

To the Editor of the *SCIENTIFIC AMERICAN*

It has just come to my notice the letter of Mr. A. K. Sloan in the June 7th issue of the magazine, on automatic lighting of lights buoy by means of selenium cells, of which he suggests the use of the selenium cell to control the buoy.

The controlling of buoys by the selenium cell is by no means new, as this has been manufactured by Ernst Ruhmer, and has been in operation on the Baltic Sea for many years. This has been described in Mr. William J. Hammer's book on selenium, etc., and also in a recent article on selenium by Dr. Hansmann in the recent issue of the *SCIENTIFIC AMERICAN*.

It has been rumored that it might be adopted for use in the Panama Canal. I should think that Mr. Sloan is behind the times.

### Raising a Wick Evenly

To the Editor of the *SCIENTIFIC AMERICAN*

I attach herewith the drawing of an arrangement I have devised for raising the wick or wicks of an oil cook-stove straight. In the years during which I have used oil cookers, it has been my experience that after a short period the old-style ratchet spindle refuses to raise the wick evenly. One end is invariably raised higher than the other, and any pan or other kitchen utensil placed over the flame has its bottom covered with an extremely oily soot.

Device for raising a wick evenly.

To obviate this trouble I suggest the ratchet wheels be put on a double spindle, those near the front to be put on an outside or sleeve spindle, and the rear ratchet wheels being placed on a spindle running through the "dove" and extending the entire width of the work tube. With this arrangement it is possible to raise one end of the wick independently of the other, thus adjusting the wick to give an even flame.

### Price Maintenance and the Dealer

To the Editor of the *SCIENTIFIC AMERICAN*

We consider the action of some merchants (jobbers and retailers) in deliberately cutting the standard fixed prices on nationally distributed articles as absolutely unfair and unjust to the producer. It requires a long time and the expenditure of a great deal of money to establish a national demand for any manufactured product. And such demand can never be created or maintained except the product is of the highest merit. Instead of understanding the progress made by the producer through price cutting, the dealer should welcome an established, fixed selling price, alike to everyone, thereby assuring to himself a living margin of profits in handling such a product.

I trust that through your campaign, the public may come to view this proposition in its true and proper light.

### Our Poor Maps

To the Editor of the *SCIENTIFIC AMERICAN*

What you have to say regarding map-making and publishing in this country is woefully true, and I have been swindled out of my money many times before I learned to look abroad for maps that are completely honest.

Because it is not so much the fact that his maps are doctored out of date that marks the American map-publisher as lacking in enterprise and self-respect, but it is the unreasonable dishonesty of paining off old maps for new that puts large publishers in a class with false fire-insurance companies.

I have often paid several dollars for a map bearing a recent date, to find it lacking in ten years old information, to find that the old date had been scratched off the plate and a new date fraudulently inserted. Think of such a business truck in the great and noble art of map-making.

As I am on a geographical subject, I wish to point out a hoary, seemingly needless inaccuracy, which crops out in the article "Solving the Latitude." The writer mentions "The Barbados" and shows the current name is "Barbados" pure and simple, being a single island of the West Indies, not a group of islands as many people seem to believe.

### Controlling the Mississippi With Small Dams

To the Editor of the *SCIENTIFIC AMERICAN*

I have followed with great interest the article which you have published concerning the recent floods in this section of the country. In all of the above I have not read of a single plan that looks promising for handling the method of controlling to avoid future damage from great floods by building mighty dams and have great reservoirs impound the water does not seem wise or economical. It would require the condemnation of immense tracts of land that are too valuable to be given simply for the storage of waste water. Then too, there would always be the danger of some of these dams bursting, and with the great amount of water back of them, would at various times do much damage in the valleys farther down. And this is the very danger we want to avoid.

As our civilization progresses, and our farm lands become more and more improved, thing is done and the water rushed into the streams and rivers, with the resultant flood. The National Government must interest itself in preserving the life and property of all the people, both up stream and down, and just how best to do this is one of the greatest conservation problems before it. As the reservoir plan is unsafe and undesirable so, too, the suggestion that the country be reflooded is untenable, it will never be done; it is too good a process, would require too great an outlay of public funds and use up lands that cannot be spared. Then too, the project of widening all the streams will not solve the problem, as that will only aid in carrying off water from one place to make it worse in another.

There is a plan however that will do the business, and at no great expense, that will not cause a lot of the best land to become mere swamps, mosquito-breeding reservoirs. This plan is to have the Federal Government rent or buy the flood lands along all the upper streams, run, creeks and rivers, and at appropriate places build small dams with dikes and flood gates to hold back the water to a height of from five to ten feet. These dams can be made at a very small outlay as compared to the large dams for permanent reservoirs.

Then, whenever there is a storm, let the gates be closed and catch the water in the basin thus formed until the dam overflows. After a week or two, once after another of the gates can be opened and allow the water to drain off. The holding back of the water in these small dams will prevent the fertile deposit of silt to be dropped on the flood land that will greatly improve it and not retard the farming interests in the least.

A thousand such dams throughout Ohio during the recent floods would have saved many times their cost in life and treasure.

The flood lands by this plan can be used every summer for raising crops, whether owned by the Government or individuals, and much of the poor, stony gravel patches found in bottom lands to-day, because of the rapid wash of streams, would disappear and become covered with the finest kind of soil.

During the late flood the writer saw the rapid current of a stream—usually nearly a dry bed—wash away forty feet of the bank which had been under cultivation for years. The great damage was done when water backed up by a railway bridge broke loose, and all came down the stream at one time. This stream could easily have been controlled by dams as above described.

By having small and numerous dams this danger of a great rush of water is remedied, for even if one or two should break down, it would have little effect, as there would be other reservoirs to catch and hold the surplus water.

The writer claims for the small dams greater safety economy in construction, maintenance, increased value in abutting property, and consequent increased production for the State, and less chance for graft in their construction. This last feature might be objectionable to many of the Government experts, but it is worthy of consideration by the layman.

Fredericktown, Ohio.

## Melting Metal Under Water

By the Berlin Correspondent of the Scientific American

THE cutting of metals under water has entailed great difficulties and enormous cost, the tools and apparatus available for this purpose being utterly inadequate. Apart from the diver's hammer and chisel, compressed air chisels, and, for certain operations, circular saws driven from above, were used in this connection.

While the scope of circular saws is extremely limited, compressed air chisels are quite suitable in most cases, though, of course, the exceedingly high cost and slowness in operation are serious setbacks of this process. These conditions suggested the use of autogenous metal cutting for submarine work. As the hydrogen oxygen flame would be immediately extinguished, when immersed in water, the customary process could not be used. A German engineer, Mr. A. Hecht of Kiel, however, designed a bell-shaped burner head which being secured on an ordinary (Grisolben) burner, allows the flame to continue burning below the water, thanks to a supply of compressed air. This patented process has now been so improved by extensive experiments, that the cutting of metals under water is effected about as quickly as above the surface. In fact, the new tool is said to be ideal in every respect, avoiding as it does the drawbacks of the compressed air chisel, while working extremely rapidly and accordingly most cheaply, and lending itself for use in the most varied applications.

The new process can be used in cutting through iron pile pinnacles and all sorts of iron structures, cutting up iron or steel beams or preparing them for blasting, clipping rivet heads, welding loose rivets, drilling holes, etc. The rate of working is at least twelve times as great as that of compressed air chisels, which accomplishment is bound to prove of immense value in clearing waterways of wrecks and other obstructions interfering with navigation.

At a test recently made of the new apparatus at Kiel harbor before some prominent engineers and representatives of the Emperor William Naval Department and several berthing companies, an iron plate of 100 by 20 millimeters in an exhibition tank filled with gas was bored and cut through about 10 centimeters in length by means of the oxygen-hydrogen flame. A diver then went down into the sea, to about 5 meters depth and after boring a hole into a 60-millimeter square iron, cut through the iron in about 30 seconds.

An iron sheet, 20 millimeters in thickness was then drilled through and cut in 10 seconds, to about 30 centimeters' length.

## Raising the United States Brig "Niagara"

By W. L. Morrison and A. G. Kessler

THE *Perry Centennial* to be celebrated from July to September will be as memorable to history as the famous battle in commonwealths of which it is to be held. Perhaps the most interesting feature of the Centennial will be the reconstructed brig "Niagara"—Perry's second flagship, which is now at last ready for launching.

Before going into the details of this interesting and historic work, it may be well to acquaint our readers of the important facts relating to the battle of Lake Erie. It is possible, of course, in this article, to give only the briefest outline of this memorable fight, and those who are interested, can secure further details from all of the standard books of American history on the War of 1812.

It was during the early summer of 1813 that Lieut. Oliver Hazard Perry, then a young man of twenty-seven, succeeded against incredible odds in building and getting together in Presque Isle Bay (Erie, Pa.) some nine ships, which number formed his entire squadron during the famous battle which was to follow. The two largest and most heavily armed vessels were the brigs "Lawrence" and "Niagara," following these was a smaller ship, the "Chalcedon," and six small schooners. The "Lawrence" was chosen by Lieut. Perry as his flagship, and it was she that bore the brunt of what was practically a

hand to hand conflict, until so disabled it was necessary to abandon her.

The squadron was hardly completed when it was found that the British fleet was in waiting and ready to strike at any minute. The channel of Presque Isle Bay (leading from the bay into Lake Erie proper) was not very deep, and although the smaller vessels

Autogenous metal cutting tests in experimental and demonstration tank.

could readily get out of the harbor, it was with considerable difficulty that the "Lawrence" and the "Niagara" were moved over the sand bars in the channel. In fact, it was necessary to take off the armament and raise these vessels by means of pontoons placed on either side so that they would clear the channel.

The British fleet was in sight even during these operations, and consequently when Perry's squadron had hardly cleared port, the preparations for the battle were on in deed earnest—the actual fight occurring about

one month later. After some unprofitable shelling, the enemy fleet was on September 10th, 1813, at Presque Isle (the main landing), Erie, Pa., where the memorable "battle of Lake Erie" took place.

The British fleet consisted of two frigates, "Huron" and "Queen Charlotte," accompanied by five small armaments (although somewhat superior) to the "Lawrence" and "Niagara"; the "Lady Proctor," captain in the American ship "Chalcedon," and three small schooners—six in all. It is quite true, therefore, that the American vessels were not only more numerous (five to six), but they were also more powerfully armed individually.

It would be needless for us to attempt to give the details of the battle, as this is fully and minutely described by many of our able historians. The story remains, however, that the "Lawrence" was soon in the thick of the fight and borne down upon so heavily by the enemy that she was disabled and almost totally disabled. Perry consequently transferred himself and his few remaining officers and crew in an open boat to the "Niagara," then in command of Lieut. Elliott. The "Niagara" immediately became the flagship, and with her the battle was finished and the British squadron completely defeated.

After the battle, Perry sent his famous message to the Navy Department, which is quoted as often as Caesar's "Veni, Vidi, Vici," and which conveys much the same meaning, "We have met the enemy and they are ours."

There is just one more interesting feature which can hardly be omitted before giving the actual details of the raising of the "Niagara," and that is the controversy which arose between Lieut. Perry and Lieut. Elliott. It was claimed that the "Niagara" did not give the "Lawrence" proper support during the battle and many assigned this as the cause for the "Lawrence" being literally cut to pieces so early in the fight. Perry himself preferred charges some years after the battle which would have resulted in the court martial of the "Niagara's" first commander, had not Perry died before the trial was to come off. Perry's officers and men stood by him, and Elliott's officers and crew stood by their superior all through the controversy. The result was that many an interesting street fight took place in Erie during the years following the battle, between the crews of the two ships, and it is said that some of these "scrapes" rivaled the famous battle itself.

Two years after the battle of Lake Erie—July, 1815—the "Lawrence" and the two British ships, "Detroit" and "Queen Charlotte," were captured and by the Navy Department in Milsby Bay (a small bay and a part of Presque Isle Bay, Erie, Pa.), while the "Niagara" was retained for some years as a receiving ship. The "Lawrence" was again raised in 1870 and sent in sections to Philadelphia for the Centennial there. The building in which she was housed during the exhibition, outside of the exhibition grounds, was destroyed by fire during the Centennial, and all that was left of the old battery was burned.

As the "Niagara" is really the ship on which our article hinges, we will therefore omit further details concerning the other vessels and confine ourselves only to this ship.

The "Niagara" was also given her final resting place in Milsby Bay in the year of 1822 within a short distance from where the "Lawrence" lay. It was at the suggestion of Lieut. W. L. Morrison of the naval reserve of Pennsylvania that the Perry Centennial Committee first considered the advisability of raising the remains of the famous brig, and this was consequently begun in the fall of 1913. Omitting for the reasons we set out the work began at once.

The old ship was covered completely with some six feet of sand and lay in about twenty-five feet of water. During the fall season a sand pump was used to remove the tattered hull, and when this had been accomplished the actual raising was begun. Four heavy chains were secured to the hull, and the work in the adjacent water. Two pieces of steel pipe, each placed at an angle and supported by a pump driven by a gasoline engine, of approximately 100-horsepower, were used to raise the ship. A

The top picture represents the "Niagara" as she appeared in 1813. Above the picture are shown how sand and mud were blown away from the gunbarrels, how the hull was raised, and how the hull holed after having been lifted out of the water.

Raising Perry's flagship "Niagara."

# Sand Dunes

## How They Are Reclaimed in Europe and in the United States

An active dune covering brush land.

THE best example of the complete reclamation of shifting sand areas is in Gascony on the west coast of France. In the beginning of the nineteenth century this extensive plain was still a sandy desert, but to-day it is through the work of the French Government, covered with a well-managed pine forest, which supports a large population. Large areas of the Coastal Plain of the United States are covered with enormous dunes, which continually move inland. These gigantic drifts of sand pile up high, covering fences, farm buildings and often vast stretches of valuable timber in their line. In many places large farms are being buried underneath the sand. Along the Great Lakes entire orchards are smothered, railroads covered up, and extensive areas of arable land made desolate as a desert. Along the eastern coast of the United States from Cape Cod, Massachusetts, to Miami, Florida, hundreds of thousands of acres of barren sand hills greet the eye. Some are perched high on bluffs, others creep down to the water's edge. Years ago most of this stretch of sand land was covered with forests. Man removed the timber, fire after fire followed him, and the sand, which nature had expended centuries in reclaiming, was once more loosed and drifted about by the wind. Thus large areas in the United States are rapidly approaching the former condition of the Landes of Gascony, where 600,000 hectares of sandy moorlands were made productive by properly controlling the shifting sands along the seashore. The success of the work in Gascony has given assurance that similar results may be attained here, provided proper methods of planting are followed.

In France the fixation of these sandy barren wastes was started by constructing a littoral dune along the seashore. This dune was the secret of the success in the work. It was simply a bank of sand of certain dimensions, which served as an obstruction to the sand which came from the ocean. On top of this low bank of sand was erected a hurdle to check the sand in its forward movement and in this way the height of the littoral dune was increased. When the first hurdle was covered up another was put in its place, and still another until the dune was about 25 feet in height. This dune, which was about one to two hundred feet from high tide mark, protected the vegetation on the leeward side of the dune from the ocean winds and made conditions favorable for the growth of trees and other vegetation. The surface of the sand was covered with brush arranged like the shingles on the roof of a house. The brush was tied into bundles of about 10 inches in diameter and these were held in place by a few shovelfuls of sand here and there. The seed of beach grass (*Ammophila arenaria*) was then scattered among the brush and it soon sprouted and held the sand in check.

While this system was effective it had to yield to a newer, quicker, and cheaper method. The formation of the littoral dune is a very slow and expensive undertaking and it has been found that this may be edited by planting the windward side of existing dunes with beach grass or any other form of vegetation that is able to grow in the particular location. It has been successfully proven that the seed of beach grass and other plants will grow on sand and will be

carefully controlled by artificial barriers such as fences of boards (hurdles) or brush.

They serve to check the advance for a time, but later they are covered and rendered useless. Permanence of the sand can only be secured by a forest cover. The building of fences and covering the sand with brush, debris, or manure must be followed by planting or sowing grasses and setting shrubs and trees. Beach grass is able to withstand the action of the sand and wind, especially when it is planted sufficiently close

An ineffective method of controlling shifting sand along the Oregon Short Line (Columbia River), Washington.

An effective method of controlling a dune threatening railroad property

Reclaiming a sand dune by planting beach grass.

together. If this method is followed the use of brush will be unnecessary. It has risings many feet long by means of which it fixes the sand. The grass continues to grow and to develop new roots and increase in height as the dunes become higher. Whenever a patch of beach grass takes root there the sand blown from the region of greatest supply matters around it. As the sand spreads, the grass grows through it until the hard, dry blades form the nucleus of thousands of tons of sand. The beach grass is the best among sand-binding plants and is used extensively for this purpose. The chief characteristic of this plant is that when the sand tends to cover it up its height growth is stimulated in order to keep its tip above the sand. The house of beach grass is along the Atlantic Coast, but its artificial range has been considerably extended. It is now one of the principal sand-binding plants in Europe and also on the Pacific Coast. Other grasses suitable for planting on the dunes are wild rice (*Sigmo arenaria*), bitter grass (*Panicum amarum*), sea oats (*Uniola paniculata*), and blue-joint grass (*Calamagrostis* sp.). All these grasses possess special merit as sand-binding plants, and can be used to advantage within their region of growth.

The reclamation of the sand dunes along the Atlantic Coast has been suggested and advised, but only in a few localities have these plans been put into actual practice. It is possible to control these shifting dunes.

When nature reclaims a sand dune grasses are the first plants to make a start. These are followed by shrubs and later by trees. For a plant to live and thrive in shifting sand, it must have the power to grow upward as fast as the dune increases in height or to follow the sinking sand when it decreases in height. It must spread by means of underground stems, and must be a perennial. These conditions are not most successfully along the Atlantic Coast by beach grass. Certain shrubs meet the requirements for binding sand almost as well as some of the grasses. Among these are the native willow, wax myrtle, and cherry and holly. Grasses are the first plants on the dunes in the natural process of reclamation and by means of these the movement of the sand can easily be stopped. After this is accomplished shrubs and trees should be planted. While the wax myrtle and sand cherry are good sand binders they do not produce useful wood. The willows and poplars are very valuable in reclaiming dunes and their woods have commercial value. The holly is very easily propagated and grows under adverse conditions. It forms an excellent shelter, and produces a clean white wood, which is used for a good many purposes and can be recommended for planting. The black locust grows in poor soils and is used in Europe for planting reclaimed areas. It also produces a valuable wood and the tree reproduces itself very freely, which is an important consideration in the management of the plantation. The pine is diametric to the region of the dunes are best suited. In New England the white and pitch pine will thrive on sand land after it is fixed. In New Jersey the pitch pine is well adapted and further south the lobloby pine will make a good growth even on the exposed places.

# The Heavens in July

## How the Navigator Lays Out His Course

By Henry Norris Russell, Ph D.

THESE words are written in the luxurious library of a modern Atlantic liner. If the hundreds of passengers on board one may wonder how many have any realization that the speed and accuracy with which the great ship finds her way across the trackless ocean really depends entirely upon astronomical science.

Navigation—the science and art of determining a ship's position, and laying out her course—in its narrower sense is but the smaller part of the art of sea-manship, but it is an essential part of the art in itself, it is as much a branch of astronomy as of nautical learning. The mariners of early days never willingly ventured out of sight of land. In the days of the *Florida* can trade to England for its ships doubtless skirted the northern coast of France, far up the Channel until the chalk cliffs of England actually came in sight to the northward, then only did they dare to cross the narrow seas, and coast slowly along the British shores to their destination.

We need not cast any imputations on their courage for this lot of a ship blown off to sea out of sight of any landmarks, in those days when there was neither chart nor compass, must have been at most desperate. Their only hope must have been of clear weather, so that their sails lay a course with the aid of the sun or stars, in the general direction of the land, with hopes of finding some haven of refuge before their food and water gave out.

Things are indeed other wise to-day, but why can the modern mariner sail out confidently into any sea sure that he can tell where he is, even at the end of a long voyage, with in a few miles at most, as long as he can but have a few clear glimpses of the sky? A few simple instruments, whose cost is the modest trifling compared with that of the smallest of sailing vessels, make the difference. No sane man would put to sea without a compass, a sextant, a chronometer, and the *Nautical Almanac*, and these are all he needs.

At the risk of telling an old story to some readers, let us consider how these instruments are used to find a ship's place. What the captain wants to know are his latitude and longitude. To find the former is a very easy matter, but the determination of longitude at sea has been one of the great historic problems of applied science.

A moment's consideration will show why the second problem is more difficult. Latitude can be determined by observations at a single station, but we can find our longitude only by determining the time of day at our own position (which is easy) and the time at Greenwich at the same instant (which is a far harder thing to do).

The character of the observations which can be made at sea is strictly limited by the peculiar conditions. No fixed instrument can be used on a rolling deck, all measurements must be made with apparatus that can be held in the hand. This practically confines us to the use of the sextant, with which one sights on the sun and the sea horizon at one and the same time, makes the fringe of the sun seem to touch the horizon, and then reads off at once the number of degrees (and fractions of a degree) which the sun appears to be from the horizon—technically, its *altitude*.

Any intelligent student, on land, or even in perfectly smooth water, can learn in an hour or two to make such observations with an error not exceeding a minute of arc (corresponding to one sea mile on the earth's surface). To get the same accuracy when the observer's footing can be maintained with difficulty on the deck of a vessel plunging in a high sea demands a degree of skill and dexterity for which those of moderate experience have the most lively respect.

Granted, though, that we have learned how to find the sun's altitude (and, incidentally, to apply several necessary corrections to the crude observed value, and get an accurate result), what good does this do us? Let us first consider our altitude. If we were on the earth's equator, the equator in the sky would pass right overhead, that is, its highest point would be 90 degrees from the horizon. If we were at the pole, the

and taking the biggest one. To get our longitude we must do two things. First, find out local time and the Greenwich time at the same moment. The former is a matter of observation. If we know our altitude, it is an easy matter to calculate just at what interval before or after noon the sun will be at any assigned height above the horizon (how that is explained later). We have only to measure the altitude, and may then calculate the time by straightforward trigonometry. This observation should not be made near noon, for even the sun's altitude changes very slowly, and a very small error of observation will lead to a large error in the calculated time. By observing about 9 A. M. or 3 P. M., when the sun is rising or sinking rapidly, much more accurate results can be obtained. There is no great trouble about this, though it appears to be a rather a much more difficult problem than the determination of latitude. With the aid of a table of logarithms and the *Nautical Almanac*, a practical worker can solve it in a few minutes. To be sure, he must know his latitude, but the captain always knows this with sufficient accuracy by means of his "dead reckoning" of the distance and direction which the ship has run since the last observation was made.

The real crux to the problem is to find what was the Greenwich time at which the observation was made. Now this is no simple enough. Every ship carries at least one good chronometer keeping Greenwich time. The observer needs only to read the time by this chronometer at the moment when he measures the sun's altitude, and then, if he knows how much his chronometer is fast or slow, he has the Greenwich time. Then the difference between this and the ship's time gives him his longitude.

But to find the error of the chronometer is the real problem. At the present day a good instrument, carefully handled, is an entirely satisfactory for any voyage of two weeks' length or thereabout. Every day that the ship is in port, some officer will watch the fall of a time-ball, dropped just at noon, by which connection with some observatory, and so find out the error of his chronometer (how much it is fast or slow) and also its rate (how much it is running fast or slow per day). But the "set rate" of a chronometer may not be the same as the "whole rate," but a little faster or slower. When a ship has been out a month or more the chronometer may not be running at the same rate that it did in port, and a steadily increasing error will result.

Now we cannot see the equator, but we can observe the sun—and the *Nautical Almanac* tells us just how far the sun is north or south of the equator every day, for example, to-day (June 2nd) it is 20 degrees 9 minutes north of the equator, so when the sun seems highest on the sky, the equator will be at just this distance below it (else our ship is in a northern latitude). If then, for example, the sun at its highest point in the sky, at noon, is found to be 65 degrees 37 minutes above the horizon, the celestial equator must be 45 degrees 35 minutes above the horizon. Subtracting this from 90 degrees, we find that our latitude is 44 degrees 55 minutes.

THE HEAVENS IN THE REGION OF HERCULES

celestial equator would run all around the horizon—its altitude would everywhere be 0 degree. It is easy to see that in other latitudes—for example, 30 degrees north of the earth's equator—our zenith (the point right overhead) would be 30 degrees north of the equator in the sky, and hence that the highest point of the equator would be 70 degrees from our horizon.

Now we cannot see the equator, but we can observe the sun—and the *Nautical Almanac* tells us just how far the sun is north or south of the equator every day, for example, to-day (June 2nd) it is 20 degrees 9 minutes north of the equator, so when the sun seems highest on the sky, the equator will be at just this distance below it (else our ship is in a northern latitude). If then, for example, the sun at its highest point in the sky, at noon, is found to be 65 degrees 37 minutes above the horizon, the celestial equator must be 45 degrees 35 minutes above the horizon. Subtracting this from 90 degrees, we find that our latitude is 44 degrees 55 minutes.

All this is very simple, and requires nothing but the sextant and the *Nautical Almanac*, for the greatest altitude of the sun can be found simply by making several measurements, beginning a little before noon,

# Some Suggestions for the Handy Man

By Henry Kleis

**Repairing a Leaky Kitcher Boiler.**—A leaky kitchen boiler was recently repaired by the writer in the following manner. First the water was drained off and then the holes were carefully enlarged by reaming them with the tang of a file until they were large enough to receive a small stove bolt easily. The hot-water pipe was then disconnected from the boiler and bent slightly to one side, as indicated in Fig. 1 of the accompanying drawing. A stout piece of thread, to the end of

Home repairs of a leaky kitchen boiler

which a wire nail was secured as a weight, was then lowered through the hole in the top of the boiler. By means of a wire hook the thread was caught and pulled through the pipe opening in the side of the boiler. The wire nail was then disconnected and, instead, a stove-bolt with a washer on it was tied in the thread and pulled carefully through the hole in the top of the boiler. In this position it was held with a knife blade pressed against it until the thread was disconnected and a leather washer, metal washer and nut could be screwed down on the projecting end. The bolt was long enough to permit of its being gripped with a pair of pliers and held firmly while it was being turned up with a wrench (as indicated in Fig. 2). The other hole in the boiler was in the side, near the top. Hence the same method was pursued, except that a piece of wire with an eyelet at the end of it was used. Through this eyelet the thread was passed. The wire kept the thread away from the side of the boiler, so it could readily be hooked and brought through the opening in the hot-water pipe. After several days of use it was found that the water was leaking again, because the leather was rendered brittle by the heat. The work had to be done over again, but in place of leather, washers were made out of electric splicing tape or tire tape, bending a piece back and forth on itself six times and making a hole in the middle with two cross-cuts. In a similar way a long loop in the top of the boiler was mended by using a piece of brass with a washer of tire tape and fastening it in place with two bolts.

**To Prevent Rusting of Tools.**—The writer found himself in Florida a few years ago, where he experienced much trouble from rusting of his tools on account of the very humid climate. The difficulty was overcome effectually as follows. Along the top of the tool chest a strip of flannel was tacked, as shown

Rust-proof tool chest.

in the sketch, so that when the cover was fastened down it made the chest practically airtight. Then a large cigar box was procured and fastened inside the tool chest. The box was filled with unsalted lime. The cover was left on the cigar box, and always kept open except when the tool chest was moved about when, of course, it was closed to prevent spreading the lime.

**Attaching Guy Wire to Smooth Pipe.**—Many wire-rope hoistmaster snafus have stemmed from difficulty in trying to attach the heavy guy wire directly to the smooth galvanized iron pipe mast which is frequently employed as a support for the aerial wires. In order to preserve the full strength of the mast it is, of course, inadvisable not to drill any holes or cut any grooves in the mast where the wire is to be joined. The writer

recently found himself up against the same problem, and solved it in the following manner: The guy wire was first wound three times around the end of an iron bolt near the head, then twice around the pipe, and then three

Attaching Heavy Guy Wire to Smooth Pipe.

times around the bolt again at the other end. The nut was then tightened up slightly so as to hold the wire in position while the other ends were anchored, and when this had been done it was screwed up tightly, and the projecting end of the bolt cut off.

**Removing a Revolver Barrel Without a Wrench.**—Recently the writer went on a hunting expedition to the Far West, in the heart of the Rockies, to a place over a hundred miles from the nearest railroad station. Our guide had a revolver in which the barrel was worn out from much shooting, and as there were no gunsmiths handy, we went to the factory for a new barrel and then without tools we proceeded to remove the old one and substitute the new one in the following simple and satisfactory manner. A stout piece of rope was first procured, and one end of it securely tied with three to the muzzle of the barrel. The rope was next wound tightly around the barrel to its full length and then around a steel bar, as shown in the sketch. A piece of square oak about 1½ feet long was next introduced into the frame, from which the cylinder had

An improvised pipe wrench

been removed, and then pressure was exerted on the steel bar and the oak stick in opposite directions, but without results, as the barrel was seemingly rusted in tightly. The rope was then removed, the barrel heated and plenty of oil run around the thread where it screwed into the frame. After this had been done and the barrel cooled down it was tried again, and this time it was unscrewed quite easily.

The new barrel was then screwed into place as far as it would go by hand, and then wound with tape to protect the highly polished blued surface from being scratched. The rope was then fastened and wound around as previously described, and then turned up tight into the frame. The revolver has had hundreds of shots fired from it since then, and found to be as satisfactory as though fixed up by an expert gunsmith.

## Some Automobile Repairs

By F. C. I.

THE following are a few repairs made by the writer which he believes he can do to the owner of an automobile. If he does not wish to do the work himself he may hand the suggestion on to his repair man.

**Tightening a Loose Automobile Wheel.**—In the older models of automobiles, many of which are still in use, the rear wheels are held to a straight axle. This gives rise to much trouble, for if the wheel once becomes loose, it soon works the key back and forth, wearing the key seat and shaft to such an extent, that it is almost impossible to tighten the wheels securely. The best way of overcoming this difficulty is as follows: The two halves of the axle are removed and the splines (A, Fig. 1) are tapered in the lathe for the full length

of the wheel hub, making them a quarter of an inch smaller in diameter at the outer end. A bushing B is made to fit the wheel and is bored out to the same taper as the splines, but is made about an eighth of an inch longer than the splines. The old keyway in the splines is then trued up and made deeper and a new key is fitted into it. A slot is cut in the bushing on a shaper or with a hacksaw, which allows the bushing to be slipped upon the splines with the key in place. The ends of the splines are bored out and tapped to receive cap-screws C. A washer D is made of the size of the hub flange, and with a hole for the screw C. The bushing and wheel are slipped in place and the key is driven home. The slit bushing is forced in and held in place securely by the washer F and screw G, while its tapered surface wedges the wheel securely to the splines and keeps the wheel perfectly true. The hub cap covers all. If the bushing B is too short a split washer O may be added.

**Lengthening a Valve Stem in a Motor.**—Valve clearances are caused by too much space between the valve stem and its lifter, a sharp metallic knocking results as the lifter hits the stem, and also as the valve

Fig. 1—Method of tightening a loose automobile wheel

head hammers the valve seat on its return. The valve lift rises more slowly at first than later, hence the advantage of as little clearance as possible, for besides allowing the lifter to compress more gently in contact with the stem, the valve head is forced to move more slowly as it approaches its seat, hence its seats gently. It will readily be seen that for quiet running, assuming the same seat to be worn and of the proper contour, this space should be reduced to the minimum. Too much space results often in loss of power. The thickness of a visiting card is about right for some even a little less for others, depending on the expansion of the stem from the heat of the engine. Some engines are not provided with means for adjusting this clearance. An easy and entirely satisfactory method of reducing this space in such a case is as follows:

An empty brass cartridge of almost if not quite the proper size to fit the valve stem is easily secured. A punch is driven into the cartridge to strain it toward the end. If the cartridge is a little too large and its loose, place it upon a hardwood peg and crimp it in three or four places with a chisel, as shown in Fig. 2, or reduce it to proper size with a tap wrench. It can now be forced on the stem. Fig. 2—Improve and will stay in place. File off the vised thimble end of the cartridge until there is for a valve sufficient space. If this space closes when the cylinder gets hot, file off just a little more. The engine will tell you by refusing to go or stopping when the cylinder heats that more clearance is required. The cam positively soft metal of the cartridge has a cushioning effect which also does much toward eliminating this unpleasant knocking.

**Emergency Repair for a Roller Bearing.**—Recently one of the spiral rollers in a flyball bushing in an automobile bearing was broken near the outer end and the piece caused trouble by becoming jammed, crossed, with the obvious danger of overheating the bearing. No new bushing of proper size was at hand and the repair was made by inserting a small rod through the roller and driving each end. The temporary repair was made to prove permanent, as the owner of the car has never called for the new part which was ordered.

Fig. 3—Repair of a roller bearing

### Electric Batik Work

By Dr. Alfred Gradewitz

**B**ATIK work has been practiced since time immemorial by the natives of Java, and consists of producing patterns by means of liquid wax on a bright fabric paper or the like, which is eventually dyed.

Electric Batik pencil in operation.

Such parts of the fabric as correspond to the pattern were first covered with hot liquid wax, the whole is dipped into a dye-stuff liquid, when the covered portions will take on no dye, whereas the remainder is dyed uniformly.

Specimens of Batik work.

After drying, the same fabric (which is now multi-colored) can again be covered with a pattern which, by the batik process, is preserved in the former color, while the background takes a darker hue, and the same operation can be repeated several times until the background has become very dark.

After removing the wax by washing the whole piece of fabric with gasoline, the various colors are brought out most effectively on the dark background. Wonderful color effects are thus obtained, such as can be insured by no printing process, the fabric being permeated entirely with color, which is best appreciated on holding the fabric against the light.

The possibilities of batik work are by no means so limited as would appear at first sight. The same process can, in fact, be applied to wood stained in several hues (or overwaxed), as well as to metal dyed or etched by chemicals. Especially beautiful etchings can thus be produced on copper brass, etc.

The instrument used by the Japanese in applying the wax is some sort of small funnel fixed to a handle with a fine opening in which the wax is heated over a coal fire. Similar attachments, or else closed reservoirs terminating underneath in a point and a small opening are used in Europe where batik work has been introduced. In connection with all these devices the wax must however be reheated from time to time (over an alcohol, gas or gasoline flame), and it cools rapidly during use. This lack of uniformity in the temperature of the wax, of course, entails a number of drawbacks, while the liquid wax immediately after heating flows out in a very energetic jet liable to produce too thick lines or even blobs, the outflow soon becoming very spurring, as

the wax cools down. In order to insure an absolutely uniform temperature of the wax, a German lady, Frau Gertrud Langschütz-Jeweleit of Nuremberg, has devised an electrically heated Batik pencil. Apart from uniformity in the thickness of lines, this insures a considerably more rapid work (the continual reheating being dispensed with) and far greater ease and accuracy.

The electric Batik pencil is a cylindrical wax holder to the lower part of which is screwed a mouth-piece with a fine bore. A fine sleeve placed in the wax holder above the mouth-piece will retain any impurities of the liquid wax.

The wax is heated by the heating coil the lead of which passes through the handle, being connected in its interior with a flexible cord by means of which the Batik pencil can be joined up directly to a contact box for 110 or 120 volts (or through a series resistance to higher tensions). The Batik pencil can be used with continuous as well as alternate currents, its consumption being about the same as that of a small or medium-sized incandescent lamp.

### An Iceberg Indicator

**P**ROF HOWARD T. BARNES of McGill University, Montreal, Canada, has blazed the way in the study of the detection of large bodies of ice through the reading of the temperatures of the sea water at a distance from the source of chill. For this work Prof. Barnes has employed a microthermometer capable of registering variations of a thousandth of a degree Fahrenheit, and his researches have given to the subject a new significance.

Following the loss of the "Titanic," the United States Naval Authorities maintained for some time an ice patrol service in the mid-Atlantic, two of our scout cruisers having been detailed to alternate on that duty. Interest is now revived because of the Government's intention to renew this ice patrol in the coming season of greatest danger. These vessels can only maintain surveillance over a limited area, and there is every reason why such sea-going steamers traversing the North Atlantic should have their own means for certainly detecting the proximity of ice.

Many clever minds have given a good deal of study in the past months to the devising of instruments for this service, and certainly there is a need for some apparatus which can be relied upon, especially when approaching and passing through the waters south of Newfoundland, where confusion is engendered by the continual conflict between the Labrador current and the Gulf stream.

The prime desideratum is an instrument that will work at all times, one upon which the navigator can confidently depend.

With this latter and essentially practical aim in mind, Mr. William H. Bristol has worked out his detector, and the ingenious instrument promises to fill a want of long standing. The apparatus is functional very simple, and its arrangement is such that its

1 and 2 are dissimilar metals forming the elements of a couple, 3, the point where the elements join. This is the active end of the couple, 4, 4, the insulated ends of the couple, 5, 5, openings to the sea, which may be closed if the couple be in touch with the metal sheaths 10, 6, 6, the circuit connecting with the alarm system 7 and the recording mechanism 8, 9, the outside or bottom plating of a ship.

The thermopile, placed below water in contact with the sea, records changes of temperature.

Stems for duty or its working order can be quickly determined at any time. The navigator cannot afford to trust to facilities which are uncertain in their functioning, and this has been the ruin of more than one cleverly-designed mechanism. The Bristol detector is based upon the well-known phenomena of the thermoelectric couple. For the sake of those that may have forgotten their school-day physics, let us explain briefly.

Two hair rings of dissimilar metals when joined together and either suddenly heated or chilled at one of these connecting points, give birth to a feeble current which will flow until the opposite junction has acquired the same temperature. The sensitiveness and the potential of a thermoelectric couple depend upon the character of the two associated metals. The strength of this current can be increased by employing a number of couples, and a group of these bound for a single service is what is termed a thermopile. In order to get a sufficient electric impulse, Mr. Bristol uses a thermopile which is suitably placed below the waterline of a vessel and installed where it will feel quickly delicate differences of temperature in the swirling water. It is not necessary to expose the thermopile directly to the water; the desired effect may be obtained by having the ending end of the thermopile in contact with the outside plating of the ship or with the inner side of a protective sheath which is in touch with the sea.

Simple as this device is, the entire apparatus of the electric indicator was tested upon the "Titanic" and was found to be of great value in detecting ice.

A, thermopile; B, mechanism operated by current from thermopile. This mechanism opens and closes the circuit functioning the bells and lights U, D, S, and P; C, recording mechanism which shows the height and character of the temperature change; D, the battery of the operating relay; E, testing bulb.

A device for detecting icebergs at sea.

## The Motor-driven Commercial Vehicle

This department is devoted to the interests of present and prospective owners of motor trucks and delivery wagons. The Editor will endeavor to answer any questions relating to mechanical features, operation and management of commercial motor vehicles.

### Logging With a Motor Truck

**M**OTOR trucks occasionally invade the forests and bring out loads of timber but rough logging is a branch of the lumber industry in which little is heard of the motor truck. While the logging locomotive is probably immune from any trouble upon its usefulness by gasoline trucks enough progress has been made in gasoline logging to promise a wide field of activity and warrant serious consideration of the power truck from the standpoint of what it has actually accomplished. A five-ton motor logging truck was recently built for a man in Cleveland, who has had it in service for nearly a year in the woods near Hixsonville in the southern part of Cuyahoga County, Ohio.

On a small scale, this truck has done the work of the logging locomotive, the skidder and the donkey engine. In addition it automatically loads the truck by its own power and then transfers its load from truck to flat car by that same power.

While there can be no direct comparison between the work of this single truck and the enormous tonnage capacity of log trains, a careful analysis of the work of this truck bearing in mind that it is merely a single unit, reveals interesting possibilities. It is built with a six-cylinder motor and in all other respects, except the wheels, it is of standard design. The driving wheels are built of steel, with a twenty-two inch tread having the usual corrugated surface of tractor wheels, and enabling the truck to run over rough air fields and soft ground such as will be encountered on any timber tract.

A power winch driven off the transmission of the truck, is built adjustable and controlled by a lever skidder to the brake and gear shifter. Loads as high as six tons have been carried without difficulty, although the rated capacity of the truck is five tons. By proper use of the power winch and a simple scheme of rope and chain tackle the crews have loaded 1,000 feet of lumber on the truck in twenty minutes. Furthermore, its remarkable capacity for loading is realized in many ways, notably in the salvage of fire specimens of hardwood, which frequently fall into ravines and cannot ordinarily be recovered except at prohibitive cost.

The customary haul of the truck is approximately five tons for an average distance of about six miles. On arrival at the railroad siding the rapidity with which the truck drops its load and pulls the logs upon freight cars by the use of its power drum and cable, produces a great saving of time and labor.

The logs ordinarily are dropped on the

ground and then rolled up on the cars. If no cars are available, the crew simply drops the load and returns to the woods, knowing that the loading operation can be done quickly by the truck when the cars are ready. The truck therefore has no idle minutes.

### The Log of a Horse Drawn Truck

**T**HE Electrical Engineering Department of the Massachusetts Institute of Technology has published a leaflet known as "Research Bulletin No. 2," which contains some interesting observations on the daily work of the horse, showing how much of the time the truck must stand idle while it is being loaded and unloaded.

A six-ton motor logging truck taking on a load of lumber.

A study has been made of freight delivery in Boston. Careful records were made of every movement of the vehicles from the time they left the stable in the morning until they returned at night. An analysis is published of the daily wagon performance based on eighteen days' observation of four different wagons handling miscellaneous freight. The average working day, or the time out of the stable, was 10.7 hours. It was found that 25 per cent of the day was spent at the railroad yards, 25 per cent of the day at warehouses, and the remainder of the day, or 41 per cent, on the street. Of this latter time, 13 per cent of the day was spent in traveling from and to the stable in the morning and the evening. The time spent in travel between warehouse and freight yards was 10 per cent of the day, during 15 per cent of which there was at least a partial load on the wagon. To illustrate these figures clearly and show how much of the time

the horse stands idle, we have prepared the accompanying drawing with the schedule laid out on a sun dial. Thirty-two per cent of 10.7 hours is 3.42 hours, or three hours and twenty-five minutes. This was the time spent at the railroad station, and it was made up of nearly 12 per cent for loading, about 7 per cent for unloading, and about 5 per cent for delays of different kinds. The actual time moving at the railroad station was but 11 per cent of the day. Not counting the time of travel to and from the stable, which as our dial shows amounted to 1.90 hours, or one hour and twenty-three minutes, only 3.21 working hours, or three hours and twelve minutes, were spent on the street, during two hours and two

but only during four and a quarter hours of moving. It can get to work and return to its garage in quicker time; it can move about in the railroad yards and maneuver into position for loading and unloading in less time than is taken by the horse drawn truck, and it can move from the railroad yards to the warehouse in less time, provided there is not too much congestion on the street. But the time of loading and unloading at the railroad yards and at the warehouses and the time taken out for meals would be the same if the driver is to have his noon hour. And so, although the motor truck may be much faster than the horse drawn vehicle, it can demonstrate its superiority only during a very small part of the day. It is for this reason that so much attention is being paid to the loading and unloading of motor trucks at the present time, for the longer the hours of moving the greater will be the superiority of the motor truck. Dumping bodies are used for unloading the trucks, and special loaders, and separate bodies which may be removed for loading and unloading. Everything, in fact, is being done to avoid delays of all kinds, so that the motor truck can be on the street as much as possible, and spend most of its time in active competition with the horse.

### Motor Trucks in Porto Rico

**T**HAT Porto Rico presents an excellent opportunity for an extensive use of motor trucks is the assertion of Mortimer Benington, commercial agent of the United States for Porto Rico. The little island, with its population of more than a million, now stands eleventh in importance of the export markets of the United States. Its own export business has increased from a yearly total of \$17,000,000 in 1901 to \$60,000,000 for the fiscal year ending June 30th last, which speaks well for American occupancy. The only railroad on the island skirts the shore, and as most of the products and produce come from the interior, an extensive system of highway transportation is essential. In the present system the cart is the principal transportation vehicle used. Motor trucks, however, have received a foot hold. There are now sixty-six on the island and their number is sure to increase rapidly. Road conditions in Porto Rico favor the use of motor trucks. There are over 800 miles of stone roads, and the main highways are unsurpassed anywhere in the world. This accounts for the fact that there are now over 1,000 motor vehicles of all types there, and that at the present rate of increase this number will be doubled in the next eighteen months.

How the working day of the horse is taken up with delays in loading and unloading, etc., with but little time in actual hauling.

(Continued from page 282.)

double of Corona Borealis is near the northwest corner of our map, and the bright star Vega near the northeast corner. With these as guides the other stars may easily be found.

The telescope observer will find much of interest in this region. In Corona Borealis  $\epsilon$  is a nearly equal pair, separable in a small telescope.  $\beta$  and  $\delta$  Sarpentes are also separable with moderate power.

In Hercules we may note the bright double stars  $\delta$  (whose components are moving in different directions in the sky and have no real connection) a (a very fine pair, of strongly contrasted colors, the principal star being brilliantly red), and the fainter but near doubles  $\eta$  Her- cules,  $\eta$  Hercules (with contrasted colors) and a Hercules, whose 9th magni- tude companion, 20 seconds apart, is itself double, but separable only with a power- ful instrument.

The bright star  $\epsilon$  Hercules is an inter- esting binary with a period of 55 years. In the component stars the brighter is little more than 1 second apart, so that a tele- scope of at least six inches aperture will be required to show them well.

About 5 degrees north of this—two thirds the way to the way to a Hercules—the map shows a faint object, which is visible even to the naked eye, and appears in a field-glass as a hazy round object. This is a great globular star-cluster, the finest in the northern sky, containing many thou- sands of stars. The view of this object which can be obtained with a small tele- scope falls far short of the magnificence of the photograph secured with large in- struments, but it is nevertheless well worth looking at.

Farther south and east  $\delta$  Sarpentes is a fine wide double, within the reach of a strong field-glass, and  $\eta$  Ophiuchus (at most exactly in R. A.) is a remark- able binary, now resolvable with three- inch aperture or less.  $\lambda$  Dra. in the northwest corner of the map, is full of interesting things. Vega, one of the whitest stars in the northern sky, has a faint companion of the tenth magnitude, which does not share in its proper motion, and is probably immeasurably more re- mote.

$\beta$  Lyrae is a very remarkable variable, composed of two very large stars of small density, which revolve about one another almost in contact in a period of about 13 days and mutually obscure one another. The neighboring star  $\gamma$  Lyrae affords an excellent standard of comparison, since the variable is almost equal to it at maxi- mum, and less than half as bright at mini- mum.

$\epsilon$  and  $\delta$  Lyrae are wide pairs, resolvable by a field-glass. Still more interesting is the famous "double-double" star Epsilon ( $\epsilon$ ) Lyrae, just northeast of Vega. The smallest optical power will split this into two, in fact, the two stars, which are 307 seconds apart can be seen separated by keen eyes without instrumental aid. With a three-inch telescope, each com- ponent is found to be double.

#### The Planets.

Mercury is evening star throughout July and is best visible in the early part of the month, setting about 8 50 P. M. Venus is morning star in Taurus, ris- ing about 2 A. M. She is at her greatest western elongation on the 3rd, and ap- pears in the telescope as a half moon.

Mars is a morning star, about 20 degrees west of Venus, but is far less con- spicuous. Jupiter is in opposition on the 6th, and is in sight all night, though very far south for observation in our latitude. Saturn is morning star in Taurus, and is in conjunction with Venus on the 21st, being 1 degree 15 minutes north of her. Uranus is in opposition on the 20th. He is then in Capricornus.

Neptune is in conjunction with the sun on the 16th, and is quite invisible.

The moon is near at midnight on the 6th, in her first quarter at 8 P. M. on the 10th, full at 1 A. M. on the 18th, and in her last quarter at 5 A. M. on the 26th, and to observe the earth on the 9th, and 25th, etc., on the 1st, 11th, 21st, etc.

## The Fag-Free "Fans" Wear B. V. D.

Cool and comfortable despite the grueling heat, the fag-free "fans" in the foreground wear Loose Fitting, Light Woven B. V. D. Coat Cut Undershirts and Knee Length Drawers, or Union Suits. Why don't you put on B. V. D. and "cool off"?

To get genuine B. V. D. get a good look at the label. On every B. V. D. Undergarment is sewed

(has Red Woven Label)

**MADE FOR THE B. V. D. BEST RETAIL TRADE**

(These Marks are 12 & 14 for 10 and 12 respectively)

Insert that your dealer sells you only underwear with the B. V. D. Label

B. V. D. Coat Cut Undershirt and Knee Length Drawers, 50c. 75c. \$1.00 and \$1.50 for the Ladies, 40c. 50c. 60c. 75c. 80c. 90c. 1.00 1.25 1.50 2.00 2.50 and \$3.00 for the Men.
